PART 1

Introduction

1

Introduction to the DS2 Language

Introduction to the DS2 Language

DS2 is a SAS proprietary programming language that is appropriate for advanced data manipulation. DS2 is included with the SAS Viya platform and intersects with the SAS DATA step. It also includes additional data types, including ANSI SQL data types, additional programming structure elements, and user-defined methods and packages.

Several DS2 language elements accept embedded FedSQL syntax, and the runtime-generated queries can exchange data interactively between DS2 and any supported database. This allows SQL preprocessing of input tables, which effectively combines the power of the two languages.

In the SAS Viya platform, DS2 programs can run in the following environments:

- SAS Cloud Analytic Services (CAS) server
- SAS Compute server
- SAS Event Stream Processing (ESP) server
- SAS Federation Server
- SAS Micro Analytic Service

SAS Federation Server is a separately licensed server that provides multi-user, standards-based, federated data access. SAS Micro Analytic Service is a memory-resident, high-performance program execution platform that supports in-stream data analysis and decision automation. It can be deployed as a micro-service, or it can run within a server process, such as an ESP, CAS, or Compute server. The service is available in SAS Intelligent Decisioning and SAS Model Manager, in addition to the SAS Event Stream Processing solution.

The DS2 procedure enables you to submit DS2 language statements from SAS Data and AI Studio (known as SAS Studio prior to 2026.06). For more information about PROC DS2, see Base SAS Procedures Guide.

Note: Because the DS2 language can be used with many data sources, the terms row, column, and table are used to describe the data elements. Comparing this to SAS DATA step terminology, a row corresponds to an observation, a column corresponds to a variable, and a table corresponds to a data set.

Running DS2 Programs

You can submit DS2 programs in one of the following ways.

- Through SAS Data and AI Studio (known as SAS Studio prior to 2026.06) using the DS2 procedure. The DS2 procedure can be used to run DS2 code in the SAS Compute server or on the CAS server. A single PROC DS2 step can contain several DS2 programs.

  For more information, see "DS2 Procedure" in *Base SAS Procedures Guide*.

- In SAS Data and AI Studio (known as SAS Studio prior to 2026.06) using the runDS2 action on the CAS server. The runDS2 action is used in conjunction with the CAS procedure.

  Note: Unless you are using Python or Lua, it is recommended that you use PROC DS2 to submit DS2 code to the CAS server.

  For more information, see "DS2 Action Set" in *SAS Viya Platform: System Programming Guide* and "DS2 in CAS: Concepts" in *SAS DS2 Programmer's Guide*.

- In SAS Federation Server using the SAS LIBNAME engine for SAS Federation Server. For more information, see *SAS LIBNAME Engine for SAS Federation Server: User's Guide*.

- In SAS Event Stream Processing, SAS Intelligent Decisioning, and SAS Model Manager by using SAS Micro Analytic Service. For more information, see About Using SAS Micro Analytic Service and DS2 Programming for SAS Micro Analytic Service in *SAS Micro Analytic Service: Programming and Administration Guide*.

Supported Data Sources

DS2 can access the following data sources:

- Amazon Redshift
- CAS tables
- DB2 for the UNIX operating environment
- Google BigQuery
- Greenplum
- Hadoop (Hive)
- Impala
- databases that are compliant with JDBC (such as PostgreSQL)
- Memory Data Store (MDS)
- Microsoft SQL Server
- MongoDB *
- MySQL (includes MySQL 8 Server)
- Netezza
- databases that are compliant with ODBC (such as Microsoft SQL Server)
- Oracle
- PostgreSQL
- Salesforce
- SAP (Read-only)
- SAP HANA
- SAP IQ
- SAS data sets
- SAS Scalable Performance Data Engine (SPD Engine) data set
- SAS Scalable Performance Data Server (SPD Server) tables in the UNIX operating environment
- SingleStore
- Snowflake
- Spark
- Teradata for UNIX operating environment
- Vertica
- Yellowbrick

Note: The following data sources are not supported:

- Informix
- OLEDB
- SAP ASE

DS2 can operate on all data sources except MDS and SPD Server in the SAS programming runtime environment or on the CAS Server.

*The MongoDB data source has special requirements for creating tables. Depending on your data, you might want to create these tables: a root table, a parent table, or a child table. You can create only root tables with DS2. To create parent and child tables, you must use FedSQL. See the information about MongoDB in *SAS/ACCESS for Relational Databases: Reference*.

The DS2 procedure and SAS Federation Server support different data sources. See *Base SAS Procedures Guide* and *SAS Federation Server: Administrator's Guide* for information about the data sources that each one supports.

For information about accessing the data sources, see *SAS/ACCESS for Relational Databases: Reference* and *SAS/ACCESS for Nonrelational Databases: Reference*, as appropriate.

Intended Audience

The information in this document is intended for the following users who perform in these roles:

- **Application developers** who write the client applications. They write applications that create tables, bulk load tables, manipulate tables, and query data.
- **Database administrators** who design and implement the client/server environment. They administer the data by designing the databases and setting up the data source metadata. That is, database administrators build the data model.
- **SAS programmers** who want or need to take advantage of the advanced features of the DS2 language: increased numeric precision, parallel computation for CPU-bound processes, using explicit pass-through SQL queries as direct input to a DATA step process, or in-database processing in big data environments.

When to Use DS2

Typically, DS2 programs are written for applications that carry out the following actions:

- require the precision that results from using the new supported data types
- benefit from the new programming elements of the DS2 language, such as variable scoping, user-defined methods and packages, and threaded processing support
- need to execute SAS FedSQL from within the DS2 program
- need to execute outside a SAS session (for example, on SAS Federation Server)

Converting DATA Step Programs to DS2 Programs

You can use the DSTODS2 procedure to translate the DATA step code into DS2. Not all DATA step code is supported for translation, and some manual translation might be required. Code lines that cannot be translated are placed in comments. For more information, see the "DSTODS2 Procedure" in *Base SAS Procedures Guide*.

After you have converted the DATA step code to DS2 and ensured that your program is syntactically complete, you can use the DS2 procedure to run your program in the SAS Viya platform.

Syntax Conventions for the DS2 Language

Typographic Conventions

Type styles have special meanings when used in the documentation of the DS2 language syntax.

UPPERCASE BOLD
identifies DS2 keywords such the names of statements and functions (for example, PUT).

UPPERCASE ROMAN
identifies arguments and values that are literals (for example, FROM).

italic
identifies arguments or values that you supply. Items in italic can represent user-supplied values that are either one of the following.

- nonliteral values assigned to an argument (for example, ALTER=*alter-password*).
- nonliteral arguments (for example, KEEP=(*column-list*).

If more than one of an item in italics can be used, the items are expressed as *item* [, ...*item*].

`monospace`
identifies examples of SAS code.

Syntax Conventions

This documentation uses the Backus-Naur Form (BNF), specifically the same syntax notation used by Jim Melton in *SQL:1999 Understanding Relational Language Components*.

The main difference between traditional SAS syntax and the syntax that is used in the DS2 language reference documentation is in how optional syntax arguments are displayed. In traditional SAS syntax, angle brackets (< >) are used to denote optional syntax. In DS2 language syntax, square brackets ([ ]) are used to denote optional syntax and angle brackets are used to denote non-terminal components.

The following symbols are used in the DS2 language syntax.

::=
This symbol can be interpreted as “consists of” or “is defined as”.

<>
Angle brackets identify a non-terminal component (that is, a syntax component that can be further resolved into lower level syntax grammar).

[ ]
Square brackets identify optional arguments. Any argument that is not enclosed in square brackets is a required argument. Do not enter square brackets unless they are preceded by a backward slash (\), which denotes that they are literal.

{ }
Braces provide a method to distinguish required multi-word arguments. Do not enter braces unless they are preceded by a backward slash (\), which denotes that they are literal.

|
A vertical bar indicates that you can choose one value from a group. Values that are separated by bars are mutually exclusive.

...
: An ellipsis indicates that the argument or group of arguments that follow the ellipsis can be repeated any number of times. If the ellipsis and the following arguments are enclosed in square brackets, they are optional.

\
: A backward slash indicates that the next character is a literal.

The following examples illustrate the syntax conventions that are described in this section. These examples contain selected syntax elements, not the complete syntax.

```
1 SET 2 <table-reference> [… [<table-reference>] [INDSNAME=variable];
   [3 BY [DESCENDING] 4 column [5 ...[DESCENDING] column];
  6 <table-reference>:::=
  {table (table-options)} 7 | 8 \{sql-text 8 \}
```

1 SET is in uppercase bold because it is the name of the statement.

2 <table-reference> is in angle brackets because it is a non-terminal argument that is further resolved into lower level syntax grammar. You must supply at least one <table-reference>.

3 BY and DESCENDING are in uppercase roman because they are literal arguments. DESCENDING is in square brackets because it is an optional argument.

4 *column* is in italics because it is an argument that you can supply.

5 The square brackets and ellipsis around the second instance of *column* indicate that you can repeat this argument any number of times as long as the arguments are separated by commas.

6 The <table-reference>::= non-terminal argument syntax is read as follows: A <table-reference> consists of a table name and table options or embedded SQL text.

7 The vertical bar (|) indicates you can supply either *table* [*table-options*] or *sql-text*, but not both.

8 The backslash (\) before the braces around *sql-text* indicate that those braces are literals and must be entered.

PART 2

Getting Started

2

DS2 and the DATA Step

What Is DS2?

DS2 is a SAS proprietary programming language that is used for data manipulation and data modeling applications. The DS2 language shares core features with the DATA step. However, DS2 has capabilities that are not provided by the DATA step.

DS2 is a procedural language that has variables and scope, methods, packages, control flow statements, table I/O statements, and parallel programming statements. Methods and packages give DS2 modularity and data encapsulation. DS2 enables you to insert SQL directly into the SET statement, thus blending the power of two powerful data manipulation languages.

Similarities between DS2 and the DATA Step

DS2 and the DATA step share many language elements, and those elements behave very much the same

- SAS formats.
- Most SAS functions.
- SAS statements such as DATA, SET, KEEP, DROP, RUN, BY, RETAIN, PUT, OUTPUT, DO, IF-THEN/ELSE, Sum, and others.

- DATA step keywords are included in the list of DS2 keywords.

You can perform many DATA step tasks using DS2:

- process variable arrays, multi-dimensional arrays, and hash tables
- convert between data types
- work with expressions
- calculate date and time values
- process missing values

Note: All supported DS2 syntax is covered in this document. Any syntax appearing in other SAS documentation is not part of the supported DS2 syntax unless it is also documented here.

Differences between DS2 and the DATA Step

Table 2.1 *Comparison by Topic*

Topic	DATA Step	DS2
Executable statements	All executable statements of a DATA step reside in a single code block.	Executable statements of a DS2 program reside in method code blocks. A DS2 program is composed of one or more method code blocks.
Scope	No concept of scope. All variables are global.	Variables that are declared in a method have local scope. All other identifiers have global scope. There are three types of global scope: - data program - thread program - package
Declaring variables	Variables need not be explicitly declared. Variables can be created by assignment. The data type of a variable is determined	Variables are declared using the DECLARE statement, which also determines the data type and scope attributes of the variable.

Topic	DATA Step	DS2
	by the context of how it is first used. All variables have global scope. Variables are also defined when the SET statement is used.	Variables can be declared by assignment, but a best practice is to enforce variable declaration strict mode by setting the system option DS2SCOND=ERROR or the PROC DS2 option SCOND=ERROR. Warning messages are issued for undeclared variables. Global variables are also defined when the MERGE, SET, or SET FROM statement is used.
Variable attributes	Establishing the attributes of a variable requires the use of the LENGTH, FORMAT, INFORMAT, LABEL, and ATTRIB statements.	Establishing the attributes of a variable requires only the DECLARE statement and its HAVING clause.
Data types	Two data types are supported: numeric and character. Numeric data is floating point from 3 to 8 bytes. Character data is fixed or variable length.	Most ANSI SQL data types are supported. Numeric types of varying sizes and precision. Character data types can be fixed length and variable length. DS2 supports ANSI date, time, and timestamp data types, but can also process SAS date, time, and datetime values using conversion functions.
Keywords and reserved words	No reserved keywords.	Keywords are reserved words. See "Reserved Words in the DS2 Language" in *SAS DS2 Programmer's Guide* for the list of reserved words. Reserved words can be used as identifiers by enclosing them in double quotation marks.
Quotation marks	Single or double quotation marks specify a character constant. Here are two examples that are equivalent: `"Tom"` `'Tom'` Table and column names that have a special character in their names (delimited identifiers) are	ANSI SQL quoting standards are followed: - Single quotation marks specify a character constant. - Double quotation marks specify a delimited identifier. For example, `"Tom"` is a delimited identifier and `'Tom'` is a character constant.

Topic	DATA Step	DS2
	specified as name literals (quotation marks followed by the letter n). For example, "Tom"n is a SAS name literal.	
Text that is resolved from macro variable references	Double quotation marks are required to reference the resolved value of a macro variable. Here is an example: `my_host = "&syshostname";`	Because ANSI SQL quoting standards are followed, double quotation marks denote delimited identifiers. To reference a macro variable in a literal string, use the %TSLIT macro function. Here is an example: `my_host = %tslit(&syshostname);`
PUT statement	The DATA step and DS2 both have a PUT statement for writing lines to the SAS log. Both the DATA step and DS2 PUT statements support writing formatted variable values and named variable values . DATA step also supports writing to specified columns and using variable lists.	DS2 does not support writing to specified columns and using variable lists.
Missing and null values	Supports only missing values. No concept of a null value.	Supports both missing and null values. Nulls, from a database, can be processed in ANSI mode or in SAS mode.
Automatic data type conversion	SAS tries to convert between character and numeric data types when one data type is assigned to a variable of the other data type.	Has many more rules because of many more data types. Most data types are coercible. DATE, TIME, TIMESTAMP, BINARY, and VARBINARY data types are not coercible.
SQL language statements	Available in PROC SQL, not in the DATA step.	The DS2 SET statement, SQLSTMT package, and SQLEXEC function accept FedSQL statements. For more information, see "Using DS2 and FedSQL" in *SAS DS2 Programmer's Guide*.
SAS macros	In Base SAS, the DATA step can interact with a macro at run time	SAS macro processing is available to DS2 programs that are submitted using PROC DS2.

Topic	DATA Step	DS2
	using the DATA step call routines for macros. The SAS Macro Facility does not run within Cloud Analytic Services (CAS). Macros specified in DATA steps that are submitted to the CAS server are preprocessed by the macro facility before the DATA step is sent to the CAS server.	The macros are preprocessed by the SAS Macro Facility before the DS2 program is executed, whether the DS program is executed locally, or remotely on the CAS server or SAS Federation Server. DS2 does not support the DATA step call routines for macros.SAS macro support is not available when DS2 runs in grid computing environments such as in-database processing using the SAS Embedded Process.
Overwriting data sets	The DATA step, like SAS procedures, overwrites an existing data set. `data one;` `  set two;` `run;` `data one;` `  set three;` `run;`	In keeping with SQL and database standards, DS2 does not automatically overwrite existing data sets. You must use the **`overwrite`** table option. Here is an example. `proc ds2;` `data one;` `  method run();` `  set two;` `  end;` `enddata;` `run;` `data one / overwrite=yes;` `  method run();` `  set three;` `  end;` `enddata;` `run;` `quit;`
Reading from and writing to the same data set	Permits reading from and writing to the same data set name in a DATA or PROC step. `data one;` `  set one;` `  s = s + 1;` `run;`	DS2 does not allow reading from and writing to the same table in a single data program. In database fashion, the user must create a temporary table, drop the original table, and then rename the temporary table. This example is equivalent to what SAS does to implement the appearance of reading from and writing to the same data set at the successful conclusion of a DATA or PROC step. `proc ds2;`

Topic	DATA Step	DS2
		`data temp001;` `  method run();` `  set one;` `  s = s * 1;` `  end;` `enddata;` `run;` `quit;` `proc fedsql;` `  drop table one;` `  alter table temp001 rename to one;` `run;` `quit;`
SAS data set options	The DATA step provides SAS data set options to enable you to specify actions that apply to a specific data set. SAS data set options are specified in parentheses after a SAS data set name. Data set options provide functionality in multiple categories, including data access, data set control, observation control, user control of SAS index usage, and variable control, among others.	DS2 provides table options that are analogous to data set options for variable control. For example, the DROP=, KEEP=, IN=, and RENAME= data set options are supported as table options in DS2. DS2 does not provide table options for observation control. Instead, embedded SQL statements can be used to perform observation (row) control. Table options for data access and table control are limited and are dependent on the data source. See "DS2 Statement Table Options by Data Source" on page 1475. Table options are either enclosed in parentheses or preceded by a forward slash (/), depending on which statement they are used in. Table options that are preceded by the forward slash should be placed at the end of the statement .
Filtering the rows that are returned from a data set	In the DATA step, row selection criteria are specified in the WHERE statement or the WHERE= data set option. Here is an example of the WHERE data set option: `data ds1;` `  set test(where=(x=2));` `  put x=;` `run;`	In DS2, you use embedded FedSQL to specify row selection criteria. Use of FedSQL statements is supported in the **`sql-text`** argument of the SET statement and as a constructor in the SQLSTMT predefined package. Here is an example of a FedSQL SELECT statement that is specified in the DS2 SET statement.

Topic	DATA Step	DS2
	`x=2`	`proc ds2;` `  data ds2;` `  method run();` `  set {select x from test where x=2};` `  put x=;` `  end;` `  enddata;` `  run;` `quit;` `x=2` **Note:** When used in the SET statement, embedded SQL statements are specified within curly braces ({}).
Limiting processing to a set of a contiguous rows	In the DATA step, the FIRSTOBS= and OBS= data set options are used to specify the first and last observations that are processed. `data ds1;` `  set study(firstobs=5 obs=10);` `run;` `proc print data=ds1;` `  run;`	In DS2, specify the OFFSET and LIMIT clauses in an embedded FedSQL SELECT statement. OFFSET specifies the number of rows to skip before the SELECT statement starts to return rows. LIMIT specifies the number of rows that the SELECT statement can return. `proc ds2;` `  data ds2;` `  method run();` `  set {select x from test offset 5 limit 6};` `  end;` `  enddata;` `  run;` `quit;` `proc print data=ds2;` `run;`
Accessing CAS tables	Both DS2 programs run by either PROC DS2 or the ds2.runds2 action and DATA step programs run by either the DATA step or the datastep.runcode action can use caslibs for accessing CAS tables. In addition, DATA step supports CAS librefs when the program is submitted via the DATA step.	DS2 does not support CAS librefs. DS2 returns an error if you attempt to use a CAS libref with PROC DS2.
Specifying that a program run remotely in CAS	Both PROC DS2 and the DATA Step support the SESSREF and SESSUUID options for explicitly	DS2 programs are explicitly submitted to CAS.

Topic	DATA Step	DS2
	specifying that the program should be run remotely in a CAS server rather than locally in the SAS session. In addition, the DATA step has the feature of implicitly deciding to run a program remotely in a CAS server if the input (SET) and output (DATA) tables reside in a CAS server.	
Multi-threaded processing	Multiple threads are available only in CAS.	Multiple threads are supported in all of the environments in which DS2 runs (SAS programming runtime environment, CAS, and SAS Federation Server). Threaded code blocks are defined using the THREAD statement.
User-defined functions	PROC FCMP enables users to create and store SAS functions that can be called from DATA steps.	User-defined function support is built into the DS2 language with the METHOD statement. DS2 provides the ability to group and store functions using the PACKAGE statement for reuse by multiple DS2 programs. DS2 also provides the FCMP package for calling SAS functions stored by PROC FCMP.
Calling FCMP functions	The SAS system option CMPLIB= specifies where to look for previously compiled functions and subroutines. All procedures (including FCMP) that support the use of FCMP functions and subroutines use this system option. In CAS, CMPLIB is a session option.	DS2 does not support the CMPLIB system option or session option. To call FCMP functions, you use the FCMP package. DS2 can call functions defined by PROC FCMP that are stored in a data set. The DS2 FCMP package provides the ability to load and call the FCMP functions from a data set. For more information, see "Using the FCMP Package" in *SAS DS2 Programmer's Guide*.

3

Learning by Example: Using the Sample Programs

About the Getting Started Sample Programs

How to Run the Sample Programs

You can run all of the getting started sample programs in this chapter from a SAS session using the DS2 procedure. Each sample program is a complete program; simply copy a program into your SAS session and submit it.

The getting started sample programs do not rely on a pre-existing data source, nor do they require a connection to a database. When data is needed, the program creates it.

Recommended Options

All of the getting started sample programs run correctly with the following SAS system option global statement:

```
options DS2SCOND=ERROR;
```

You can also override the default DS2SCOND option setting, WARNING, by specifying the following DS2 procedure option:

```
proc ds2 SCOND=ERROR;
```

The ERROR setting enforces variable declaration strict mode. In strict mode, a compilation error occurs if you do not explicitly declare a variable.

> **TIP** Variable declaration strict mode is the recommended best practice when writing DS2 programs.

Unlike the DATA step, DS2 protects existing tables from being overwritten. However, if you are developing or changing a table, package, or thread, you need the ability to overwrite these tables.

The OVERWRITE=YES table option enables you to overwrite the table. Here are some examples:

```
package foo /overwrite=yes;
thread work.foo(int x) /overwrite=yes;
data foo (overwrite=yes);
data my_data /overwrite=yes;
```

> **TIP** The OVERWRITE= option requires the forward slash (/) syntax with the PACKAGE and THREAD statements. You can use either the / syntax or the parentheses syntax with the DATA statement.

By default, the value of the OVERWRITE= table option is NO.

Using the DS2 Procedure

When you use the DS2 procedure to write a program, place your code within the following framework:

```
options ds2scond=error;
proc ds2;
... DS2 statements ...
```

```
run;
quit;
```

For more information, see "DS2 Procedure" in *Base SAS Procedures Guide*.

Verifying Access to DS2

In a SAS session, run the following program:

```
proc ds2;
quit;
```

The following is written to the log:

```
3317  proc ds2;
3318  quit;

NOTE: PROCEDURE DS2 used (Total process time):
      real time           0.08 seconds
      cpu time            0.04 seconds
```

If you see an error message, such as `ERROR: Procedure DS2 not found`, see your system administrator.

Your First Sample Programs

Overview of the Sample Programs

Because many programmers prefer to learn by reading code, this chapter presents several sample programs before explaining the language constructs that the programs use. The sample programs help you quickly learn DS2 syntax and concepts so that you avoid common pitfalls.

The first sample program is the "Hello World!" program. Subsequent sample programs are variations on this program. Some variations might seem needlessly complex. The point is to demonstrate common structural programming elements of the DS2 language, not the best way to write the "Hello World!" program.

Note: Although the sample programs introduce syntax and concepts in order of increasing complexity, they do not rely on a particular order to be fully understood.

Example 1: "Hello World!" Program – In a System Method

Here is one way to code the "Hello World!" program. This program writes "Hello World!" to the SAS log from the INIT( ) system method.

What to Notice

- The variable MESSAGE has local scope because it is declared in the INIT( ) method.
- The INIT( ) system method automatically runs first in a DS2 data program.
- Single quotation marks delimit the character constant.
- The libs=work option limits the connection string to use only the SAS Work library. For more information, see the "PROC DS2 Statement" in *Base SAS Procedures Guide*.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
data _null_;

  /* init() - system method */
  method init();
    declare varchar(16) message; /* method (local) scope */
    message = 'Hello World!';
    put message;
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
Hello World!
```

Example 2: "Hello World!" Program – In a User-Defined Method

This variation of the program writes "Hello World!" to the SAS log from a user-defined method.

What to Notice

- Because the variable MESSAGE has global scope in the data program, all methods can access it.
- The INIT( ) system method calls the user-defined GREET( ) method to write the message to the log.

  Note: The GREET( ) method is defined before the method that references it. Otherwise, a compilation error would occur.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
data _null_;
  dcl varchar(16) message; /* data program (global) scope */

  /* greet() - user-defined method */
  method greet();
    put message;
  end;

  /* init() - automatically runs first in the data program.*/
  method init();
    message = 'Hello World';
    message = cat(message, '!');
    greet();
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
Hello World!
```

Example 3: “Hello World!” Program – In a User-Defined Package

This variation of the program writes “Hello World!” and other messages to the SAS log through a user-defined package.

What to Notice

- The PACKAGE statement uses the OVERWRITE=YES table option so that you can run the program more than once without error. By default, DS2 protects existing packages from being overwritten.
- The variable MESSAGE is declared inside the package, not in the data program.

What to Notice

- The package contains a constructor and two package methods to manipulate the greeting string.

  The FORWARD statement enables the SETMESSAGE( ) method to be defined after methods that reference it. Otherwise, a compilation error would occur.

  The SETMESSAGE( ) method uses the THIS operator to distinguish the global variable MESSAGE from the parameter that is named MESSAGE.
- In the data program, the DECLARE PACKAGE statement simultaneously declares a package variable and constructs an instance of the package using the package constructor.
- Dot notation provides access to package methods from the data program.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
  dcl varchar(100) message;    /* package (global) scope */
  FORWARD setMessage;

  /* greeting(MESSAGE) - constructor */
  method greeting(varchar(100) message);
    setMessage(message);
  end;

  method greet();
    put message;
  end;

  method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
  end;
endpackage;
run;

/* data program */
data _null_;
  /* declares and instantiates an instance of the GREETING package */
  dcl package greeting g('Hello World!');  /* data program (global) scope */

  /* init() - automatically runs first in the data program.*/
  method init();
    g.greet();
    g.setMessage('What''s new?'); /* change greeting */
    g.greet();
end;
enddata;
run;
quit;
```

The following is written to the log:

```
Hello World!
What's new?
```

Example 4: “Hello World!” Program – In the Implicit Loop

This variation contains two data programs: one to create a table of greetings and one to process the table.

What to Notice

- In the first data program, the DATA statement uses the OVERWRITE=YES table option so that you can run the program more than once without error. By default, DS2 protects existing packages from being overwritten.
- The GREETING package has two constructors: a default constructor and one that accepts an argument.
- The second data program uses the two-step method for instantiating a package:
  1. The DECLARE PACKAGE statement declares a global package variable.
  2. The INIT( ) method uses the _NEW_ operator to create the package instance.
- In the second data program, the RUN( ) method uses the implicit loop of the SET statement to read and process the MESSAGE variable from each row in the table.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
/* data program # 1 - Creates a table of greetings */
data work.greetings /overwrite=yes;
  dcl char(100) message; /* data program (global) scope */

  method init();
    message = 'Hello World!'; output;
    message = 'What''s new?'; output;
    message = 'Good-bye World!'; output;
  end;
enddata;
run;
quit;

proc ds2;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
  dcl varchar(100) message;    /* package (global) scope */
  forward setMessage;
```

```
  /* greeting() - default constructor */
  method greeting();
    setMessage('This is the default greeting.');
  end;

  /* greeting(MESSAGE) - constructor */
  method greeting(varchar(100) message);
    setMessage(message);
  end;

  method greet();
    put message;
  end;

  method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
  end;
endpackage;
run;

/* data program #2 */
data _null_;
  dcl package greeting g; /* package (global) scope */

  /* init() - automatically runs first in the data program. */
  method init();
     g = _NEW_ greeting();
    g.greet();
  end;

  /* run() - automatically runs after INIT() completes. */
  method run();
    /* Implicit loop reads each row from the table */
    set work.greetings;
    g.setMessage(message); /* MESSAGE is read from row by SET statement */
    g.greet();
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
This is the default greeting.
Hello World!

What's new?

Good-bye World!
```

Example 5: “Hello World!” Program – In Multiple Package Instances

This version of the program uses multiple instantiations of packages to obtain the same results as Example 4, without creating a table.

What to Notice

- The GREETING package is identical to the GREETING package in the previous example. Because the package already exists, the package block could have been omitted from this program.
- You can use different constructors in the same DECLARE PACKAGE statement.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
  dcl varchar(100) message;    /* package (global) scope */
  FORWARD setMessage;

  /* greeting() - default constructor */
  method greeting();
    setMessage('This is the default greeting.');
  end;

  /* greeting(MESSAGE) - constructor */
  method greeting(varchar(100) message);
    setMessage(message);
  end;

  method greet();
    put message;
  end;

  method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
  end;
endpackage;
run;

/* data program */
data _null_;
  dcl package greeting
  g0() g1('Hello World!') g2('What''s new?') g3('Good-bye World!');
```

```
  /* init() - automatically runs first in the data program.*/
  method init();
    g0.greet();
    g1.greet();
    g2.greet();
    g3.greet();
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
This is the default greeting.
Hello World!
What's new?
Good-bye World!
```

Example 6: “Hello World!” Program – In an Array Package Variable

This version of the program uses an array package variable to obtain the same results as Examples 4 and 5.

What to Notice

- The GREETING package is identical to the GREETING package in the previous examples.
- The DECLARE PACKAGE statement declares an array package variable. The array package variable enables you to group multiple package instances into one variable.
- A package instance is created and assigned to each element of the array package variable in the DECLARE PACKAGE statement using constructors. In this example, a message is specified in each constructor call, except for the first, which will store the default message.
- A DO loop iterates through each element of the array package variable using the DIM function. The GREET method from package GREETINGS is called on each package instance using dot notation to print the messages to the log.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2;
/* GREETING - User-defined package that writes a message to the SAS
log */
package greeting /overwrite=yes;
  dcl varchar(100) message;    /* package (global) scope */
  FORWARD setMessage;
```

```
  /* greeting() - default constructor */
  method greeting();
    setMessage('This is the default greeting.');
  end;

  /* greeting(MESSAGE) - constructor */
  method greeting(varchar(100) message);
    setMessage(message);
  end;

  method greet();
    put message;
  end;

  method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
  end;
endpackage;
run;

data _null_;
/* init() - automatically runs first in the data program.*/
 method init();
/* declare array package variable with constructor arguments */
   dcl package greeting garray[4] := [(), ('Hello World!'),
('What''s new?'), ('Good-bye World!')];
   dcl int i;

   do i = 1 to dim(garray);
     garray[i].greet();
   end;
 end;
enddata;
run;
quit;
```

The following is written to the log:

```
This is the default greeting.
Hello World!
What's new?
Good-bye World!
```

Example 7: “Hello World!” Program – Using a Thread

This version of the program uses a thread to read a table and pass variables to the data program.

What to Notice

- This single DS2 program includes two data programs, a package, and a thread program.
- The data program specifies two threads in the SET FROM statement.
- In the thread program, the RUN( ) method uses the implicit loop of the SET statement to read and process each MESSAGE variable from the table.
- In the data program, the RUN( ) method uses the implicit loop of the SET FROM statement to read and process each MESSAGE variable from the thread program.
- In the log, the thread program's TERM( ) output shows that the thread program ran twice, once per thread. In addition, the value of _N_ indicates the number of times that the RUN( ) method executed on behalf of each thread.

In a SAS session, copy or enter the following program. Then, submit it.

```
proc ds2 libs=work;
/* data program #1 - Creates a table of greetings */
data work.greetings /overwrite=yes;
  dcl char(100) message; /* data program (global) scope */

  method init();
    message = 'Hello World!'; output;
    message = 'What''s new?'; output;
    message = 'Good-bye World!'; output;
  end;
enddata;
run;

/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
  dcl varchar(100) message;    /* package (global) scope */
  forward setMessage;

  /* greeting() - default constructor */
  method greeting();
    setMessage('This is the default greeting.');
  end;

  /* greeting(MESSAGE) - constructor */
  method greeting(varchar(100) message);
    setMessage(message);
  end;

  method greet();
    put message;
  end;

  method setMessage(varchar(100) message);
    /* Must use THIS. to distinguish global */
    /* variable MESSAGE from parameter named MESSAGE. */
    this.message = message;
  end;
endpackage;
```

```
run;

/* thread program - Read the table */
thread work.t /overwrite=yes;

  /* run() - system method */
  method run();
    set work.greetings;
    output; /* output variables to calling program */
  end;

  /* term() - system method */
  method term();
    put _all_;
  end;
endthread;
run;

/* data program #2 */
data _null_;
   dcl package greeting g; /* data program (global) scope */
   dcl thread work.t t; /* data program (global) scope */

  /* init() - automatically runs first in the data program. */
   method init();
      g = _NEW_ greeting();
      g.greet();
   end;

  /* run() - automatically runs after INIT() completes. */
  method run();
      /* Implicit loop reads each row from the table */
      set from t threads=2;
      g.setMessage(message); /* MESSAGE read from row by SET FROM stmt */
      g.greet();
   end;
enddata;
run;
quit;
```

The following is written to the log:

```
This is the default greeting.
_N_=4 message=Good-bye World!

_N_=1 message=

Hello World!

What's new?

Good-bye World!
```

Building Blocks of DS2 Programs

Basic DS2 Language Concepts

Introducing DS2 Data Types

Unlike the SAS DATA step language, DS2 supports many of the ANSI SQL data types that are native to the data sources that SAS supports. Thus, you can declare DS2 variables that do not require data type conversions to access data that is stored in a data source. The ability to avoid data type conversions enables you to move data efficiently to and from a database or other data source.

Note: The types of data that you can store depend on the native types that your data source supports.

For more information, see "DS2 Data Types" in *SAS DS2 Programmer's Guide*.

The following table summarizes factors to consider when choosing DS2 data types.

Table 4.1 *DS2 Data Types: Quick Reference*

DS2 Data Type Category	Considerations
Character	CHAR(n) and VARCHAR(n) use one byte per character. NCHAR(n) and NVARCHAR(n), which handle Unicode national language character sets, use two or four bytes per multibyte character. When you specify the length of a variable, *n*, the length determines the size of a fixed-length variable or the maximum size of a varying-length variable. **Note:** Fixed-length CHAR(n) is the equivalent of a DATA step character variable, where *n* is the number of characters. It is also the default type for an undeclared DS2 character variable.
Fractional numeric	DECIMAL(*p,s*) (alias: NUMERIC) has exact precision. Other fractional numeric types include DOUBLE, FLOAT(*p*), and REAL (single-precision floating point) and are considered approximate. **Note:** DOUBLE is the equivalent of a DATA step numeric variable. It is also the default type for an undeclared DS2 numeric variable.
Integer numeric	Signed, exact whole numbers with varying storage sizes: TINYINT (-128 to 127) – 1 byte SMALLINT (-32,768 to 32,767) – 2 bytes INTEGER (-2,147,483,648 to 2,147,483,647) – 4 bytes BIGINT (-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807) – 8 bytes
Binary	BINARY(*n*) is fixed length. VARBINARY(*n*) is variable length.
Date and time	DS2 supports ANSI date, time, and timestamp data types, but can also process SAS date, time, and datetime values using these conversion functions: ■ TO_DATE casts a SAS numeric date to a DS2 DATE ■ TO_TIME casts a SAS numeric time to a DS2 TIME ■ TO_TIMESTAMP casts a SAS numeric datetime to a DS2 TIMESTAMP ■ TO_DOUBLE

DS2 Data Type Category	Considerations
	casts a DS2 DATE, TIME, or TIMESTAMP to a SAS numeric date, time, or datetime

Automatic Conversions of Data Types

About Automatic Conversions

To avoid unintended results, you must understand the DS2 rules for automatic data type conversion.

CAUTION
A type conversion can lead to the loss of data or precision, or both. Data type conversions are especially critical if you save DS2 data types in SAS data sets, because SAS data sets support only two data types. That is, DS2 variables might be automatically converted to either fixed-length character or numeric double.

An automatic type conversion occurs under the following circumstances:

- A character type is used in a numeric expression.
- A numeric type is used in a character expression.
- A call to a method supplies an argument value that does not exactly match the signature of the method.
- The types of the operands differ in a logical, arithmetic, relational, or concatenation expression.
- A DS2 data type is saved to a data source that does not support the type.

Coercion and Precedence

DS2 uses type coercion and precedence rules to determine the resulting data type for a conversion:

- Coercible data types can automatically convert to multiple data types.
- Non-coercible data types automatically convert to only character data types.
- Precedence determines the conversion type when an expression contains more than one data type.

For more information, see "DS2 Type Conversions" in *SAS DS2 Programmer's Guide*.

Conversion of Nulls and Missing Values

The mode that you use to process null and missing values can affect your data. The default mode for processing nulls and missing values, either SAS mode or ANSI mode, depends on the environment in which you submit your DS2 program and the options that you choose. For example, by default, the DS2 procedure processes data in SAS mode. The SAS Federation Server processes data in ANSI mode.

CAUTION
During multiple conversions, it is possible to lose the original meaning of data. This is particularly true in the values of SAS special missing values (._, .A-.Z).

For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

DS2 Programming Blocks and Scope

A programming block defines a section of a DS2 program that encapsulates variables and code. Programming blocks encourage the creation of modular, reusable code. In addition, a programming block defines the scope of identifiers within that block. In DS2, it is possible for variables to have the same name and data type, as long as they have different scope.

The following table summarizes the characteristics of DS2 programming blocks and scope.

Table 4.2 *DS2 Programming Blocks and Scope: Quick Reference*

Block	Delimiters	Scope
Data program	DATA...ENDDATA	Variables that are declared at the top of this programming block have global scope within the data program. In addition, variables that the SET statement references have global scope. Unless explicitly dropped, global variables in a data program are included in the program data vector (PDV). **Note:** Global variables exist for the duration of the data program.
Package	PACKAGE...ENDPACKAGE	Variables that are declared at the top of this programming block have global scope within the package. Package-scope variables are not included in the PDV of a data program that is using an instance of the package.

Block	Delimiters	Scope
		Note: Package-scope global variables exist for the duration of the package instance.
Thread program	THREAD...ENDTHREAD	Variables that are declared at the top of this programming block have global scope within the thread program. In addition, variables that the SET statement references have global scope. Unless explicitly dropped, global variables in a thread program are included in the thread output set. **Note:** Thread-scope global variables exist for the duration of the thread program instance, but they can be passed to the SET FROM statement in the data program.
Method	METHOD...END	A method is a subblock of a data program, package, or thread program. Method names have global scope within the enclosing block. Variables that are declared at the top of this programming block have local scope. Local variables are not included in the PDV. **Note:** Local variables exist for the duration of the method call.
DO loop	DO...END	Not applicable.

TIP Although method names have global scope, to forward reference a method, use the FORWARD statement at the top of the outer programming block. For more information, see "FORWARD Statement" on page 1373.

As the preceding table shows, there are three types of global scope:

- Data program
- Package
- Thread program

Variable Declaration in DS2

Implicit Declaration of Variables

As in SAS DATA step programming, DS2 enables you to implicitly create global variables by assignment. However, this is not recommended for these reasons:

- Subtle errors can occur (for example, if a variable name is misspelled).
- The data types of such variables are limited to DOUBLE and CHAR(*n*).
- Undeclared variables might make your program difficult for others to read and understand.

Variable Declaration with the DECLARE Statement

Unlike SAS DATA step programming, DS2 enables you to explicitly declare variables using the DECLARE statement. You can control all attributes of a variable in a single DECLARE statement.

The DECLARE statement takes this form:

DECLARE [PRIVATE] data-type *variable-list* [HAVING *having-clause*];

Note: A DECLARE statement is allowed only at the top of the programming block in which it is used. Otherwise, a compilation error occurs.

For more information, see "DECLARE Statement" on page 1328.

Variable Declaration Strict Mode

A best practice is to always run your DS2 programs using variable declaration strict mode. This enforces the explicit declaration of all program variables.

For more information about controlling variable declaration strict mode, see "DS2SCOND= System Option" on page 1468.

DECLARE Statement and Scope

When you use a DECLARE statement to define a variable, the variable assumes the scope of the programming block in which the variable is declared. A method is a

subblock of another programming block. Therefore, a variable that is declared in a method has local scope and exists only when the method executes. A variable that is declared outside a method has global scope within that programming block.

For a sample program that demonstrates scope, see "Example: Block Scope" on page 42.

Declaring a Package Instance

Although a package instance is simply a type of variable, it is a special case that is worth mentioning because it has two parts:

package variable
: a variable whose data type is a reference to a type of package.

package instance
: an instance of a type of package. Ideally, a package instance is always referenced by at least one package variable.

> **TIP** The scope of the package variable is determined by the programming block in which it is declared. A package instance does not have an associated scope, and its lifetime depends on the package variables that reference it.

For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

DS2 Methods and Packages

Methods and packages are explained in greater detail in Chapter 5, "Understanding DS2 Methods and Packages," on page 47.

Parallel Processing in DS2

DS2 supports parallel execution of a single program that can operate on different parts of a table. This type of parallelism is classified as Single Program, Multiple Data (SPMD) parallelism. In DS2, it is the responsibility of the programmer to identify the program statements that can operate in parallel.

> **TIP** For programs that are CPU bound, using a thread program on Symmetric Multiprocessing (SMP) hardware can improve performance. For programs that are either CPU or I/O bound, Massively Parallel Processing (MPP) hardware can improve performance.

For more information, see "Threaded Processing" in *SAS DS2 Programmer's Guide*.

For a sample program that demonstrates a simple use of threads, see "Example: A Simple Thread Program" on page 44.

What Is a DS2 Program?

For the purposes of getting started with DS2, a DS2 program is a set of DS2 statements that runs in the DS2 procedure. The getting started sample programs demonstrate that a DS2 program can serve many purposes, including but not limited to the following:

- to define and store one or more packages or threads, in permanent or temporary locations.
- to create one or more data sets or tables, in permanent or temporary locations.
- to run one or more data programs, using any, all, or none of the above components.
- any combination of the above. That is, you can create data, packages, and threads, plus run one or more data programs within a single DS2 program.

The order and number of programming blocks in a DS2 program does not matter, as long as the program compiles and contains enough RUN statements to execute the program.

> **TIP** Always check the log for compilation errors.

In addition, in a SAS session, you can alternate between the DS2 procedure and the SAS DATA step to test your code and to achieve your programming goals.

Example: Block Scope

The following program demonstrates how scope determines the visibility of program identifiers.

What to Notice

- This program has six INTEGER variables that have the name `i`.
- This program has three user-defined methods named SHOWME( ).

```
options ds2scond=error;
proc ds2;
/* INNERPKG */
package innerPkg /overwrite=yes;
  dcl int i;   /* i is global in this package */
  dcl varchar(100) str;

  /* init() - initializes package variables */
  method init();
    i = 5;     /* global i */
    str = 'I am INNERPKG!';
  end;

  /* showMe() - displays values that INNERPKG can "see" */
  method showMe() returns int;
    dcl int i; /* local i */
    i = 10;    /* local i */
    put str;
    put 'Local i=' i;
    put 'Global i=' this.i;
    return 1;
  end;
endpackage;
run;

/* OUTERPKG */
package outerPkg /overwrite=yes;
  dcl int i; /* i is global in this package */
  dcl package innerPkg ip();
  dcl varchar(100) str;

  /* init() - initializes package variables */
  method init();
    i = 15;     /* global i */
    str = 'I am OUTERPKG!';
    ip.init();    /* tell INNERPKG to initialize itself */
  end;

  /* showMe() - displays values that OUTERPKG can "see" */
  method showMe();
    dcl int i; /* local i */
    i = 20; /* local i */
    put str;
    put 'Local i=' i; /* local i */
    put 'Global i=' this.i; /* global i */
    ip.showMe(); /* tell INNERPKG to show what it can "see" */
  end;
endpackage;
run;

/* data program */
data _null_;
  dcl int i; /* i is global in this data program */
  dcl package outerPkg op(); /* instantiate with default constructor */
  dcl varchar(100) str;
  FORWARD showMe;
```

```
  /* init() - automatically runs as the first method in the program */
  method init();
    dcl int rc;
    i = 25;        /* global i */
    str = 'I am the data program!';
    op.init();     /* tell OUTERPKG to initialize itself */
    showMe();      /* show what the data program can "see" */
  end;

  /* showMe() - displays values that the data program can "see" */
  method showMe();
    dcl int i;     /* local i */
    i = 30;        /* local i */
    put str;
    put 'Local i=' i;       /* local i */
    put 'Global i=' this.i; /* global i */
    op.showMe();   /* tell OUTERPKG instance to show what it can "see" */
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
I am the data program!
Local i= 30
Global i= 25
I am OUTERPKG!
Local i= 20
Global i= 15
I am INNERPKG!
Local i= 10
Global i= 5
```

Example: A Simple Thread Program

The following program demonstrates how a thread creates data and passes variables to the data program.

What to Notice

- The parameterized thread accepts a value that must be initialized by the data program using the SETPARMS( ) system method.
- The OVERWRITE=YES table option enables the thread program to be overwritten.

  Note: The THREAD statement syntax requires the '/' (slash character) syntax.
- Because the data program specifies two threads, the thread program runs in two separate threads in a single process.

What to Notice

Note: This thread program produces one set of output variables per thread.

- Because threads run asynchronously, the order of processing is unpredictable, as the log shows.
- In the data program, the global accumulator variable TOTAL is implicitly retained because of the `total+answer;` Sum statement syntax.

```
options DS2SCOND=ERROR;
proc ds2;
/* thread program - Creates data in a loop */
thread work.t (double d) /overwrite=yes;
  dcl int x;
  dcl double y;

  method init();
    dcl int i; /* local - not included in the output table */

    do i = 1 to 9;
      x = i;
      y = i * 2.5 + d;
      put 'THREAD: i=' i ' x= ' x ' y= ' y;
      output; /* output variables include X and Y */
    end;
  end;

  method term();
    put 'THREAD TERM (_ALL_):';
    put _all_;
  end;
endthread;
run;

/* data program - Reads data from a thread program */
data;
  dcl thread work.t t;
  dcl double answer total;

  method init();
    t.setparms(1.25); /* initialize parameter of thread */
    put 'INIT (_ALL_):';
    put _all_;
  end;

  method run();
    set from t threads=2; /* input variables include X and Y */
    answer = x + y;
    total+answer; /* Sum statement syntax implicitly retains TOTAL */
    put ' x= ' x ' y= ' y ' answer= ' answer ' total= ' total;
  end;

  method term();
    put 'TERM: (_ALL_)';
    put _all_;
```

```
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
INIT (_ALL_):
total=0 answer=. x= y=. _N_=1
THREAD: i= 1  x=  1  y=  3.75
THREAD: i= 1  x=  1  y=  3.75
THREAD: i= 2  x=  2  y=  6.25
THREAD: i= 3  x=  3  y=  8.75
THREAD: i= 4  x=  4  y=  11.25
THREAD: i= 5  x=  5  y=  13.75
THREAD: i= 6  x=  6  y=  16.25
THREAD: i= 7  x=  7  y=  18.75
THREAD: i= 8  x=  8  y=  21.25
THREAD: i= 2  x=  2  y=  6.25
THREAD: i= 9  x=  9  y=  23.75
THREAD: i= 3  x=  3  y=  8.75
THREAD TERM (_ALL_):
THREAD: i= 4  x=  4  y=  11.25
d=1.25 x= y=. _N_=1
THREAD: i= 5  x=  5  y=  13.75
THREAD: i= 6  x=  6  y=  16.25
 x=  1  y=  3.75  answer=  4.75  total=  4.75
THREAD: i= 7  x=  7  y=  18.75
THREAD: i= 8  x=  8  y=  21.25
THREAD: i= 9  x=  9  y=  23.75
THREAD TERM (_ALL_):
d=1.25 x= y=. _N_=1
 x=  2  y=  6.25  answer=  8.25  total=  13
 x=  3  y=  8.75  answer=  11.75  total=  24.75
 x=  4  y=  11.25  answer=  15.25  total=  40
 x=  5  y=  13.75  answer=  18.75  total=  58.75
 x=  6  y=  16.25  answer=  22.25  total=  81
 x=  7  y=  18.75  answer=  25.75  total=  106.75
 x=  8  y=  21.25  answer=  29.25  total=  136
 x=  9  y=  23.75  answer=  32.75  total=  168.75
 x=  1  y=  3.75  answer=  4.75  total=  173.5
 x=  2  y=  6.25  answer=  8.25  total=  181.75
 x=  3  y=  8.75  answer=  11.75  total=  193.5
 x=  4  y=  11.25  answer=  15.25  total=  208.75
 x=  5  y=  13.75  answer=  18.75  total=  227.5
 x=  6  y=  16.25  answer=  22.25  total=  249.75
 x=  7  y=  18.75  answer=  25.75  total=  275.5
 x=  8  y=  21.25  answer=  29.25  total=  304.75
 x=  9  y=  23.75  answer=  32.75  total=  337.5

Understanding DS2 Methods and Packages

Modularity, Encapsulation, and Abstraction in DS2

When you use DS2 methods and packages, you approach writing SAS programs differently than you do when programming in DATA step. These DS2 language constructs follow a more structured-programming and object-oriented approach.

In general, DS2 methods are like functions, procedures, subroutines, and the methods of object-oriented languages such as Java. A *method* can be thought of as a module that contains a sequence of instructions to perform a specific task. DS2 methods can exist only within a data program, thread program, or package.

Thus, methods enable you to break up a complex problem into smaller modules. Such modules are easier to design, implement, and test. Code reuse can shorten development time and help standardize often-repeated or business-specific programming tasks. Also, modular programming enhances readability and understandability by testers and other programmers.

DS2 packages enable encapsulation and abstraction of behavior. DS2 packages are similar to classes in object-oriented languages. However, a DS2 package can also be used as a bucket of useful but unrelated methods and variables, if that meets your needs.

A DS2 package bundles data and methods into a named object that can be stored and reused by other DS2 programs. In such a package, the methods defined within the object enable controlled manipulation of package data. Packages and their components are public by default, although a PRIVATE access modifier can be defined to hide all or parts of a package from other programs.

Getting Started with DS2 Methods

What Are DS2 Methods?

Because executable code can reside only in methods, methods are the structural building blocks of DS2 programs.

There are two types of methods:

System Methods
: Also known as predefined, these methods provide the structural and functional framework for your program to execute.

User-Defined Methods
: Similar to functions, procedures, and subroutines in other languages, these are the methods that you create or that someone else created for reuse.

All methods are subblocks of other programming blocks. Each method creates a method scope in which local variables can be defined.

A method programming block begins with the METHOD keyword and ends with the END keyword, as the following example shows.

```
method foo();
...DS2 variables and statements...
end;
```

For more information, see “Methods” in *SAS DS2 Programmer’s Guide*.

What Are DS2 System Methods?

System methods provide the structural framework that runs your code. That is, to create a program, simply add DS2 statements to one or more of these system methods: INIT( ), RUN( ), TERM( ).

System methods also provide special functionality that SAS programmers need and expect for their data and thread programs, such as implicit looping. In addition, system methods enable the semantic grouping of code, which helps make DS2 programs easier to organize, understand, and maintain.

Here are basic facts about system methods:

- Every DS2 program contains—and executes—all three of the main system methods. If you do not explicitly code a system method, the system executes a default version.
- You can explicitly code any, all, or none of the system methods.

  Note: A program that contains no system methods is syntactically correct, but performs no useful function.

- You cannot change the signature of a system method, and you cannot overload a system method.
- You cannot directly call a system method, with the exception of SETPARMS( ), which applies only to thread programs.

For more information, see "Overview of System Methods" on page 1457.

The following table summarizes the execution details of each DS2 system method.

Table 5.1 *DS2 System Methods: Execution Details*

System Method	Execution Details
INIT( )	Automatically executes one time, as the first method of a program. For more information, see "INIT Method" on page 1459.
RUN( )	Automatically executes after INIT( ) completes. The RUN( ) method is the functional equivalent of the DATA step, running as an implicit loop if the method contains a SET or SET FROM statement. For more information, see "RUN Method" on page 1460.
TERM( )	Automatically executes one time, as the last method of a program. For more information, see "TERM Method" on page 1464.
SETPARMS( )	Executes one time, when called from a data program, to initialize the values of a parameterized thread. For more information, see "SETPARMS Method" on page 1462.

What Are DS2 User-Defined Methods?

Similar to functions, procedures, and subroutines in other languages, these are the methods that you create or that someone else created for reuse. Because methods are subblocks of other programming blocks, user-defined methods can exist in data programs, packages, and thread programs.

The following table summarizes basic concepts of user-defined methods.

Table 5.2 *DS2 User-Defined Methods: Basic Concepts*

User-Defined Method Topic	Description
Scope	The name of a user-defined method has global scope within the programming block in which it is defined. In addition, each method creates a method scope in which local variables can be defined. **Note:** You can call a user-defined method from wherever the method is in scope, and you can do it as many times as needed.
Method parameters	A user-defined method can accept arguments in the following ways: ■ by value. The argument value is copied to the method. ■ by reference (IN_OUT parameter). The method modifies the value of the argument variable. **TIP** DS2 methods can support thousands of arguments. The number of arguments supported with a DS2 method varies, depending on the data type of the arguments and the system in which the DS2 program is run. A DS2 method that exceeds the number of supported arguments generates a compilation error.
Return values	Like a function, a user-defined method can return a value.
Method overloading	User-defined methods that have the same name can exist in the same scope if their argument signatures are unique. That is, if only the return type differs, then the overloading is ambiguous. The following examples show an overloaded method with three unique argument signatures: `method squareIt(int value) returns int;` `  return value**2;` `end;` `method squareIt(decimal(6,2) value) returns decimal(8,4);` `  return value**2;` `end;` `method squareIt(int value, IN_OUT int square);`

User-Defined Method Topic	Description
	square = value**2; end;
Calling	Unlike system methods, which automatically run, user-defined methods must be called. You can call a user-defined method as many times as needed.

For more information, see "METHOD Statement" on page 1391.

Getting Started with DS2 Packages

What Are DS2 Packages?

DS2 packages are language constructs that bundle variables and methods into named objects that can be stored and reused by other DS2 programs. The main benefit of a package derives from the reusability of a set of useful methods. However, DS2 packages are capable of much more.

A DS2 package is similar to a class in object-oriented languages. Thus, you can write packages that approximate the encapsulation and abstraction of object-oriented classes.

Note: A DS2 package is not a program. A DS2 package is a template for instantiating an object that can be used in a program.

There are two types of packages:

Predefined packages
: These packages encapsulate common functionality that is useful to many customer solutions (for example, manipulating hash and matrix data structures). Predefined packages are part of DS2.

User-defined packages
: These are the packages that you create or that someone else created for reuse.

A package is defined by a package programming block. A package begins with the PACKAGE keyword and ends with the ENDPACKAGE keyword, as the following example shows.

```
package foo;
  ...DS2 variables, statements, and methods...
endpackage;
```

The following table summarizes basic concepts of both user-defined and predefined packages.

Table 5.3 *DS2 Packages: Basic Concepts*

Package Topic	Description
Scope	Every package defines its own scope. The names of methods and global variables declared within the body of the package are in the scope of the package. Package methods and attributes may be accessed by name without any other qualification from other methods in the same package scope. In methods outside the scope of the package, package methods and attributes can be accessed only using dot notation.
Package methods	To execute a package method, your program must call it with a package instance. The package instance can either be explicitly specified using dot notation or be the implicit THIS argument of a previous package method call. For example: `proc ds2;` `package mypackage / inline;` `  method a(int x);` `  put 'method called with' x=;` `  end;` `  method b(int x);` `  a(x);  /* 1 */` `  end;` `endpackage;` `data _null_;` `  method init();` `  declare package mypackage p();` `  p.b(20);  /* 2 */` `  end;` `enddata;` `run;` `quit;` 1 Method b calls method a with the same implicit THIS argument with which method b was called. 2 Method INIT calls method b with the package instance referenced by package variable p. Nested dot notation is supported to enable you to access package attributes and invoke package methods from within a hierarchy of packages.
Preparing packages for use	A package must be defined before it can be used in a program. You can use the DS2 procedure to define and store a user-defined package. For more information, see “PACKAGE Statement” on page 1406.
Overwriting packages	Unlike DATA step, DS2 protects existing tables from being overwritten. However, if you are developing or changing a package, you need the ability to overwrite the package. To overwrite an existing package, use the OVERWRITE=YES table option, as the following example shows.

Package Topic	Description
	`` package greeting /overwrite=yes; ...DS2 variables, statements, and methods... endpackage; run; ```
Instantiating packages	To use a package, you create an instance of the package (a package instance) and a variable that references the instance (a package variable). You can instantiate a package in two ways: ■ The DECLARE PACKAGE statement can simultaneously declare one or more package variables. For each declared package variable, the DECLARE PACKAGE statement can optionally construct a package instance. For example: ``` dcl package matrix m0 m1(3, 3) m2(5, 4); ``` The above statement declares three matrix package variables (m0, m1, and m2) and constructs two matrix package instances (one of which is assigned to m1 and one of which is assigned to m2). ■ You can use the DECLARE PACKAGE statement to declare the package variable (omitting constructor arguments), then assign a package instance using the _NEW_ operator: ``` data _null_; dcl package matrix m1 m2; method init(); dcl package matrix m3; m1 = _NEW_ matrix(3, 2); m3 = _NEW_ matrix(5, 4); m2 = _NEW_ matrix(); end; ...DS2 methods... enddata; run; ``` These statements also create and instantiate three package variables for package matrix. However, the _NEW_ operator constructs the package instances and assigns them to the package variables. **Note:** If you declare a package variable without simultaneously declaring an instance of the package, the value of the package variable is NULL. **Note:** DS2 supports array package variables. An array package variable enables you to reference multiple package instances from a single variable. For more information, see DECLARE PACKAGE statement.

For more information, see "DS2 Packages" in *SAS DS2 Programmer's Guide*.

What Are DS2 Predefined Packages?

Predefined packages encapsulate common functionality that is useful to many customer solutions.

For a list of the predefined packages that are available with DS2, see "Predefined DS2 Packages" in *SAS DS2 Programmer's Guide*.

You can find many example programs that use predefined packages in Appendix 3, "DS2 Example Programs," on page 2177.

Example: Introduction to DS2 Methods

The following program demonstrates many characteristics of both system and user-defined DS2 methods.

What to Notice

- This program has three overloaded user-defined methods named SQUAREIT( ).
- This program contains three system methods.

```
options DS2SCOND=ERROR;
proc ds2;
/* data program */
data _null_;
  dcl int root1 result1;
  dcl decimal(6,2) root2;
  dcl decimal(8,4) result2;

  /* overloaded user-defined method */
  method squareIt(int value) returns int;
    return value**2;
  end;

  /* overloaded user-defined method */
  method squareIt(decimal(6,2) value) returns decimal(8,4);
    return value**2;
  end;

  /* overloaded user-defined method with IN_OUT parameter */
  method squareIt(int value, IN_OUT int square);
    square = value**2;
  end;
```

```
  /* system method */
  method init();
    root1 = 3.01;
    root2 = 3.01;
  end;

  /* system method */
  method run();
    result1 = squareIt(root1);
    put 'The square of INTEGER ' root1 ' is ' result1;

    result2 = squareIt(root2);
    put 'The square of DECIMAL ' root2 ' is ' result2;

    root1 = 4.99;
    squareIt(root1, result1);
    put 'The square of INTEGER ' root1 ' is ' result1;
  end;

  /* system method */
  method term();
    put _all_; /* final values of global variables */
  end;
enddata;
run; quit;
```

The following is written to the log:

```
The square of INTEGER  3  is  9
The square of DECIMAL  3.01  is  9.0601
The square of INTEGER  4  is  16
root1= root2= result1= result2= _N_=1
```

Example: Introduction to DS2 Packages

The following program demonstrates some basic concepts of packages. This is a version of the “Hello World!” program that uses a package to write messages to the SAS log.

What to Notice

- The PACKAGE statement uses the OVERWRITE=YES table option so that you can run the program more than once without error. By default, DS2 protects existing packages from being overwritten.
- In the data program, the DECLARE PACKAGE statement simultaneously declares package variables and constructs two separate instances of the package using the package constructor.

What to Notice

- Dot notation provides access to package methods and package-global variables from the data program.

  Note: Although this sample program shows that you can directly access package-global variables, the recommended best practice is to avoid this practice unless you have a valid reason to do so. This best practice is a form of data encapsulation, which is a common programming technique in object-oriented programming.

```
options DS2SCOND=ERROR;
proc ds2;
/* GREETING - User-defined package that writes a message to the SAS log */
package greeting /overwrite=yes;
  dcl varchar(100) message;    /* Global scope package attribute */

  /* greeting(MESSAGE) - constructor that accepts an argument */
  method greeting(varchar(100) message);
    THIS.message = message;
  end;

  /* greeting() - default constructor */
  method greeting();
  end;

  /* package method */
  method greet();
    if not missing(message) then
      put message;
    else put 'Message is null or missing.';
  end;
endpackage;
run;

/* data program */
data _null_;
  /* declares and instantiates two instances of the GREETING package */
  dcl package greeting g1('Hello World!') g2();  /* data program (global) scope */

  /* init() - system method */
  method init();
    g1.greet();
    g2.greet();
    g2.message = 'Good-bye World!';
    g2.greet();
  end;
enddata;
run;
quit;
```

The following is written to the log:

```
Hello World!
Message is null or missing.
Good-bye World!
```

PART 3

DS2 Language Reference

6

DS2 Formats

Overview of Formats

A **format** is an instruction that DS2 uses to write data values. Formats are used to control the written appearance of the data values. For example, the ROMAN*w*. format, which converts numeric values to roman numerals, writes the numeric value 2006 as `MMVI`. Formats can also be used to group data values together for analysis.

General Format Syntax

DS2 formats have the following form:

[$] *format* [*w*] . [*d*]

Here is an explanation of the syntax:

$
indicates a character format; its absence indicates a numeric format.

format
names the format. The format is a DS2 format or a user-defined format that was previously defined with the INVALUE statement in PROC FORMAT. For more information about user-defined formats, see the *Base SAS Procedures Guide*.

Restriction To create and access user-defined formats, a SAS session must be available in order to access the SAS catalog file that stores the SAS format definitions.

w
specifies the format width, which for most formats is the number of characters in the input data.

d
specifies an optional decimal scaling factor in the numeric formats. DS2 divides the input data by 10 to the power of *d*.

Tip When the value of *d* is greater than 15, the precision of the decimal value after the 15th decimal place might not be accurate.

Formats always contain a period (.) as a part of the name. If you omit the *w* and the *d* values from the format, DS2 uses default values. The *d* value that you specify with a format tells DS2 to display that many decimal places, regardless of how many decimal places are in the data. Formats never change or truncate the internally stored data values.

For example, in DOLLAR10.2, the *w* value of 10 specifies a maximum of 10 characters for the value. The *d* value of 2 specifies that two of these characters are for the decimal part of the value, which leaves eight characters for all the remaining characters in the value. This includes the decimal point, the remaining numeric value, a minus sign if the value is negative, the dollar sign, and commas, if any.

If the format width is too narrow to represent a value, DS2 tries to squeeze the value into the space available. Character formats truncate values on the right. Numeric formats sometimes revert to the BEST*w.d* format. DS2 prints asterisks if you do not specify an adequate width. In the following example, the result is x=**.

```
x=123;
put x= 2.;
```

If you use an incompatible format, such as using a numeric format to write character values, DS2 first attempts to use an analogous format of the other type. If this is not feasible, an error message that describes the problem appears in the SAS log.

Using Formats in DS2

How to Specify Formats

In DS2, specify formats as an attribute of the HAVING clause of the DECLARE statement. The HAVING clause provides equivalent functionality to the DATA step FORMAT and LABEL statements, except that now the attribute must be specified in the declaration statement of the variable.

For example, in the following statement, the columns *profit* and *loss* are declared with the EURO13.2 format.

```
dcl double profit loss having format euro13.2;
```

Note: In DS2, a format that is defined on a column with the HAVING clause cannot be changed or removed. However, you can use formats as arguments in the PUT function to write data in a different format. For more information, see "Write Formatted Data in DS2" on page 65.

Write Formatted Data in DS2

You can use formats as arguments in the PUT function to write formatted data. If a value is not specified for the format width or decimal specification, DS2 uses the default values for that format. Note that when using input-width aware formats such as $OCTAL and $HEX, the width, decimal specification, or both is calculated from the input field width. For example, $HEX uses 2 times the width and $OCTAL uses 3 times the width.

For example, in this case, the PUT function returns the formatted value of 99 using the BEST12. format.

```
x=99;
y=put(x, best12.);
```

If the PUT function is used without a format, all data is written without formatting.

Any type conversions of the value that is formatted are done based on the format name. Any value that is passed to the PUT function with a numeric format is converted, if necessary, to DOUBLE. Any value that is passed to the PUT function with a character format is converted to NCHAR. For more information, see the "PUT Function" on page 1051.

DS2 supports SAS formats as follows.

- Formats that are supplied by SAS and user-defined formats can be used. For information about how to create your own format in SAS, see PROC FORMAT in the *Base SAS Procedures Guide*.

  Note: To create and access user-defined formats, a SAS session must be available in order to access the SAS catalog file that stores the SAS format definitions.

- Only SAS data sets, SPD engine data sets, and SPD Server tables support storing and retrieving a format with a column.
- Formats can be associated with all data types, but all data types are converted to either CHAR or DOUBLE.
- You associate SAS formats with a column by using the HAVING clause of the DS2 DECLARE statement. For more information, see "How to Specify Formats" on page 64.

Validation of DS2 Formats

Formats are not validated by a data source or applied to a column until execution time.

When metadata for a column is requested, the format name is returned without validation.

DS2 Format Examples

```
declare datetime shipdate having format dateampm22.2;
x = put (name, $char8.);
x = put (price, myformat. -c);
```

Format Categories

Formats can be categorized by the types of values that they operate on. Each DS2 format belongs to one of the following categories:

Table 6.1 *Format Category Descriptions*

Category	Description
Character	writes character data values from character variables. See Character for a list of formats.
Date and Time	writes character data values from character variables. See Date and Time for a list of formats.
Numeric	writes numeric data values from numeric variables. See Numeric for a list of formats.

The following table provides brief descriptions of DS2 formats. For more detailed information, see the individual formats.

Category	Language Elements	Description
Character	$BASE64Xw. Format (p. 73)	Converts character data into ASCII text by using Base 64 encoding.
	$BINARYw. Format (p. 75)	Converts character data to binary representation.
	$CHARw. Format (p. 76)	Writes standard character data.
	$HEXw. Format (p. 77)	Converts character data to hexadecimal representation.
	$OCTALw. Format (p. 78)	Converts character data to octal representation.
	$QUOTEw. Format (p. 80)	Writes data values that are enclosed in double quotation marks.
	$REVERJw. Format (p. 82)	Writes character data in reverse order and preserves blanks.
	$REVERSw. Format (p. 83)	Writes character data in reverse order and left aligns.
	$UPCASEw. Format (p. 84)	Converts character data to uppercase.
	$UUIDw. Format (p. 85)	Writes character data in universally unique identifier (UUID) format.
	$w. Format (p. 86)	Writes standard character data.
Date and Time	B8601DAw. Format (p. 87)	Writes date values by using the ISO 8601 basic notation yyyymmdd.
	B8601DNw. Format (p. 89)	Writes dates from datetime values by using the ISO 8601 basic notation yyyymmdd.
	B8601DTw.d Format (p. 90)	Writes datetime values by using the ISO 8601 basic notation yyyymmddThhmmss<ffffff>.
	B8601DZw. Format (p. 92)	Writes datetime values for the zero meridian Coordinated Universal Time (UTC) time by using the ISO 8601 datetime and time zone basic notation yyyymmddThhmmss+0000.
	B8601LZw. Format (p. 94)	Writes time values as local time by appending a time zone offset difference between the local time and UTC, using the ISO 8601 basic time notation hhmmss+|–hhmm.
	B8601TMw.d Format (p. 96)	Writes time values by using the ISO 8601 basic notation hhmmss<ffff>.
	B8601TZw. Format (p. 98)	Adjusts time values to the Coordinated Universal Time (UTC) and writes the time values by using the ISO 8601 basic time notation hhmmss+|–hhmm.
	DATEw. Format (p. 112)	Writes SAS date values in the form ddmmmyy, ddmmmyyyy, or dd-mmm-yyyy.
	DATEAMPMw.d Format (p. 114)	Writes SAS datetime values in the form ddmmmyy:hh:mm:ss.ss with AM or PM.

Category	Language Elements	Description
	DATETIMEw.d Format (p. 116)	Writes SAS datetime values in the form ddmmmyy:hh:mm:ss.ss.
	DAYw. Format (p. 118)	Writes SAS date values as the day of the month.
	DDMMYYw. Format (p. 119)	Writes SAS date values in the form ddmm<yy>yy or dd/mm/<yy>yy, where a forward slash is the separator and the year appears as either 2 or 4 digits.
	DDMMYYxw. Format (p. 121)	Writes SAS date values in the form ddmm<yy>yy or dd-mm-yy<yy>, where x in the format name is a character that represents the special character that separates the day, month, and year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.
	DOWNAMEw. Format (p. 127)	Writes SAS date values as the name of the day of the week.
	DTDATEw. Format (p. 128)	Expects a SAS datetime value as input and writes the SAS date values in the form ddmmmyy or ddmmmyyyy.
	DTMONYYw. Format (p. 130)	Writes the date part of a SAS datetime value as the month and year in the form mmmyy or mmmyyyy.
	DTWKDATXw. Format (p. 132)	Writes the date part of a SAS datetime value as the day of the week and the date in the form day-of-week, dd month-name yy (or yyyy).
	DTYEARw. Format (p. 134)	Writes the date part of a SAS datetime value as the year in the form yy or yyyy.
	DTYYQCw. Format (p. 135)	Writes the date part of a SAS datetime value as the year and the quarter and separates them with a colon (:).
	E8601DAw. Format (p. 136)	Writes date values by using the ISO 8601 extended notation yyyy-mm-dd.
	E8601DNw. Format (p. 138)	Writes dates from SAS datetime values by using the ISO 8601 extended notation yyyy-mm-dd.
	E8601DTw.d Format (p. 139)	Writes datetime values by using the ISO 8601 extended notation yyyy-mm-ddThh:mm:ss.ffffff.
	E8601DZw. Format (p. 141)	Writes datetime values for the zero meridian Coordinated Universal Time (UTC) time by using the ISO 8601 datetime and time zone extended notation yyyy-mm-ddThh:mm:ss +00:00.
	E8601LZw. Format (p. 143)	Writes time values as local time, appending the Coordinated Universal Time (UTC) offset for the local SAS session, using the ISO 8601 extended time notation hh:mm:ss+|–hh:mm.

Category	Language Elements	Description
	E8601TMw.d Format (p. 146)	Writes time values by using the ISO 8601 extended notation hh:mm:ss.ffffff.
	E8601TZw.d Format (p. 147)	Adjusts time values to the Coordinated Universal Time (UTC) and writes the time values by using the ISO 8601 extended notation hh:mm:ss.<fff>+|−hh:mm.
	HHMMw.d Format (p. 158)	Writes SAS time values as hours and minutes in the form hh:mm.
	HOURw.d Format (p. 161)	Writes SAS time values as hours and decimal fractions of hours.
	JULIANw. Format (p. 164)	Writes SAS date values as Julian dates in the form yyddd or yyyyddd.
	MDYAMPMw.d Format (p. 166)	Writes datetime values in the form mm/dd/yy<yy> hh:mm AM|PM. The year can be either two or four digits.
	MMDDYYw. Format (p. 168)	Writes SAS date values in the form mmdd<yy>yy or mm/dd/<yy>yy, where a forward slash is the separator and the year appears as either 2 or 4 digits.
	MMDDYYxw. Format (p. 170)	Writes SAS date values in the form mmdd<yy>yy or mm-dd-<yy>yy, where the x in the format name is a character that represents the special character, which separates the month, day, and year. The special character can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.
	MMSSw.d Format (p. 172)	Writes SAS time values as the number of minutes and seconds since midnight.
	MMYYw. Format (p. 174)	Writes SAS date values in the form mmM<yy>yy, where M is the separator and the year appears as either 2 or 4 digits.
	MMYYxw. Format (p. 175)	Writes SAS date values in the form mm<yy>yy or mm-<yy>yy, where the x in the format name is a character that represents the special character that separates the month and the year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.
	MONNAMEw. Format (p. 177)	Writes SAS date values as the name of the month.
	MONTHw. Format (p. 179)	Writes SAS date values as the month of the year.
	MONYYw. Format (p. 180)	Writes SAS date values as the month and the year in the form mmmyy or mmmyyyy.
	NENGOw. Format (p. 183)	Writes SAS date values as Japanese dates in the form e.yymmdd.
	QTRw. Format (p. 189)	Writes SAS date values as the quarter of the year.

Category	Language Elements	Description
	QTRRw. Format (p. 191)	Writes SAS date values as the quarter of the year in Roman numerals.
	TIMEw.d Format (p. 193)	Writes SAS time values as hours, minutes, and seconds in the form hh:mm:ss.ss.
	TIMEAMPMw.d Format (p. 195)	Writes SAS time values as hours, minutes, and seconds in the form hh:mm:ss.ss with AM or PM.
	TODw.d Format (p. 197)	Writes SAS time values and the time portion of SAS datetime values in the form hh:mm:ss.ss.
	WEEKDATEw. Format (p. 203)	Writes SAS date values as the day of the week and the date in the form day-of-week, month-name dd, yy (or yyyy).
	WEEKDATXw. Format (p. 205)	Writes SAS date values as the day of the week and date in the form day-of-week, dd month-name yy (or yyyy).
	WEEKDAYw. Format (p. 207)	Writes SAS date values as the day of the week.
	YEARw. Format (p. 208)	Writes SAS date values as the year.
	YYMMw. Format (p. 211)	Writes SAS date values in the form <yy>yyMmm, where M is a character separator to indicate that the month number follows the M and the year appears as either 2 or 4 digits.
	YYMMxw. Format (p. 213)	Writes SAS date values in the form <yy>yymm or <yy>yy-mm, where the x in the format name is a character that represents the special character that separates the year and the month, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.
	YYMMDDw. Format (p. 215)	Writes SAS date values in the form <yy>yymmdd or <yy>yy–mm–dd, where a hyphen is the separator and the year appears as either 2 or 4 digits.
	YYMMDDxw. Format (p. 217)	Writes SAS date values in the form <yy>yymmdd or <yy>yy-mm-dd, where the x in the format name is a character that represents the special character that separates the year, month, and day. The special character can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.
	YYMONw. Format (p. 219)	Writes SAS date values in the form yymmm or yyyymmm.
	YYQw. Format (p. 221)	Writes SAS date values in the form <yy>yyQq, where Q is the separator, the year appears as either 2 or 4 digits, and q is the quarter of the year.
	YYQxw. Format (p. 223)	Writes SAS date values in the form <yy>yyq or <yy>yy-q, where the x in the format name is a character that represents the special character that separates the year and the quarter of the year, which can be a hyphen (–),

Category	Language Elements	Description
		period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.
	YYQRw. Format (p. 225)	Writes SAS date values in the form <yy>yyQqr, where Q is the separator, the year appears as either 2 or 4 digits, and qr is the quarter of the year expressed in roman numerals.
	YYQRxw. Format (p. 227)	Writes SAS date values in the form <yy>yyqr or <yy>yy-qr, where the x in the format name is a character that represents the special character that separates the year and the quarter of the year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits and qr is the quarter of the year expressed in roman numerals.
	YYQZw. Format (p. 229)	Writes SAS date values in the form <yy><qq>, the year appears as 2 or 4 digits, and qq is the quarter of the year.
ISO 8601	B8601DAw. Format (p. 87)	Writes date values by using the ISO 8601 basic notation yyyymmdd.
	B8601DNw. Format (p. 89)	Writes dates from datetime values by using the ISO 8601 basic notation yyyymmdd.
	B8601DTw.d Format (p. 90)	Writes datetime values by using the ISO 8601 basic notation yyyymmddThhmmss<ffffff>.
	B8601DZw. Format (p. 92)	Writes datetime values for the zero meridian Coordinated Universal Time (UTC) time by using the ISO 8601 datetime and time zone basic notation yyyymmddThhmmss+0000.
	B8601LZw. Format (p. 94)	Writes time values as local time by appending a time zone offset difference between the local time and UTC, using the ISO 8601 basic time notation hhmmss+|–hhmm.
	B8601TMw.d Format (p. 96)	Writes time values by using the ISO 8601 basic notation hhmmss<ffff>.
	B8601TZw. Format (p. 98)	Adjusts time values to the Coordinated Universal Time (UTC) and writes the time values by using the ISO 8601 basic time notation hhmmss+|–hhmm.
	E8601DAw. Format (p. 136)	Writes date values by using the ISO 8601 extended notation yyyy-mm-dd.
	E8601DNw. Format (p. 138)	Writes dates from SAS datetime values by using the ISO 8601 extended notation yyyy-mm-dd.
	E8601DTw.d Format (p. 139)	Writes datetime values by using the ISO 8601 extended notation yyyy-mm-ddThh:mm:ss.ffffff.
	E8601DZw. Format (p. 141)	Writes datetime values for the zero meridian Coordinated Universal Time (UTC) time by using the ISO 8601 datetime and time zone extended notation yyyy-mm-ddThh:mm:ss +00:00.

Category	Language Elements	Description
	E8601LZw. Format (p. 143)	Writes time values as local time, appending the Coordinated Universal Time (UTC) offset for the local SAS session, using the ISO 8601 extended time notation hh:mm:ss+|−hh:mm.
	E8601TMw.d Format (p. 146)	Writes time values by using the ISO 8601 extended notation hh:mm:ss.ffffff.
	E8601TZw.d Format (p. 147)	Adjusts time values to the Coordinated Universal Time (UTC) and writes the time values by using the ISO 8601 extended notation hh:mm:ss.<fff>+|−hh:mm.
Numeric	BESTw. Format (p. 100)	SAS chooses the best notation.
	BESTDOTXw. Format (p. 102)	Specifies that SAS choose the best notation and use a dot as a decimal separator.
	BESTDw.p Format (p. 103)	Prints numeric values, lining up decimal places for values of similar magnitude, and prints integers without decimals.
	BINARYw. Format (p. 106)	Converts numeric values to binary representation.
	COMMAw.d Format (p. 107)	Writes numeric values with a comma that separates every three digits and a period that separates the decimal fraction.
	COMMAXw.d Format (p. 109)	Writes numeric values with a period that separates every three digits and a comma that separates the decimal fraction.
	Dw.p Format (p. 110)	Prints numeric values, possibly with a great range of values, lining up decimal places for values of similar magnitude.
	DOLLARw.d Format (p. 123)	Writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.
	DOLLARXw.d Format (p. 125)	Writes numeric values with a leading dollar sign, a period that separates every three digits, and a comma that separates the decimal fraction.
	Ew. Format (p. 150)	Writes numeric values in scientific notation.
	EUROw.d Format (p. 151)	Writes numeric values with a leading euro symbol (E), a comma that separates every three digits, and a period that separates the decimal fraction.
	EUROXw.d Format (p. 153)	Writes numeric values with a leading euro symbol (E), a period that separates every three digits, and a comma that separates the decimal fraction.
	FLOATw.d Format (p. 154)	Generates a native single-precision, floating-point value by multiplying a number by 10 raised to the dth power.
	FRACTw. Format (p. 156)	Converts numeric values to fractions.

Category	Language Elements	Description
	HEXw. Format (p. 157)	Converts real binary (floating-point) values to hexadecimal representation.
	IEEEw.d Format (p. 163)	Generates an IEEE floating-point value by multiplying a number by 10 raised to the dth power.
	NEGPARENw.d Format (p. 182)	Writes negative numeric values in parentheses.
	OCTALw. Format (p. 185)	Converts numeric values to octal representation.
	PERCENTw.d Format (p. 186)	Writes numeric values as percentages.
	PERCENTNw.d Format (p. 188)	Produces percentages, using a minus sign for negative values.
	ROMANw. Format (p. 192)	Writes numeric values as roman numerals.
	VAXRBw.d Format (p. 199)	Writes real binary (floating-point) data in VMS format.
	w.d Format (p. 201)	Writes standard numeric data one digit per byte.
	YENw.d Format (p. 209)	Writes numeric values with yen signs, commas, and decimal points.
	Zw.d Format (p. 230)	Writes standard numeric data with leading 0s.

Dictionary

$BASE64Xw. Format

Converts character data into ASCII text by using Base 64 encoding.

Category: Character

Alignment: Left

Syntax

$BASE64X*w*.

Required Argument

w

specifies the width of the output field.

Default 1

Range 1–32767

Note If you specify the $BASE64X. format without a width, it uses a default width of 1, which is insufficient to produce output. No results are returned.

Details

Base 64 is an industry encoding method whose encoded characters are determined by using a positional scheme that uses only ASCII characters. Several Base 64 encoding schemes have been defined by the industry for specific uses, such as email or content masking. SAS maps positions 0 – 61 to the characters A – Z, a – z, and 0 – 9. Position 62 maps to the character +, and position 63 maps to the character /.

Here are some uses of Base 64 encoding:

- embed binary data in an XML file
- encode passwords
- encode URLs

The '=' character in the encoded results indicates that the results have been padded with zero bits. In order for the encoded characters to be decoded, the '=' must be included in the value to be decoded.

Example

The following program illustrates the $BASE64X*w*. format:

```
data _null_;
   declare varchar(30) a b c ;
   method run();
      a= put('FCA01A7993BC', $base64x64.);
      b= put('MyPassword', $base64x64.);
      c= put('www.mydomain.com/myhiddenURL', $base64x64.);
      put a= b= c=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=RkNBMDFBNzk5M0JD              b=TXlQYXNzd29yZA==              c=d3d3Lm15ZG9tYWluLmNvbS9teWhpZ
```

$BINARYw. Format

Converts character data to binary representation.

Category: Character

Alignment: Left

Syntax

$BINARY*w*.

Required Argument

w
specifies the width of the output field.

Default The default width is calculated based on the length of the variable to be printed.

Range 1–32767

Tip Because each character value generates eight binary characters, increase the value of *w* by eight times the length of the character value.

Comparisons

The $BINARY*w*. format converts character values to binary representation. The BINARY*w*. format converts numeric values to binary representation.

Example

The following program illustrates the $BINARY*w*. format:

```
data _null_;
   declare varchar(30) a;
   method run();
      a = put ('name', $binary16.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=0110111001100001
```

See Also

Formats:

- “BINARYw. Format” on page 106

$CHARw. Format

Writes standard character data.

Category: Character

Alignment: Left

Alias: $*w*. and $F*w*.

Syntax

$CHAR*w*.

Required Argument

w

specifies the width of the output field. You can specify a number or a column range.

Default 8 if the length of variable is undefined; otherwise, the length of the variable.

Range 1–32767

Comparisons

- The $CHAR*w*. format is identical to the $*w*. and $F*w*. formats.
- The $CHAR*w*., $F*w*., and $*w*. formats do not trim leading blanks. To trim leading blanks, use the LEFT function to left align character data before output.

Example

The following program illustrates the $CHAR*w*. format:

```
data _null_;
   declare varchar(30) a;
   method run();
      a= put ('XYZ',$char.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=XYZ
```

$HEXw. Format

Converts character data to hexadecimal representation.

Category: Character

Alignment: Left

Syntax

$HEX*w*.

Required Argument

w
specifies the width of the output field.

Default The default width is calculated based on the length of the variable to be printed.

Range 1–32767

Note If *w* is greater than twice the length of the variable that you want to represent, $HEX*w*. pads it with blanks.

Tip Because each character value generates two hexadecimal characters, increase the value of *w* by two times the length of the character value.

Details

The $HEX*w*. format converts each character into two hexadecimal characters. Each blank counts as one character, including trailing blanks.

Comparisons

The HEX*w*. format converts real binary numbers to their hexadecimal equivalent.

Example

The following program illustrates the $HEX*w*. format:

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put ('bank', $hex.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=62616E6B
```

See Also

Formats:

- “HEXw. Format” on page 157

$OCTALw. Format

Converts character data to octal representation.

Category: Character

Alignment: Left

Syntax

$OCTAL*w*.

Required Argument

w
specifies the width of the output field.

Default The default width is calculated based on the length of the variable to be printed.

Range 1–32767

Tip Because each character value generates three octal characters, increase the value of *w* by three times the length of the character value.

Comparisons

The $OCTAL*w*. format converts character values to the octal representation of their character codes. The OCTAL*w*. format converts numeric values to octal representation.

Example

The following program illustrates the $OCTAL*w*. format:

```
data _null_;
   declare varchar(30) a b c;
   method run();
      a=put('art', $octal9.);
      b=put('rice', $octal12.);
      c=put('bank', $octal12.);
      put a= b= c=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=141162164 b=162151143145 c=142141156153
```

See Also

Formats:

- “OCTALw. Format” on page 185

$QUOTEw. Format

Writes data values that are enclosed in double quotation marks.

Category: Character

Alignment: Left

Syntax

$QUOTE*w*.

Required Argument

w

specifies the width of the output field.

Default 2 if the length of the variable is undefined; otherwise, the length of the variable + 2

Range 2–32767

Tip Make *w* wide enough to include the left and right quotation marks.

Details

The following list describes the output that SAS produces when you use the $QUOTE*w*. format.

- When your data value is not enclosed in quotation marks, SAS encloses the output in double quotation marks.
- When your data value is not enclosed in quotation marks, but the value contains a single quotation mark, SAS takes the following action:
  - encloses the data value in double quotation marks
  - does not change the single quotation mark.
- When your data value begins and ends with single quotation marks, and the value contains double quotation marks, SAS takes the following action:
  - encloses the data value in double quotation marks
  - duplicates the double quotation marks that are found in the data value
  - does not change the single quotation marks.

- When your data value begins and ends with single quotation marks, and the value contains two single contiguous quotation marks, SAS takes the following action:
  - encloses the value in double quotation marks
  - does not change the single quotation marks.
- When your data value begins and ends with single quotation marks, and contains both double quotation marks and single, contiguous quotation marks, SAS takes the following action:
  - encloses the value in double quotation marks
  - duplicates the double quotation marks that are found in the data value
  - does not change the single quotation marks.
- When the length of the target field is not large enough to contain the string and its quotation marks, SAS returns as much of the quoted string that fits into the field. For example, if the specified value is ABCDE and you specify $QUOTE5., then DE in the value is truncated and the result is "ABC".

Note: An embedded quotation mark must be enclosed within additional quotation marks. If you specify a value of A"B, then $QUOTE5. truncates the B in the value and writes "A"".

Example

The following program illustrates the $QUOTE*w*. format:

```
data _null_;
   declare varchar(30) a b c d e f;
   method run();
      a=put('SAS',$quote.);
      b=put('SAS''s',$quote.);
      c=put('ad''verb',$quote16.);
      d=put('"ad" "verb"',$quote16.);
      e=put('"ad"''"verb"',$quote20.);
      f=put('deoxyribonucleotide',$quote20.);
      put a= b= c= d= e= f=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a="SAS" b="SAS's" c="ad'verb"        d="""ad"" ""verb"  e="""ad""'""verb""""
f="deoxyribonucleotid"
```

$REVERJw. Format

Writes character data in reverse order and preserves blanks.

Category: Character

Alignment: Right

Syntax

$REVERJ*w*.

Required Argument

w
specifies the width of the output field.

Default 1 if *w* is not specified

Range 1–32767

Comparisons

The $REVERJ*w*. format is similar to the $REVERS*w*. format except that $REVERS*w*. left aligns the result by trimming all leading blanks.

Example

The following program illustrates the $REVERJ*w*. format:

```
data _null_;
   declare varchar(30) a b;
   method run();
      a=put('ABCD###',$reverj7.);
      b=put('###ABCD',$reverj7.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=###DCBA b=DCBA###
```

See Also

Formats:

- “$REVERSw. Format” on page 83

$REVERSw. Format

Writes character data in reverse order and left aligns.

Category: Character

Alignment: Left

Syntax

$REVERS*w*.

Required Argument

w
specifies the width of the output field.

Default 1 if *w* is not specified

Range 1–32767

Comparisons

The $REVERS*w*. format is similar to the $REVERJ*w*. format except that $REVERJ*w*. does not left align the result.

Example

The following program illustrates the $REVERS*w*. format:

```
data _null_;
   declare varchar(30) a b;
   method run();
      a=put('ABCD   ',$revers7.);
      b=put('   ABCD',$revers7.);
      put a= b=;
   end;
enddata;
```

```
run;
```

SAS writes the following output to the log.

```
a=DCBA    b=DCBA
```

See Also

Formats:

- “$REVERJw. Format” on page 82

$UPCASEw. Format

Converts character data to uppercase.

Category: Character

Alignment: Left

Syntax

$UPCASE*w*.

Required Argument

w
specifies the width of the output field.

Default 8 if the length of the variable is undefined; otherwise, the length of the variable.

Range 1–32767

Details

Special characters, such as hyphens and other symbols, are not altered.

Example

The following program illustrates the $UPCASE*w*. format:

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put('coxe-ryan',$upcase9.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=COXE-RYAN
```

$UUIDw. Format

Writes character data in universally unique identifier (UUID) format.

Category: Character

Alignment: Left

Syntax

$UUID*w*.

Required Argument

w
specifies the width of the output field.

Range 1–200

Details

You must provide the value that you want in hexadecimal format. Otherwise, the hexadecimal representation of the original characters is returned as the UUID.

Note: If you provide the value as a hexadecimal literal with an 'x' at the beginning, the value can be enclosed only in single quotation marks. You cannot use double quotation marks.

Example

The following program illustrates the $UUID*w*. format:

```
data _null_;
   declare char(36) x y;
   method run();
      x=put (x'1548611fb8cb6a47a721a6fd284e74f2', $uuid36.);
      put x=;
      x = inputc('1548611f-b8cb-6a47-a721-a6fd284e74f2','$uuid36.');
      y=put (x, $uuid36.);
      put y=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
x=1548611f-b8cb-6a47-a721-a6fd284e74f2
y=1548611f-b8cb-6a47-a721-a6fd284e74f2
```

$w. Format

Writes standard character data.

Category: Character

Alignment: Left

Alias: $F*w*. and $CHAR*w*.

Syntax

$*w*.

Required Argument

w

specifies the width of the output field. You can specify a number or a column range.

Default 1 if the length of the variable is undefined; otherwise, the length of the variable

Range 1–32767

Comparisons

The $*w*., $F*w*., and the $CHAR*w*. formats are identical, and they do not trim leading blanks. To trim leading blanks, use the LEFT function to left align character data before output.

Example

The following program illustrates the $*w*. format:

```
data _null_;
   declare char(15) a;
   method run();
      a=put(' Cary',$5.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= Cary
```

See Also

Functions:

- “LEFT Function” on page 816

B8601DAw. Format

Writes date values by using the ISO 8601 basic notation *yyyymmdd*.

Categories: Date and Time
ISO 8601

Alignment: Left

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.2.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601DA*w*.

Required Argument

w
specifies the width of the output field.

Default 10

Range 8–10

Details

The B8601DA format writes the date value by using the ISO 8601 basic date notation *yyyymmdd*:

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 0 and 31.

Example

The following example uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(20999,b8601da.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=20170629
```

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

B8601DNw. Format

Writes dates from datetime values by using the ISO 8601 basic notation *yyyymmdd*.

Categories: Date and Time
ISO 8601

Alignment: Left

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.2.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601DN*w*.

Required Argument

w
specifies the width of the output field.

Default 10

Range 8–10

Details

The B8601DN format writes the date from a datetime value by using the ISO 8601 basic date notation *yyyymmdd*:

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

Example

The following example uses the input value of 1793308532. 1793308532 is the SAS date value that corresponds to October 28, 2016.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(1793308532,b8601dn.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=  20161028
```

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

B8601DTw.d Format

Writes datetime values by using the ISO 8601 basic notation *yyyymmdd*T*hhmmss*<*ffffff*>.

Categories: Date and Time
ISO 8601

Alignment: Left

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.4.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601DT*w.d*

Required Arguments

w
specifies the width of the output field.

Default 19

Range 15–26

d
specifies the number of digits to the right of the seconds value that represents a fraction of a second. This argument is optional.

Default 0

Range 0–6

Details

The B8601DT format writes the datetime value by using the ISO 8601 basic datetime notation *yyyymmdd*T*hhmmss*<*ffffff*>:

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

ffffff
are optional fractional seconds, with a precision of up to six digits, where each digit is between 0 and 9.

Example

The following example uses the input value of 1793308532. 1793308532 is the SAS datetime value that corresponds to 9:15:32 p.m. on October 28, 2016.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(1793308532, b8601dt.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 20161028T211532
```

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

B8601DZw. Format

Writes datetime values for the zero meridian Coordinated Universal Time (UTC) time by using the ISO 8601 datetime and time zone basic notation *yyyymmdd*T*hhmmss*+0000.

Categories: Date and Time
ISO 8601

Alignment: Left

Supports: ISO 8601 Element 5.4.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601DZ*w*.

Required Argument

w
specifies the width of the output field.

Default 26

Range 20–35

Details

UTC values specify a time and a time zone based on the zero meridian in Greenwich, England. The B8601DZ format writes SAS datetime values for the zero meridian date and time by using one of the following ISO 8601 basic datetime notations:

- *yyyymmdd*T*hhmmss*+0000

  Note: Use this form when *w* is large enough to support this time zone notation.

- *yyyymmdd*T*hhmmss*Z

  Note: Use this form when *w* is not large enough to support the +0000 time zone notation.

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

+0000
indicates the UTC time for the zero meridian (Greenwich, England).

An ISO 8601 time or datetime value that specifies a time zone offset is adjusted by the number of hours and minutes that is specified in the offset. Then, the time zone offset is processed as the time or datetime for the zero meridian (Greenwich, England). The B8601DZ format always writes the datetime value by using the zero meridian offset value of +0000. To write a datetime that uses a time zone offset other than +0000, see “B8601LZw. Format” on page 94.

Restriction: The shorter form +00 is not supported.

Z
: indicates that the time is for the zero meridian (Greenwich, England) or +0000 UTC time. Z is used when the width of the format does not support the +0000 notation.

Example

The following example uses the input value of 1793308532. 1793308532 is the SAS date value that corresponds to 9:15:32 p.m. on October 28, 2016.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(1793308532,b8601dz.);
     put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=      20161028T211532+0000
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

B8601LZw. Format

Writes time values as local time by appending a time zone offset difference between the local time and UTC, using the ISO 8601 basic time notation *hhmmss*+|−*hhmm*.

Categories: Date and Time
ISO 8601

Alignment: Left

Supports: ISO 8601 Elements 5.3.3 and 5.3.4.2

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601LZ*w*.

Required Argument

w
specifies the width of the output field.

Default 14

Range 9–20

Details

The B8601LZ format writes time values without making any adjustments, and appends the UTC time zone offset for the local SAS session by using the ISO 8601 basic notation *hhmmss*+|–*hhmm*:

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

+|–*hhmm*
is an hour and minute signed offset from zero meridian time. Note that the offset must be +|–*hhmm* (that is, + or – and four characters).

Use + for time zones east of the zero meridian, and use – for time zones west of the zero meridian. For example, +0200 indicates a two-hour time difference to the east of the zero meridian, and –0600 indicates a six-hour time difference to the west of the zero meridian.

Restriction: The shorter form +|–*hh* is not supported.

When SAS reads a UTC time by using the B8601TZ informat, and the adjusted time is greater than 24 hours or less than 00 hours, SAS adjusts the value so that the time is between 000000 and 235959. If the B8601LZ format attempts to format a time outside this time range, the time is formatted with asterisks to indicate that the value is out of range.

Example

The following example uses the input value of 20999, which is a local time value of 054959-0000.

```
data _null_;
```

```
      declare varchar(30) a;
      method run();
         a=put(20999,b8601lz.);
         put a=;
      end;
   enddata;
   run;
```

SAS writes the following output to the log.

```
a=   054959-0000
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

B8601TMw.d Format

Writes time values by using the ISO 8601 basic notation *hhmmss<ffff>*.

Categories: Date and Time
ISO 8601

Alignment: Left

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.3.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601TM*w.d*

Required Arguments

w
specifies the width of the output field.

Default 8

Range 6–15

d
specifies the number of digits to the right of the seconds value that represents a fraction of a second. This argument is optional.

Default 0

Range 0–6

Details

The B8601TM format writes SAS time values by using the ISO 8601 basic time notation *hhmmss<ffffff>*:

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

ffffff
are optional fractional seconds, with a precision of up to six digits, where each digit is between 0 and 9.

Example

The following example uses the input value of 20999, which corresponds to a time value of 054959.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(20999,b8601tm.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=054959
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

B8601TZw. Format

Adjusts time values to the Coordinated Universal Time (UTC) and writes the time values by using the ISO 8601 basic time notation *hhmmss+|–hhmm*.

Categories: Date and Time
ISO 8601

Alignment: Left

Supports: ISO 8601 Elements 5.3.3 and 5.3.4

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

B8601TZ*w*.

Required Argument

w
specifies the width of the output field.

Default 14

Range 9–20

Details

UTC time values specify a time and a time zone based on the zero meridian in Greenwich, England. The B8601TZ format adjusts the time value to be the time at the zero meridian and writes the time value in one of the following ISO 8601 basic time notations:

- *hhmmss+|–hhmm*

  Note: Use this form when *w* is large enough to support this time notation.

- *hhmmss*Z

Note: Use this form when *w* is not large enough to support the +|–*hhmm* time zone notation.

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

+|–*hh:mm*
is an hour and minute signed offset from zero meridian time. Note that the offset must be +|–*hhmm* (that is, + or – and four characters).

Use + for time zones east of the zero meridian, and use – for time zones west of the zero meridian. For example, +0200 indicates a two-hour time difference to the east of the zero meridian, and –0600 indicates a six-hour time difference to the west of the zero meridian.

Restriction: The shorter form +|–*hh* is not supported.

Z
indicates that the time is for zero meridian (Greenwich, England) or +0000 UTC time. Z is used when the width of the format does not support the +0000 notation.

When SAS reads a UTC time by using the B8601TZ informat, and the adjusted time is greater than 24 hours or less than 00 hours, SAS adjusts the value so that the time is between 000000 and 240000. If the B8601TZ format attempts to format a time outside this time range, the time is formatted with asterisks to indicate that the value is out of range.

Comparisons

- For time values between 000000 and 240000, the B8601TZ format adjusts the time value to be the time at the zero meridian and writes the time value in the international standard extended time notation.
- The B8601LZ format makes no adjustment to the time and writes time values in the international standard extended time notation, using a UTC time zone offset for the local SAS session.

Example

The following example uses the input value of 20999, which corresponds to a time value of 054959+0000.

```
data _null_;
   declare varchar(30) a;
   method run();
```

```
        a=put(20999,b8601tz.);
        put a=;
    end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=   054959+0000
```

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

BESTw. Format

SAS chooses the best notation.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

BEST*w*.

Required Argument

w

specifies the width of the output field.

Default 12

Range 1–32

Tip If you print numbers between 0 and .01 exclusively, then use a field width of at least 7 to avoid excessive rounding. If you print numbers between 0 and –.01 exclusively, use a field width of at least 8.

Details

The BEST*w*. format is the default format for writing numeric values. When there is no format specification, SAS chooses the format that provides the most information about the value according to the available field width. BEST*w*. rounds the value, and if SAS can display at least one significant digit in the decimal portion, within the width specified, BEST*w*. produces the result in decimal. Otherwise, it produces the result in scientific notation. SAS always stores the complete value regardless of the format that you use to represent it.

Comparisons

- The BEST*w*. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.
- The BESTDOTX*w*. format writes as many significant digits as possible in the output field. Integers are printed with a decimal.
- The D*w.p* format writes numbers with the desired precision and more alignment than the BEST*w*. format.
- The *w.d* format aligns decimal points, if possible, but does not necessarily show the same precision for all numbers.

Example

The following program illustrates the BEST*w*. format:”

```
data _null_;
   declare varchar(30) a b;
   method run();
      a=put(1257000,best6.);
      b=put(1257000,best3.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=1.26E6 b=1E6
```

See Also

Formats:

- “BESTDw.p Format” on page 103
- “BESTDOTXw. Format” on page 102
- “Dw.p Format” on page 110
- “w.d Format” on page 201

BESTDOTXw. Format

Specifies that SAS choose the best notation and use a dot as a decimal separator.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS System Options: Reference*.

Syntax

BESTDOTX.*w*.

Required Argument

w

specifies the width of the output field.

Default 12

Range 1–32

Tip If you print numbers between 0 and .01 exclusively, then use a field width of at least 7 to avoid excessive rounding. If you print numbers between 0 and –.01 exclusively, use a field width of at least 8.

Details

If the NLDECSEPARATOR system option is disabled, the BEST*w*. and BESTDOTX*w*. formats process data the same way. If the NLDECSEPARATOR system option is

enabled, then the results from the BEST*w*. and BESTDOTX*w*. formats are different. See the following table to understand the differences:

LOCALE option	Default decimal separator character for the locale	NLDECSEPARATOR option	Separator character used by BEST*w*.	Separator character used by BESTDOTX*w*.
en_US	Dot	Disabled (default)	Dot	Dot
		Enabled	Dot	Dot
fr_FR	Comma	Disabled (default)	Dot	Dot
		Enabled	Comma	Dot

For more information about the NLDECSEPARATOR system option, see *SAS National Language Support (NLS): Reference Guide*.

Comparisons

- The BESTDOTX*w* format writes as many significant digits as possible in the output field. Integers are printed with a decimal.
- The BEST*w*. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.

See Also

Formats:

- "BESTw. Format" on page 100

BESTDw.p Format

Prints numeric values, lining up decimal places for values of similar magnitude, and prints integers without decimals.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more

information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

BESTD*w*.[*p*]

Required Argument

w

specifies the width of the output field.

Default 12

Range 1–32

Optional Argument

p

specifies the precision.

Default 3

Range 0 to *w*–1

Requirement must be less than *w*

Tip If *p* is omitted or is specified as 0, then *p* is set to 3.

Details

The BESTD*w.p* format writes numbers so that the decimal point aligns in groups of values with similar magnitude. Integers are printed without a decimal point. Larger values of *p* print the data values with more precision and potentially more shifts in the decimal point alignment. Smaller values of *p* print the data values with less precision and a greater chance of decimal point alignment.

The format chooses the number of decimal places to be printed for ranges of values, even when the underlying values can be represented with fewer decimal places.

Comparisons

- The BEST*w*. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up. Integers are printed without a decimal.
- The BESTD*w.p* format is a combination of the BEST*w*. format and the D*w.p* format in that it formats all numeric data, and it does a better job of aligning decimals than the BEST*w*. format.
- The D*w.p* format writes numbers with the desired precision and more alignment than the BEST*w* format.
- The *w.d* format aligns decimal points, if possible, but it does not necessarily show the same precision for all numbers.

Example

The following program illustrates the BESTD*w.p* format:

```
data _null_;
   declare varchar(30) a b c d e;
   method run();
      a=put(12345, bestd14.);
      b=put(123.45, bestd14.);
      c=put(1.2345, bestd14.);
      d=put(.12345, bestd14.);
      e=put(1.23456789, bestd14.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=         12345 b=   123.4500000 c=     1.2345000 d=     0.1234500 e=     1.2345679
```

BINARYw. Format

Converts numeric values to binary representation.

Category: Numeric

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

BINARY*w*.

Required Argument

w
specifies the width of the output field.

Default 8

Range 1–64

Comparisons

BINARY*w*. converts numeric values to binary representation. The $BINARY*w*. format converts character values to binary representation.

Example

The following program illustrates the BINARY*w*. format:

```
data _null_;
   declare varchar(30) a b c;
   method run();
      a = put (123.45, binary8.);
      b = put (123, binary8.);
      c = put (-123, binary8.);
      put a= b= c=;
   end;
```

```
enddata;
run;
```

SAS writes the following output to the log.

```
a=01111011 b=01111011 c=10000101
```

See Also

Formats:

- "$BINARYw. Format" on page 75

COMMAw.d Format

Writes numeric values with a comma that separates every three digits and a period that separates the decimal fraction.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

COMMA*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 1–32

Tip Make *w* wide enough to write the numeric values, the commas, and the optional decimal point.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than *w*

Comparisons

- The COMMA*w.d* format is similar to the COMMAX*w.d* format, but the COMMAX*w.d* format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The COMMA*w.d* format is similar to the DOLLAR*w.d* format except that the COMMA*w.d* format does not print a leading dollar sign.

Example

The following program illustrates the COMMA*w.* format:

```
data _null_;
   declare varchar(30) a b;
   method run();
      a=put (23451.23,comma10.2);
      b=put (123451.234,comma10.2);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 23,451.23 b=123,451.23
```

See Also

Formats:

- “COMMAXw.d Format” on page 109
- “DOLLARw.d Format” on page 123

COMMAXw.d Format

Writes numeric values with a period that separates every three digits and a comma that separates the decimal fraction.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

COMMAX[*w*.*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 1–32

Tip Make *w* wide enough to write the numeric values, the commas, and the optional decimal point.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than *w*

Comparisons

The COMMA*w.d* format is similar to the COMMAX*w.d* format, but the COMMAX*w.d* format reverses the roles of the decimal point and the comma. This convention is common in European countries.

Example

The following program illustrates the COMMAX*w*. format:

```
data _null_;
   declare varchar(15) a b;
   method run();
      a=put (23451.23,commax10.2);
      b=put (123451.234,commax10.2);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 23.451,23 b=123.451,23
```

See Also

Formats:

- “COMMAw.d Format” on page 107

Dw.p Format

Prints numeric values, possibly with a great range of values, lining up decimal places for values of similar magnitude.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding

or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

D[*w.p*]

Required Arguments

w

specifies the width of the output field.

Default 12

Range 1–32

p

specifies the significant digits.

Default 3

Range 0–16

Requirement must be less than *w*

Details

The D*w.p* format writes numbers so that the decimal point aligns in groups of values with similar magnitude. Larger values of *p* print the data values with more precision and potentially more shifts in the decimal point alignment. Smaller values of *p* print the data values with less precision and a greater chance of decimal point alignment.

Comparisons

- The BEST*w*. format writes as many significant digits as possible in the output field, but if the numbers vary in magnitude, the decimal points do not line up.
- D*w.p* writes numbers with the desired precision and more alignment than BEST*w*. format

Example

The following program illustrates the D*w.p* format:

```
data _null_;
   declare char(15) a b c d e f;
   method run();
      a=put (12345,d10.4);
      b=put (1234.5,d10.4);
      c=put (123.45,d10.4);
      d=put (12.345,d10.4);
      e=put (1.2345,d10.4);
      f=put (.12345,d10.4);
      put a= b= c= d= e= f=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=   12345.0      b=    1234.5      c= 123.45000
d=  12.34500      e=   1.23450      f=0.12345
```

Formats:

- "BESTw. Format" on page 100

DATEw. Format

Writes SAS date values in the form *ddmmmyy*, *ddmmmyyyy*, or *dd-mmm-yyyy*.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DATE*w*.

Required Argument

w
specifies the width of the output field.

Default 7

Range 5–11

Tip Use a width of 9 to print a 4-digit year without a separator between the day, month, and year. Use a width of 11 to print a 4-digit year using a hyphen as a separator between the day, month, and year.

Details

The DATE*w*. format writes SAS date values in the form *ddmmmyy*, *ddmmmyyyy*, or *dd-mmm-yyyy*. Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

mmm
is the first three letters of the month name.

yy or *yyyy*
is a two-digit or four-digit integer that represents the year.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(15) a b c d e;
   method run();
      a=put (20999,date5.);
      b=put (20999,date6.);
      c=put (20999,date7.);
      d=put (20999,date8.);
      e=put (20999,date9.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=29JUN b= 29JUN c=29JUN17 d= 29JUN17 e=29JUN2017
```

Functions:

- "DATE Function" on page 500

DATEAMPMw.d Format

Writes SAS datetime values in the form *ddmmmyy:hh:mm:ss.ss* with AM or PM.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DATEAMPM*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 19

Range 7–40

Tip SAS requires a minimum *w* value of 13 to write AM or PM. For widths between 10 and 12, SAS writes a 24-hour clock time.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the seconds value.

Range 0–39

Requirement must be less than *w*

Note If *w*–*d*< 17, SAS truncates the decimal values.

Details

The DATEAMPM*w.d* format writes SAS datetime values in the form *ddmmmyy:hh:mm:ss.ss*. Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

mmm
is the first three letters of the month name.

yy
is a two-digit integer that represents the year.

hh
is an integer that represents the hour.

mm
is an integer that represents the minutes.

ss.ss
is the number of seconds to two decimal places.

Comparisons

The DATEAMPM*w.d* format is similar to the DATETIME*w.d* format except that DATEAMPM*w.d* prints AM or PM at the end of the time.

Example

The example table uses the input value of 1823167525.18123167525 is the SAS datetime value that corresponds to 11:25:25 AM on October 9, 2017.

```
data _null_;
   declare varchar(15) a b c d e;
   method run();
      a=put (1823167525,dateampm.);
      b=put (1823167525,dateampm7.);
      c=put (1823167525,dateampm10.);
      d=put (1823167525,dateampm13.);
      e=put (1823167525,dateampm22.2);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=09OCT17:11:25:2 b=09OCT17 c=09OCT17:11 d=09OCT17:11 AM e=09OCT17:11:25:2
```

Formats:

- "DATETIMEw.d Format" on page 116

DATETIMEw.d Format

Writes SAS datetime values in the form *ddmmmyy:hh:mm:ss.ss*.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DATETIME*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 16

Range 7–40

Tip SAS requires a minimum *w* value of 16 to write a SAS datetime value with the date, hour, and seconds. Add two places to *w* and a value to *d* to return values with optional decimal fractions of seconds.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the seconds value.

Range 0–39

Requirement must be less than *w*

Details

The DATETIME*w.d* format writes SAS datetime values in the form *ddmmmyy:hh:mm:ss.ss*. Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

mmm
is the first three letters of the month name.

yy
is a two-digit integer that represents the year.

hh
is an integer that represents the hour in 24-hour clock time.

mm
is an integer that represents the minutes.

ss.ss
is the number of seconds to two decimal places.

Note: If *w*–*d*<17, SAS truncates the decimal values.

Comparisons

The DATEAMPM*w.d* format is similar to the DATETIME*w.d* format except that DATEAMPM*w.d* prints AM or PM at the end of the time.

Example

The example table uses the input value of 1817623985.1817623985 is the SAS datetime value that corresponds to 7:33:05 AM on August 6, 2017.

```
data _null_;
   declare varchar(15) a b c d e f g h;
   method run();
      a=put (1817623985,datetime.);
```

```
        b=put (1817623985,datetime7.);
        c=put (1817623985,datetime12.);
        d=put (1817623985,datetime18.);
        e=put (1817623985,datetime18.1);
        f=put (1817623985,datetime19.);
        g=put (1817623985,datetime20.1);
        h=put (1817623985,datetime21.2);
        put a= b= c= d= e= f= g= h=;
    end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=06AUG17:07:33:0 b=06AUG17 c=  06AUG17:07 d=  06AUG17:07:33 e=06AUG17:07:33:0
f=06AUG2017:07:3 g=06AUG2017:07:33 h=06AUG2017:07:33
```

DAYw. Format

Writes SAS date values as the day of the month.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DAY*w*.

Required Argument

w
specifies the width of the output field.

Default 2

Range 2–32

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 28, 2017.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(20999,day2.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=29
```

"DS2 Expressions" in *SAS DS2 Programmer's Guide*

DDMMYYw. Format

Writes SAS date values in the form *ddmm<yy>yy* or *dd/mm/<yy>yy*, where a forward slash is the separator and the year appears as either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding

or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DDMMYY*w*.

Required Argument

w
specifies the width of the output field.

Default 8

Range 2–10

Interaction When *w* has a value of from 2 to 5, the date appears with as much of the day and the month as possible. When *w* is 7, the date appears as a two-digit year without slashes.

Details

The DDMMYY*w*. format writes SAS date values in the form *ddmm<yy>yy* or *dd/mm/<yy>yy*. Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

/
is the separator.

mm
is an integer that represents the month.

<yy>yy
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(15) a b c d e f;
   method run();
      a=put(20999,ddmmyy.);
      b=put(20999,ddmmyy5.);
      c=put(20999,ddmmyy6.);
      d=put(20999,ddmmyy7.);
```

```
        e=put(20999,ddmmyy8.);
        f=put(20999,ddmmyy10.);
        put a= b= c= d= e= f=;
    end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=29/06/17 b=29/06 c=290617 d= 290617 e=29/06/17 f=29/06/2017
```

Functions:

- "MDY Function" on page 857

DDMMYYxw. Format

Writes SAS date values in the form *ddmm<yy>yy* or *dd-mm-yy<yy>*, where *x* in the format name is a character that represents the special character that separates the day, month, and year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

DDMMYY*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the day, the month, and the year. Here are the valid values:

B
separates with a blank

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a slash.

w

specifies the width of the output field.

Default 8

Range 2–10

Interactions When *w* has a value of from 2 to 5, the date appears with as much of the day and the month as possible. When *w* is 7, the date appears as a two-digit year without separators.

When *x* has a value of N, the width range changes to 2–8.

Details

The DDMMYY*xw*. format writes SAS date values in the form *ddmm*<*yy*>*yy* or *dd*X*mm*X<*yy*>*yy*. Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

X
is a specified separator.

mm
is an integer that represents the month.

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(15) a b c d;
   method run();
      a=put(20999,ddmmyyc5.);
      b=put(20999,ddmmyyd8.);
      c=put(20999,ddmmyyn8.);
      d=put(20999,ddmmyyp10.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=29:06 b=29-06-17 c=29062017 d=29.06.2017
```

DOLLARw.d Format

Writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DOLLAR*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 2–32

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than *w*

Details

The DOLLAR*w.d* format writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

Comparisons

- The DOLLAR*w.d* format is similar to the DOLLARX*w.d* format, but the DOLLARX*w.d* format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The DOLLAR*w.d* format is the same as the COMMA*w.d* format except that the COMMA*w.d* format does not write a leading dollar sign.

Example

The following program illustrates the DOLLAR*w.d* format:

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(1254.71,dollar10.2);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= $1,254.71
```

See Also

Formats:

- "COMMAw.d Format" on page 107
- "DOLLARXw.d Format" on page 125

DOLLARXw.d Format

Writes numeric values with a leading dollar sign, a period that separates every three digits, and a comma that separates the decimal fraction.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DOLLARX*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 2–32

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0–31

Requirement must be less than *w*

Details

The DOLLARX*w.d* format writes numeric values with a leading dollar sign, a comma that separates every three digits, and a period that separates the decimal fraction.

Comparisons

- The DOLLARX*w.d* format is similar to the DOLLAR*w.d* format, but the DOLLARX*w.d* format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The DOLLARX*w.d* format is the same as the COMMAX*w.d* format except that the COMMA*w.d* format does not write a leading dollar sign.

Example

The following program illustrates the DOLLARX*w.d* format:

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(1254.71,dollarx10.2);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= $1.254,71
```

See Also

Formats:

- “COMMAXw.d Format” on page 109
- “DOLLARw.d Format” on page 123

DOWNAMEw. Format

Writes SAS date values as the name of the day of the week.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DOWNAME*w*.

Required Argument

w
specifies the width of the output field.

Default 9

Range 1–32

Tip If you omit *w*, SAS prints the entire name of the day.

Details

If necessary, SAS truncates the name of the day to fit the format width. For example, the format DOWNAME2. prints the first two letters of the day name.

Example

The following program illustrates the DOWNAME*w*. format:

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(20999,downame.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= Thursday
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "WEEKDAYw. Format" on page 207

DTDATEw. Format

Expects a SAS datetime value as input and writes the SAS date values in the form *ddmmmyy* or *ddmmmyyyy*.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DTDATE*w*.

Required Argument

w
specifies the width of the output field.

Default 7

Range 5–9

Tip Use a width of 9 to print a 4-digit year.

Details

The DTDATE*w*. format writes SAS date values in the form *ddmmmyy* or *ddmmmyyyy*. Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

mmm
are the first three letters of the month name.

yy or *yyyy*
is a two-digit or four-digit integer that represents the year.

Comparisons

The DTDATE*w*. format produces the same type of output that the DATE*w*. format produces. The difference is that the DTDATE*w*. format requires a SAS datetime value.

Example

The example table uses the input value of 1823167525 and prints both a two-digit and a four-digit year for the DTDATE*w*. format. 1823167525 is the SAS datetime value that corresponds to 11:25:25 AM on October 9, 2017.

```
data _null_;
   declare varchar(15) a b;
   method run();
      a=put(1823167525,dtdate.);
      b=put(1823167525,dtdate9.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=09OCT17 b=09OCT2017
```

Formats:

- "DATEw. Format" on page 112

DTMONYYw. Format

Writes the date part of a SAS datetime value as the month and year in the form *mmmyy* or *mmmyyyy*.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DTMONYY*w*.

Required Argument

w
specifies the width of the output field.

Default 5

Range 5–7

Details

The DTMONYY*w*. format writes SAS datetime values in the form *mmmyy* or *mmmyyyy*. Here is an explanation of the syntax:

mmm
is the first three letters of the month name.

yy or *yyyy*
is a two–digit or four-digit integer that represents the year.

Comparisons

The DTMONYY*w*. format and the MONYY*w*. format are similar in that they both write date values. The difference is that DTMONYY*w*. expects a SAS datetime value as input, and MONYY*w*. expects a SAS date value.

Example

The example table uses as input the value 1823167525. 1823167525 is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 AM.

```
data _null_;
   declare varchar(15) a b c d;
   method run();
      a=put(1823167525,dtmonyy.);
      b=put(1823167525,dtmonyy5.);
      c=put(1823167525,dtmonyy6.);
      d=put(1823167525,dtmonyy7.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=OCT17 b=OCT17 c= OCT17 d=OCT2017
```

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "DATETIMEw.d Format" on page 116
- "MONYYw. Format" on page 180

DTWKDATXw. Format

Writes the date part of a SAS datetime value as the day of the week and the date in the form *day-of-week*, *dd month-name yy* (or *yyyy*).

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DTWKDATX*w*.

Required Argument

w

specifies the width of the output field.

Default 29

Range 3–37

Details

The DTWKDATX*w*. format writes SAS date values in the form *day-of-week*, *dd*, *month-name*, *yy*, or *yyyy*. Here is an explanation of the syntax:

day-of-week
is either the first three letters of the day name or the entire day name.

dd
is an integer that represents the day of the month.

month-name
is either the first three letters of the month name or the entire month name.

yy or *yyyy*
is a two-digit or four-digit integer that represents the year.

Comparisons

The DTWKDATX*w*. format is similar to the WEEKDATX*w*. format in that they both write date values. The difference is that DTWKDATX*w*. expects a SAS datetime value as input, and WEEKDATX*w*. expects a SAS date value.

Example

The example table uses as input the value 1823167525. 1823167525 is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 a.m.

```
data _null_;
   declare varchar(30) a b c d;
   method run();
      a=put(1823167525,dtwkdatx.);
      b=put(1823167525,dtwkdatx3.);
      c=put(1823167525,dtwkdatx8.);
      d=put(1823167525,dtwkdatx25.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=       Monday, 9 October 2017 b=Mon c=     Mon d=       Monday, 9 Oct 2017
```

- “WEEKDATXw. Format” on page 205

DTYEARw. Format

Writes the date part of a SAS datetime value as the year in the form *yy* or *yyyy*.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

DTYEAR*w*.

Required Argument

w
specifies the width of the output field.

Default 4

Range 2–4

Comparisons

The DTYEAR*w*. format is similar to the YEAR*w*. format in that they both write date values. The difference is that DTYEAR*w*. expects a SAS datetime value as input, and YEAR*w*. expects a SAS date value.

Example

The example table uses as input the value 1823167525.1823167525 is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 a.m.

```
data _null_;
   declare varchar(15) a b c d;
```

```
      method run();
         a=put(1823167525,dtyear.);
         b=put(1823167525,dtyear2.);
         c=put(1823167525,dtyear3.);
         d=put(1823167525,dtyear4.);
         put a= b= c= d=;
      end;
   enddata;
   run;
```

SAS writes the following output to the log.

```
a=2017 b=17 c= 17 d=2017
```

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "DATETIMEw.d Format" on page 116
- "YEARw. Format" on page 208

DTYYQCw. Format

Writes the date part of a SAS datetime value as the year and the quarter and separates them with a colon (:).

Category: Date and Time

Alignment: Right

Note:

Syntax

DTYYQC*w*.

Required Argument

w
specifies the width of the output field.

Default 4

Range 4–6

Details

The DTYYQC*w*. format writes SAS datetime values in the form *yy* or *yyyy*, followed by a colon (:) and the numeric value for the quarter of the year.

Example

The example table uses as input the value 1823167525. 1823167525 is the SAS datetime value that corresponds to October 9, 2017, at 11:25:25 p.m.

```
data _null_;
   declare varchar(15) a b c d;
   method run();
      a=put(1823167525,dtyyqc.);
      b=put(1823167525,dtyyqc4.);
      c=put(1823167525,dtyyqc5.);
      d=put(1823167525,dtyyqc6.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17:4 b=17:4 c= 17:4 d=2017:4
```

E8601DAw. Format

Writes date values by using the ISO 8601 extended notation *yyyy-mm-dd*.

Categories: Date and Time
ISO 8601

Alignment: Left

Alias: IS8601DA*w*.

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.2.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601DA*w*.

Required Argument

w
specifies the width of the output field.

Default 10

Requirement The width of the output field must be 10.

Details

The E8601DA format writes a date by using the ISO 8601 extended notation *yyyy-mm-dd*:

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

Example

The following example uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(20999,e8601da.);
```

```
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=2017-06-29
```

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

E8601DNw. Format

Writes dates from SAS datetime values by using the ISO 8601 extended notation *yyyy-mm-dd*.

Categories: Date and Time
ISO 8601

Alignment: Left

Alias: IS8601DN

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.2.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601DN*w*.

Required Argument

w
specifies the width of the input field.

Default 10

Requirement The width of the input field must be 10.

Details

The E8601DN format writes the date by using the ISO 8601 extended date notation *yyyy-mm-dd*:

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

Example

The following example uses the input value of 1793308532. 1793308532 is the SAS date value that corresponds to October 28, 2016.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(1793308532,e8601dn.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=2016-10-28
```

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

E8601DTw.d Format

Writes datetime values by using the ISO 8601 extended notation *yyyy-mm-dd*T*hh:mm:ss.ffffff*.

Categories: Date and Time
ISO 8601

Alignment: Left

Alias: IS8601DT*w.d*

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.4.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601DT*w.d*

Required Arguments

w
specifies the width of the input field.

Default 19

Range 16–26

d
specifies the number of digits to the right of the decimal point in the seconds value. This argument is optional.

Default 0

Range 0–6

Details

The E8601DT format writes datetime values by using the ISO 8601 extended datetime notation *yyyy-mm-dd*T*hh:mm:ss.ffffff*:

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

ffffff
are optional fractional seconds, with a precision of up to six digits, where each digit is between 0 and 9.

Note: If you specify a width of 16, SAS assumes that the value for seconds is 0 and omits them from the output.

Example

The following example uses the input value of 1793308532. 1793308532 is the SAS datetime value that corresponds to 9:15:32pm on October 28, 2016.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(1793308532,e8601dt.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=2016-10-28T21:1
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

E8601DZw. Format

Writes datetime values for the zero meridian Coordinated Universal Time (UTC) time by using the ISO 8601 datetime and time zone extended notation *yyyy-mm-dd*T*hh:mm:ss*+00:00.

Categories:	Date and Time ISO 8601
Alignment:	Left
Alias:	IS8601DZ*w*.
Supports:	ISO 8601 Element 5.4.1, complete representation
Note:	Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding

or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601DZ*w*.

Required Argument

w
specifies the width of the output field.

Default 26

Range 20–35

Details

UTC values specify a time and a time zone based on the zero meridian in Greenwich, England. The E8601DZ format writes SAS datetime values by using one of the following ISO 8601 extended datetime notations:

- *yyyy-mm-dd*T*hh:mm:ss*+00:00

  Note: Use this form when *w* is large enough to support this time zone notation.

- *yyyy-mm-dd*T*hh:mm:ss*Z

  Note: Use this form when *w* is not large enough to support the +00:00 time zone notation.

yyyy
is a four-digit year.

mm
is a two-digit month (zero padded) between 01 and 12.

dd
is a two-digit day of the month (zero padded) between 01 and 31.

hh
is a two-digit hour (zero padded) between 00 and 24.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

+00:00
indicates that the time is for zero meridian (Greenwich, England) time.

An ISO 8601 time or datetime value that specifies a time zone offset is adjusted by the number of hours and minutes that is specified in the offset and processed as the time or datetime for the zero meridian (Greenwich, England). The E8601DZ format always writes the datetime value by using the zero meridian offset value of +00:00. To write a datetime that uses the UTC offset other than +00:00, see "E8601LZw. Format" in *SAS Formats and Informats: Reference*.

Restriction: The shorter form +00 is not supported.

Z
indicates that the time is for zero meridian (Greenwich, England) or +00:00 UTC time. Z is used when the width of the format does not support the +00:00 notation.

Example

The following example uses the input value of 1793308532. 1793308532 is the SAS date value that corresponds to 2016-10-28T21:15:32+00:00.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(1793308532,e8601dz.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 2016-10-28T21:15:32+00:00
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

E8601LZw. Format

Writes time values as local time, appending the Coordinated Universal Time (UTC) offset for the local SAS session, using the ISO 8601 extended time notation *hh:mm:ss+|–hh:mm*.

Categories: Date and Time
ISO 8601

Alignment: Left

Alias: IS8601LZ*w*.

Supports: ISO 8601 Element 5.3.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601LZ*w*.

Required Argument

w
specifies the width of the output field.

Default 14

Range 9–20

Details

The E8601LZ format writes time values without making any adjustments, and appends the UTC time zone offset for the local SAS session by using one of the following ISO 8601 extended time notations:

- *hh:mm:ss*+|–*hh:mm*

  Note: Use this form when *w* is large enough to support this time notation.

- *hh:mm:ss*Z

  Note: Use this form when *w* is not large enough to support the +|– *hh:mm* time zone notation.

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

+|–*hh:mm*
is an hour and minute signed offset from zero meridian time. Note that the offset must be +|–*hh:mm* (that is, + or – and five characters).

Use + for time zones east of the zero meridian, and use – for time zones west of the zero meridian. For example, +02:00 indicates a two-hour time difference to the east of the zero meridian, and –06:00 indicates a six-hour time difference to the west of the zero meridian.

Restriction: The shorter form +|–*hh* is not supported.

Z
indicates zero meridian (Greenwich, England) or +00:00 UTC time.

SAS writes the time value by using the form *hh:mm.ffffff*, and appends the time zone indicator +|–*hh:mm* based on the time zone offset from the zero meridian for the local SAS session, or Z. The Z time zone indicator is used for format lengths that are less than 14.

If the same time is written using both zone indicators, they indicate two different times based on the UTC. For example, if the local SAS session uses Eastern Time in the U.S., and the time value is 45824, SAS would write 12:43:44–04:00 or 12:43:44Z. The time 12:43:44–04:00 is the time 16:43:44+00:00 at the zero meridian. The Z indicates that the time is the time at the zero meridian, or 12:43:44+00:00.

When SAS reads a UTC time by using the E8601TZ informat, and the adjusted time is greater than 24 hours or less than 00 hours, SAS adjusts the value so that the time is between 00:00:00 and 24:00:00. If the E8601LZ format attempts to format a time outside of this time range, the time is formatted with asterisks to indicate that the value is out of range.

Example

The following example uses the input value of 20999, which is a local time value of 05:49:59-04:00.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(20999,e8601lz.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=05:49:59-04:00
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

E8601TMw.d Format

Writes time values by using the ISO 8601 extended notation *hh:mm:ss.ffffff*.

Categories: Date and Time
ISO 8601

Alignment: Left

Alias: IS8601TM*w.d*

Restriction: UTC time zone offset values are not supported.

Supports: ISO 8601 Element 5.3.1.1, complete representation, and 5.3.1.3, representation of decimal fractions

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601TM*w.d*

Required Arguments

w

specifies the width of the output field.

Default 8

Range 8–15

d

specifies the number of digits to the right of the decimal point in the seconds value. This argument is optional.

Default 0

Range 0–6

Details

The E8601TM format writes SAS time values by using the ISO 8601 extended time notation *hh:mm:ss.ffffff*:

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

.ffffff
are optional fractional seconds, with a precision of up to six digits, where each digit is between 0 and 9.

Example

The following example uses the input value of 20999, which corresponds to a time value of 05:49:59.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(20999,e8601tm.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=05:49:59
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

E8601TZw.d Format

Adjusts time values to the Coordinated Universal Time (UTC) and writes the time values by using the ISO 8601 extended notation *hh:mm:ss.<fff>+|–hh:mm*.

Categories: Date and Time
ISO 8601

Alignment: Left

Alias: IS8601TZ*w.d*

Supports: ISO 8601 Element 5.3.1.1, complete representation

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E8601TZ*w.d*

Required Arguments

w

specifies the width of the output field.

Default 14

Range 9–20

d

specifies the number of digits to the right of the decimal point in the seconds value. This argument is optional.

Default 0

Range 0–6

Details

UTC time values specify a time and a time zone based on the zero meridian in Greenwich, England. The E8601TZ format writes time values in one of the following ISO 8601 extended time notations:

- *hh:mm:ss<.fff>+|–hh:mm*

  Note: Use this form when *w* is large enough to support this time zone notation.

- *hh:mm:ss*Z

  Note: Use this form when *w* is not large enough to support the +|–*hh:mm* time zone notation.

hh
is a two-digit hour (zero padded) between 00 and 23.

mm
is a two-digit minute (zero padded) between 00 and 59.

ss
is a two-digit second (zero padded) between 00 and 59.

fff
are optional fractional seconds.

+|–*hh:mm*
is an hour and minute signed offset from zero meridian time. The offset must be +|–*hh:mm* (that is, + or – and five characters).

Restriction: The shorter form +|–*hh* is not supported.

Use + for time zones east of the zero meridian, and use – for time zones west of the zero meridian. For example, +02:00 indicates a two-hour time difference to the east of the zero meridian, and –06:00 indicates a six- hour time difference to the west of the zero meridian.

Z
indicates zero meridian (Greenwich, England) or +00:00 UTC time.

When SAS reads a UTC time by using the E8601TZ informat, and the adjusted time is greater than 24 hours or less than 00 hours, SAS adjusts the value so that the time is between 00:00:00 and 24:00:00. If the E8601TZ format attempts to format a time outside of this time range, the time is formatted with asterisks to indicate that the value is out of range.

Comparisons

For time values between 00:00:00 and 24:00:00, the time value E8601TZ format adjusts the time value to be the time at the zero meridian and writes the time value in the international standard extended time notation. The E8601LZ format makes no adjustment to the time and writes time values in the international standard extended time notation, using a UTC time zone offset for the local SAS session.

Example

The following example uses the input value of 20999, which corresponds to a time value of 05:49:59+00:00.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(20999,e8601tz.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=05:49:59+00:00
```

See Also

"Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*

Ew. Format

Writes numeric values in scientific notation.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

E*w*.

Required Argument

w
specifies the width of the output field.

Default 12

Range 7–32

Details

SAS reserves the first column of the result for a minus sign.

Example

The example uses the input value of 1257.

```
data _null_;
   declare char(15) a b;
   method run();
      a=put(1257,e10.);
      b=put(-1257,e10.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 1.257E+03      b=-1.257E+03
```

EUROw.d Format

Writes numeric values with a leading euro symbol (E), a comma that separates every three digits, and a period that separates the decimal fraction.

Category: Numeric

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

EURO*w.d*

Required Arguments

w

specifies the width of the output field.

Default 6

Range 1-32

Tip If you want the euro symbol to be part of the output, be sure to choose an adequate width.

d

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0-31

Requirement must be less than *w*

Comparisons

- The EURO*w.d* format is similar to the EUROX*w.d* format, but EUROX*w.d* format reverses the roles of the decimal point and the comma. This convention is common in European countries.
- The EURO*w.d* format is similar to the DOLLAR*w.d* format, except that DOLLAR*w.d* format writes a leading dollar sign instead of the euro symbol.

Note: The EUROX*w.d* format uses the euro character (U+20AC). If you use the DBCS version of SAS and an encoding that does not support the euro character, an error occurs. To prevent this error, change your session encoding to an encoding that supports the euro character.

Example

The following program illustrates the EURO*w.d* format:

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(1254.71,euro10.2);
      b=put(1254.71,euro5.);
      c=put(1254.71,euro9.2);
      d=put(1254.71,euro15.3);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= €1,254.71      b=€1255          c=€1,254.71       d=     €1,254.710
```

See Also

Formats:

■ “EUROXw.d Format” on page 153

EUROXw.d Format

Writes numeric values with a leading euro symbol (E), a period that separates every three digits, and a comma that separates the decimal fraction.

Category: Numeric

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

EUROX*w.d*

Required Arguments

w

specifies the width of the output field.

Default 6

Range 1 – 32

Tip If you want the euro symbol to be part of the output, be sure to choose an adequate width.

d

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0 – 31

Requirement must be less than *w*

Comparisons

- The EUROX*w.d* format is similar to the EURO*w.d* format, but EURO*w.d* format reverses the roles of the comma and the decimal point. This convention is common in English-speaking countries.
- The EUROX*w.d* format is similar to the DOLLARX*w.d* format, except that DOLLARX*w.d* format writes a leading dollar sign instead of the euro symbol.

Note: The EUROX*w.d* format uses the euro character (U+20AC). If you use the DBCS version of SAS and an encoding that does not support the euro character, an error occurs. To prevent this error, change your session encoding to an encoding that supports the euro character.

Example

The following program illustrates the EUROX*w.d* format:

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(1254.71,eurox10.2);
      b=put(1254.71,eurox5.);
      c=put(1254.71,eurox9.2);
      d=put(1254.71,eurox15.3);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= €1.254,71      b=€1255          c=€1.254,71       d=     €1.254,710
```

- “EUROw.d Format” on page 151

FLOATw.d Format

Generates a native single-precision, floating-point value by multiplying a number by 10 raised to the *d*th power.

Category: Numeric

Alignment: Left

Syntax

FLOAT*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Requirement width must be 4

Optional Argument

d

specifies the power of 10 by which to multiply the value.

Default 0

Range 0 – 31

Details

Values that are written by FLOAT4. typically are those meant to be read by some other external program that runs in your operating environment and that expects these single-precision values. If the value that is to be formatted is a missing value, or if it is out-of-range for a native single-precision, floating-point value, a single-precision value of zero is generated.

Example

In the example below, you use the VARBINARY data type in the DECLARE statement to get a hexadecimal representation of a binary number.

Statements	Results [1]
`a=put(1,float4.);`	`0000803F`

1 The result is a hexadecimal representation of a binary number that is stored in IEEE form.

FRACTw. Format

Converts numeric values to fractions.

Category: Numeric

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

FRACT*w*.

Required Argument

w
specifies the width of the output field.

Default 10

Range 4–32

Details

Dividing the number 1 by 3 produces the value 0.33333333. To write this value as 1/3, use the FRACT*w*. format. FRACT*w*. writes fractions in reduced form, that is, 1/2 instead of 50/100.

Example

The following program illustrates the FRACT*w*. format:

```
data _null_;
   declare char(15) a b;
   method run();
      a=put(0.6666666667,fract8.);
      b=put(0.2784,fract8.);
      put a= b=;
   end;
```

```
enddata;
run;
```

SAS writes the following output to the log.

```
a=     2/3        b= 174/625
```

HEXw. Format

Converts real binary (floating-point) values to hexadecimal representation.

Category: Numeric

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

HEX*w*.

Required Argument

w

specifies the width of the output field.

Default 8

Range 1–16

Tip If *w* < 16, the HEX*w*. format converts real binary numbers to fixed-point integers before writing them as hexadecimal characters. It also writes negative numbers in two's complement notation, and right aligns digits. If *w* is 16, HEX*w*. displays floating-point values in their hexadecimal form.

Details

In any operating environment, the least significant byte written by HEX*w*. is the rightmost byte. Some operating environments store integers with the least significant digit as the first byte. The HEX*w*. format produces consistent results in any operating environment regardless of the order of significance by byte.

Note: Different operating environments store floating-point values in different ways. However, the HEX16. format writes hexadecimal representations of floating-point values with consistent results in the same way that your operating environment stores them.

Comparisons

The HEX*w*. numeric format and the $HEX*w*. character format both generate the hexadecimal equivalent of values.

Example

The following program illustrates the HEX*w*. format:

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(35.4, hex8.);
      b=put(88, hex8.);
      c=put(2.33, hex8.);
      d=put(-150, hex8.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=00000023        b=00000058        c=00000002        d=FFFFFF6A
```

See Also

Formats:

- “$HEXw. Format” on page 77

HHMMw.d Format

Writes SAS time values as hours and minutes in the form *hh:mm*.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

HHMM*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 5

Range 2–20

Optional Argument

d

specifies the number of digits to the right of the decimal point in the minutes value. The digits to the right of the decimal point specify a fraction of a minute.

Default 0

Range 0–19

Requirement must be less than *w*

Details

The HHMM*w.d* format writes SAS datetime values in the form *hh:mm*. Here is an explanation of the syntax:

hh

is an integer.

mm

is the number of minutes that range from 00 through 59.

SAS rounds hours and minutes that are based on the value of seconds in a SAS time value.

Comparisons

The HHMM*w.d* format is similar to the TIME*w.d* format except that the HHMM*w.d* format does not print seconds.

The HHMM*w.d* format and the TIME*w.d* format write a leading blank for the single-hour digit. The TOD*w.d* format writes a leading zero for a single-hour digit.

Example

The example table uses the input value of 46796. 46796 is the SAS time value that corresponds to 12:59:56 p.m..

In the first example, SAS rounds up the time value four seconds based on the value of seconds in the SAS time value. In the second example, by adding a decimal specification of 2 to the format shows that fifty-six seconds is 93% of a minute.

```
data _null_;
   declare char(15) a b;
   method run();
      a=put(46796,hhmm.);
      b=put(46796,hhmm8.2);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=13:00          b=12:59.93
```

- “TIME Function” on page 1200

HOURw.d Format

Writes SAS time values as hours and decimal fractions of hours.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

HOUR*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 2

Range 2–20

Optional Argument

d

specifies the number of digits to the right of the decimal point in the hour value. Therefore, SAS prints decimal fractions of the hour.

Range 0-19

Requirement must be less than *w*

Details

SAS rounds hours based on the value of minutes in the SAS time value.

Example

The example table uses the input value of 41400. 41400 is the SAS time value that corresponds to 11:30 AM.

```
data _null_;
   declare char(15) a;
   method run();
      a=put(41400,hour4.1);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=11.5
```

- "SECOND Function" on page 1139
- "TIME Function" on page 1200

IEEEw.d Format

Generates an IEEE floating-point value by multiplying a number by 10 raised to the *d*th power.

Category: Numeric

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

CAUTION: **Large floating-point values and floating-point values that require precision might not be identical to the original SAS value when they are written to an IBM mainframe by using the IEEE format and read back into SAS using the IEEE informat.**

Syntax

IEEE*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 8

Range 3–8

Tip If *w* is 8, an IEEE double-precision, floating-point number is written. If *w* is 5, 6, or 7, an IEEE double-precision, floating-point number is written, which assumes truncation of the appropriate number of bytes. If *w* is 4, an IEEE single-precision floating-point number is written. If *w* is 3, an IEEE single-precision, floating-point number is written, which assumes truncation of one byte.

Optional Argument

d

specifies to multiply the number by 10^d.

Default 0

Range 0–10

Details

This format is useful in operating environments where IEEE*w.d* is the floating-point representation that is used. In addition, you can use the IEEE*w.d* format to create files that are used by programs in operating environments that use the IEEE floating-point representation.

Typically, programs generate IEEE values in single-precision (4 bytes) or double-precision (8 bytes). Programs perform truncation solely to save space on output files. Machine instructions require that the floating-point number be one of the two lengths. The IEEE*w.d* format allows other lengths, which enables you to write data to files that contain space-saving truncated data.

Example

In the following example, you use the VARBINARY data type in the DECLARE statement to produce results that are hexadecimal representations of binary numbers stored in IEEE form.

```
data _null_;
   declare varbinary(8) a;
   declare varchar(15) b;
   method run();
      a=put(1,ieee4.);
      b= put(a,$hex.);
      put b=;
      a=put(1,ieee5.);
      b= put(a,$hex.);
      put b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
b=3F800000
b=3FF0000000
```

JULIANw. Format

Writes SAS date values as Julian dates in the form *yyddd* or *yyyyddd*.

Category: Date and Time

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding

or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

JULIAN*w*.

Required Argument

w
specifies the width of the output field.

Default 5

Range 5–7

Tip If *w* is 5, the JULIAN*w*. format writes the date with a two-digit year. If *w* is 7, the JULIAN*w*. format writes the date with a four-digit year.

Details

The JULIAN*w*. format writes SAS date values in the form *yyddd* or *yyyyddd*. Here is an explanation of the syntax:

yy or *yyyy*
is a two-digit or four-digit integer that represents the year.

ddd
is the number of the day, 1–365 (or 1–366 for leap years), in that year.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017, (the 180th day of the year).

```
data _null_;
   declare char(30) a b;
   method run();
      a=put(20999,julian5.);
      b=put(20999,julian7.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17180                          b=2017180
```

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Functions:

- "DATEJUL Function" on page 501

MDYAMPMw.d Format

Writes datetime values in the form *mm/dd/yy<yy> hh:mm* AM|PM. The year can be either two or four digits.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Notes: The default time period is AM.

Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

MDYAMPM*w*.

Required Argument

w

specifies the width of the output field.

Default 19

Range 8–40

Details

The MDYAMPM*w.d* format writes SAS datetime values in the following form:

mm/*dd*/*yy*[yy] *hh*:*mm*[AM | PM]:

mm
is an integer between 1 and 12 that represents the month.

dd
is an integer between 1 and 31 that represents the day of the month.

yy or *yyyy*
specifies a two-digit or four-digit integer that represents the year.

hh
is an integer between 00 and 23 that represents hours.

mm
is an integer between 00 and 59 that represents minutes.

AM | PM
specifies either the time period 00:01–12:00 noon (PM) or the time period 12:01–12:00 midnight (AM). The default is AM.

date and time separator characters
is one of several special characters, such as the slash (/), colon (:), or a blank character that SAS uses to separate date and time components.

Comparisons

The MDYAMPM*w.* format writes datetime values with separators in the form *mm/dd/yy<yy> hh:mm* AM | PM, and requires a space between the date and the time.

The DATETIME*w.d* format writes datetime values with separators in the form *ddmmmyy<yy>: hh:mm:ss.ss*.

Example

This example uses the input value of 1823167525. 1823167525 is the SAS datetime value that corresponds to 11:25:25 AM on October 9, 2107.

```
data _null_;
   declare char(30) a;
   method run();
      a=put(1823167525,mdyampm18.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=  10/9/17 11:25 AM
```

See Also

Formats:

- “DATETIMEw.d Format” on page 116

MMDDYYw. Format

Writes SAS date values in the form *mmdd<yy>yy* or *mm/dd/<yy>yy*, where a forward slash is the separator and the year appears as either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

MMDDYY*w*.

Required Argument

w

specifies the width of the output field.

Default 8

Range 2–10

Interaction When *w* has a value of from 2 to 5, the date appears with as much of the month and the day as possible. When *w* is 7, the date appears as a two-digit year without slashes.

Details

The MMDDYY*w*. format writes SAS date values in the form *mmdd<yy>yy* or *mm/dd/<yy>yy*. Here is an explanation of the syntax:

mm
is an integer that represents the month.

/
is the separator.

dd
is an integer that represents the day of the month.

<yy>yy
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(20999,mmddyy5.);
      b=put(20999,mmddyy8.);
      c=put(20999,mmddyy8.);
      d=put(20999,mmddyy10.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=06/29          b=06/29/17        c=06/29/17        d=06/29/2017
```

MMDDYYxw. Format

Writes SAS date values in the form *mmdd<yy>yy* or *mm-dd-<yy>yy*, where the *x* in the format name is a character that represents the special character, which separates the month, day, and year. The special character can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

MMDDYY*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the month, the day, and the year. Here are the valid values:

B
separates with a blank

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a slash.

w

specifies the width of the output field.

Default 8

Range 2–10

Interactions When *w* has a value of from 2 to 5, the date appears with as much of the month and the day as possible. When *w* is 7, the date appears as a two-digit year without separators.

When *x* has a value of N, the width range changes to 2–8.

Details

The MMDDYY*xw*. format writes SAS date values in the form *mmdd*<*yy*>*yy* or *mm*X*dd*X<*yy*>*yy*. Here is an explanation of the syntax:

mm
is an integer that represents the month.

X
is a specified separator.

dd
is an integer that represents the day of the month.

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(20999,mmddyyc5.);
      b=put(20999,mmddyyd8.);
      c=put(20999,mmddyyn8.);
      d=put(20999,mmddyyp10.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=06:29          b=06-29-17        c=06292017        d=06.29.2017
```

MMSSw.d Format

Writes SAS time values as the number of minutes and seconds since midnight.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

MMSS*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 5

Range 2–20

Tip Set *w* to a minimum of 5 to write a value that represents minutes and seconds.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the seconds value. Therefore, the SAS time value includes fractional seconds.

Range 0–19

Restriction must be less than *w*

Example

The following program illustrates the MMSS*w*. format:

```
data _null_;
   declare char(15) a;
   method run();
      a=put(4530,mmss.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=75:30
```

MMYYw. Format

Writes SAS date values in the form *mm*M<*yy*>*yy*, where M is the separator and the year appears as either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

MMYY*w*.

Required Argument

w
specifies the width of the output field.

Default 7

Range 5–32

Interaction When *w* has a value of 5 or 6, the date appears with only the last two digits of the year. When *w* is 7 or more, the date appears with a four-digit year.

Details

The MMYY*w*. format writes SAS date values in the form *mm*M<*yy*>*yy*. Here is an explanation of the syntax:

mm
is an integer that represents the month.

M
is the character separator.

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a b c d e;
   method run();
      a=put(20999,mmyy5.);
      b=put(20999,mmyy6.);
      c=put(20999,mmyy.);
      d=put(20999,mmyy7.);
      e=put(20999,mmyy10.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=06M17          b= 06M17          c=06M2017         d=06M2017         e=   06M2017
```

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "MMYYxw. Format" on page 175
- "YYMMw. Format" on page 211

MMYYxw. Format

Writes SAS date values in the form *mm*<*yy*>*yy* or *mm*-<*yy*>*yy*, where the *x* in the format name is a character that represents the special character that separates the month and the year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

MMYY*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the month and the year. Here are the valid values:

C

separates with a colon

D

separates with a hyphen

N

indicates no separator

P

separates with a period

S

separates with a forward slash.

w

specifies the width of the output field.

Default 7

Range 5–32

Interactions When *x* is set to N, no separator is specified. The width range is then 4–32, and the default changes to 6.

When *x* has a value of C, D, P, or S and *w* has a value of 5 or 6, the date appears with only the last two digits of the year. When *w* is 7 or more, the date appears with a four-digit year.

When *x* has a value of *N* and *w* has a value of 4 or 5, the date appears with only the last two digits of the year. When *x* has a value of *N* and *w* is 6 or more, the date appears with a four-digit year.

Details

The MMYY*xw*. format writes SAS date values in the form *mm*<*yy*>*yy* or *mm*X<*yy*>*yy*. Here is an explanation of the syntax:

mm

is an integer that represents the month.

X

is a specified separator.

<*yy*>*yy*

is a two-digit or four-digit integer that represents the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a b c d e;
   method run();
      a=put(20999,mmyyc5.);
      b=put(20999,mmyyd7.);
      c=put(20999,mmyyn4.);
      d=put(20999,mmyyp8.);
      e=put(20999,mmyys10.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=06:17          b=06-2017        c=0617           d= 06.2017       e=   06/2017
```

Formats:

- "MMYYw. Format" on page 174
- "YYMMw. Format" on page 211

MONNAMEw. Format

Writes SAS date values as the name of the month.

Category: Date and Time

Alignment: Right

Syntax

MONNAME*w*.

Required Argument

w

specifies the width of the output field.

Default 9

Range 1–32

Tip Use MONNAME3. to print the first three letters of the month name.

Details

If necessary, SAS truncates the name of the month to fit the format width.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a b c;
   method run();
      a=put(20999,monname1.);
      b=put(20999,monname3.);
      c=put(20999,monname5.);
      put a= b= c=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=J              b=Jun            c= June
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "MONTHw. Format" on page 179

MONTHw. Format

Writes SAS date values as the month of the year.

Category: Date and Time

Alignment: Right

Syntax

MONTH*w*.

Required Argument

w

specifies the width of the output field.

Default 2

Range 1–32

Details

The MONTH*w*. format writes the month (1 through 12) of the year from a SAS date value.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a;
   method run();
      a=put(20999,month.);
      put a= ;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 6
```

Formats:

- "MONNAMEw. Format" on page 177

MONYYw. Format

Writes SAS date values as the month and the year in the form *mmmyy* or *mmmyyyy*.

Category: Date and Time

Alignment: Right

Syntax

MONYY*w*.

Required Argument

w
specifies the width of the output field.

Default 5

Range 5–7

Details

The MONYY*w*. format writes SAS date values in the form *mmmyy* or *mmmyyyy*. Here is an explanation of the syntax:

mmm
is the first three letters of the month name.

yy or *yyyy*
is a two-digit or four-digit integer that represents the year.

Comparisons

The MONYY*w*. format and the DTMONYY*w*. format are similar in that they both write date values. The difference is that MONYY*w*. expects a SAS date value as input, and DTMONYY*w*. expects a datetime value.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to December 24, 2011.

```
data _null_;
   declare char(15) a b;
   method run();
      a=put(20999,monyy5.);
      b=put(20999,monyy7.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=JUN17          b=JUN2017
```

NEGPARENw.d Format

Writes negative numeric values in parentheses.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

NEGPAREN*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 1–32

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0–31

Details

The NEGPAREN*w.d* format attempts to right align output values. If the input value is negative, NEGPAREN*w.d* displays the output by enclosing the value in

parentheses, if the field that you specify is wide enough. Otherwise, it uses a minus sign to represent the negative value. If the input value is nonnegative, NEGPARENw.d displays the value with a leading and trailing blank to ensure proper column alignment. It reserves the last column for a close parenthesis even when the value is positive.

Comparisons

The NEGPARENw.d format is similar to the COMMAw.d format in that it separates every three digits of the value with a comma.

Example

The following program illustrates the NEGPARENw.d format:

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(100,negparen6.);
      b=put(1000,negparen6.);
      c=put(-200,negparen6.);
      d=put(-2000,negparen8.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=  100          b= 1,000          c= (200)          d= (2,000)
```

NENGOw. Format

Writes SAS date values as Japanese dates in the form *e.yymmdd*.

Category: Date and Time

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

NENGO*w*.

Required Argument

w
specifies the width of the output field.

Default 10

Range 2–10

Details

The NENGO*w*. format writes SAS date values in the form *e.yymmdd*. Here is an explanation of the syntax:

e
is the first letter of the name of the imperial era (Meiji, Taisho, Showa, Heisei, or Reiwa).

yy
is an integer that represents the year.

mm
is an integer that represents the month.

dd
is an integer that represents the day of the month.

If the width is too small, SAS omits the period.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2107.

```
data _null_;
   declare char(15) x1 x2 x3 x4 x5;
   method run();
      x1=put(20999,nengo3.);
      x2=put(20999,nengo6.);
      x3=put(20999,nengo8.);
      x4=put(20999,nengo9.);
      x5=put(20999,nengo10.);
      put x1= x2= x3= x4= x5=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
x1=H29              x2=H29/06          x3=H.290629        x4=H29/06/29
x5=H.29/06/29
```

OCTALw. Format

Converts numeric values to octal representation.

Category: Numeric

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

OCTAL*w*.

Required Argument

w

specifies the width of the output field.

Default 3

Range 1–24

Details

If necessary, the OCTAL*w*. format converts numeric values to integers before displaying them in octal representation.

Comparisons

OCTAL*w*. converts numeric values to octal representation. The $OCTAL*w*. format converts character values to octal representation.

Example

The following program illustrates the OCTAL*w*. format:

```
data _null_;
   declare char(15) a;
   method run();
      a=put(3592, octal6.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=007010
```

See Also

Formats:

- "$OCTALw. Format" on page 78

PERCENTw.d Format

Writes numeric values as percentages.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

PERCENT*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 4–32

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than *w*

Details

The PERCENT*w.d* format multiplies values by 100, formats them the same as the BEST*w.d* format, adds a percent sign (%) to the end of the formatted value, and encloses negative values in parentheses. The PERCENT*w.d* format allows room for a percent sign and parentheses, even if the value is not negative.

Example

The following program illustrates the PERCENT*w.d* format:

```
data _null_;
   declare char(15) a b c;
   method run();
      a=put(0.1,percent10.);
      b=put(1.2,percent10.);
      c=put(-.05,percent10.);
      put a= b= c=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=      10%       b=     120%       c=(      5%)
```

See Also

Formats:

- “PERCENTNw.d Format” on page 188

PERCENTNw.d Format

Produces percentages, using a minus sign for negative values.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see “DECIMALCONV= System Option” in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

PERCENTN*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 6

Range 4–32

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range 0–31

Requirement must be less than *w*

Details

The PERCENTN*w.d* format multiplies negative values by 100, formats them the same as the BEST*w.d* format, adds a minus sign to the beginning of the value, and adds a percent sign (%) to the end of the formatted value. The PERCENTN*w.d* format allows room for a percent sign and a minus sign, even if the value is not negative.

Comparisons

The PERCENTN*w.d* format produces percents by using a minus sign instead of parentheses for negative values. The PERCENT*w.d* format produces percents by using parentheses for negative values.

Example

The following program illustrates the PERCENTN*w.d* format:

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(0.1,percentn.);
      b=put(1.2,percentn.);
      c=put(-.05,percentn.);
      d=put(-6.3,percentn.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=  10%          b= 120%          c=  -5%          d=-630%
```

See Also

Formats:

- "PERCENTw.d Format" on page 186

QTRw. Format

Writes SAS date values as the quarter of the year.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

QTR*w*.

Required Argument

w

specifies the width of the output field.

Default 1

Range 1–32

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a;
   method run();
      a=put(20999,qtr.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=2
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

QTRRw. Format

Writes SAS date values as the quarter of the year in Roman numerals.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

QTRR*w*.

Required Argument

w

specifies the width of the output field.

Default 3

Range 3–32

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(15) a;
   method run();
      a=put(20999,qtrr.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= II
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "QTRw. Format" on page 189

ROMANw. Format

Writes numeric values as roman numerals.

Category: Numeric

Alignment: Left

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

ROMAN*w*.

Required Argument

w

specifies the width of the output field.

Default 6

Range 2–32

Details

The ROMAN*w*. format truncates a floating-point value to its integer component before the value is written.

Example

```
data _null_;
   declare char(15) a;
   method run();
      a=put(2017,roman.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=MMXVII
```

TIMEw.d Format

Writes SAS time values as hours, minutes, and seconds in the form *hh:mm:ss.ss*.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

TIME*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 8

Range 2–20

Tip Make *w* large enough to produce the desired results. To obtain a complete time value with three decimal places, you must allow at least

12 spaces: Eight spaces to the left of the decimal point, one space for the decimal point itself, and three spaces for the decimal fraction of seconds.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the seconds value.

Default 0

Range 0–19

Requirement must be less than *w*

Details

The TIME*w.d* format writes SAS time values in the form *hh:mm:ss.ss*. Here is an explanation of the syntax:

hh

is an integer.

Note: If *hh* is a single digit, TIME*w.d* places a leading blank before the digit. For example, the TIME*w.d.* format writes 9:00 instead of 09:00.

mm

is the number of minutes, ranging from 00 through 59.

ss.ss

is the number of seconds, ranging from 00 through 59, with the fraction of a second following the decimal point.

Comparisons

The TIME*w.d* format is similar to the HHMM*w.d* format except that TIME*w.d* includes seconds.

The TIME*w.d* format and the HHMM*w*write a leading blank for a single-hour digit. The TOD*w.d* format writes a leading zero for a single-hour digit.

Example

The example table uses the input value of 59083. 59083 is the SAS time value that corresponds to 4:24:43 PM.

```
data _null_;
   declare varchar(15) a;
   method run();
      a=put(59083, time.);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=16:24:43
```

TIMEAMPMw.d Format

Writes SAS time values as hours, minutes, and seconds in the form *hh:mm:ss.ss* with AM or PM.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—

stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

TIMEAMPM*w*.[*d*]

Required Argument

w
specifies the width of the output field.

Default 11

Range 2–20

Optional Argument

d
specifies the number of digits to the right of the decimal point in the seconds value.

Default 0

Range 0–19

Requirement must be less than *w*

Details

The TIMEAMPM*w.d* format writes SAS time values in the form *hh:mm:ss.ss* with AM or PM. Here is an explanation of the syntax:

hh
is an integer that represents the hour.

mm
is an integer that represents the minutes.

ss.ss
is the number of seconds to two decimal places.

Times greater than 23:59:59 PM appear as the next day.

Make *w* large enough to produce the desired results. To obtain a complete time value with three decimal places and AM or PM, you must allow at least 11 spaces (*hh:mm:ss* PM). If *w* is less than 5, SAS writes AM or PM only.

Comparisons

- The TIMEAMPMM*w.d* format is similar to the TIMEM*w.d* format except, that TIMEAMPMM*w.d* prints AM or PM at the end of the time.
- TIME*w.d* writes hours greater than 23:59:59 PM, and TIMEAMPM*w.d* does not.

Example

The example table uses the input value of 59083. 59083 is the SAS time value that corresponds to 4:24:43 PM.

```
data _null_;
   declare char(15) a b c d;
   method run();
      a=put(59083,timeampm3.);
      b=put(59083,timeampm5.);
      c=put(59083,timeampm7.);
      d=put(59083,timeampm11.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= PM            b= 4 PM          c=4:24 PM        d= 4:24:43 PM
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "TIMEw.d Format" on page 193

TODw.d Format

Writes SAS time values and the time portion of SAS datetime values in the form *hh:mm:ss.ss*.

Category: Date and Time

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more

information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

TOD*w*.[*d*]

Required Argument

w
specifies the width of the output field.

Default 8

Range 2–20

Tip SAS writes a zero for a zero hour if the specified width is sufficient (for example, 02:30 or 00:30).

Optional Argument

d
specifies the number of digits to the right of the decimal point in the seconds value.

Default 0

Range 0–19

Requirement must be less than *w*

Details

The TOD*w.d* format writes SAS datetime values in the form *hh:mm:ss.ss*. Here is an explanation of the syntax:

hh
is an integer that represents the hour.

mm
is an integer that represents the minutes.

ss.ss
is the number of seconds to two decimal places.

Comparisons

The TOD*w.d* format writes a leading zero for a single-hour digit. The TIME*w.d* format and the HHMM*w.d* format write a leading blank for a single-hour digit.

Example

The following program illustrates the TOD*w.d* format:

```
data _null_;
   declare varchar(15) a b;
   method run();
      a=put(1850739623,tod9.);
      put a= ;
      b=put(1472049623, time.);
      put b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 14:20:23
b=  408902
```

Functions:

- "TIMEPART Function" on page 1202

VAXRBw.d Format

Writes real binary (floating-point) data in VMS format.

Category: Numeric

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

VAXRB*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 8

Range 2–8

Optional Argument

d

specifies the power of 10 by which to divide the value.

Default 0

Range 0–31

Details

Use the VAXRB*w.d* format to write data in native VAX/VMS floating-point notation.

Example

In the following example, you use the VARBINARY data type so that the result is the hexadecimal representation for the integer.

```
data _null_;
   declare varbinary(20) a;
   declare varchar(64) b;
   method run();
      a=put(1,vaxrb8.);
      put a=;
      b= put(a, $hex.);
      put b=;
   end;
```

```
enddata;
run;
```

SAS writes the following output to the log.

```
a=
b=8040000000000000
```

w.d Format

Writes standard numeric data one digit per byte.

Category: Numeric

Alignment: Right

Alias: F*w.d*

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

w.[*d*]

Required Argument

w

specifies the width of the output field.

Range 1–32

Tip Allow enough space to write the value, the decimal point, and a minus sign, if necessary.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Range	0–31
Requirement	must be less than *w*
Tip	If *d* is 0 or you omit *d*, *w.d* writes the value without a decimal point.

Details

The *w.d* format rounds to the nearest number that fits in the output field. If *w.d* is too small, SAS might shift the decimal to the BEST*w*. format. The *w.d* format writes negative numbers with leading minus signs. In addition, *w.d* right aligns before writing and pads the output with leading blanks.

Comparisons

The Z*w.d* format is similar to the *w.d* format except that Z*w.d* pads right-aligned output with 0s instead of blanks.

Example

The following program illustrates the *w.d* format:

```
data _null_;
   declare char(20) a;
   method run();
      a=put(23.45, 6.3);
      put a=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=23.450
```

See Also

Formats:

- “Zw.d Format” on page 230

WEEKDATEw. Format

Writes SAS date values as the day of the week and the date in the form *day-of-week*, *month-name dd*, *yy* (or *yyyy*).

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

WEEKDATE*w*.

Required Argument

w
specifies the width of the output field.

Default 29

Range 3–37

Details

The WEEKDATE*w*. format writes SAS date values in the form *day-of-week*, *month-name dd*, *yy* (or *yyyy*). Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

yy or *yyyy*
is a two-digit or four-digit integer that represents the year.

If *w* is too small to write the complete day of the week and month, SAS abbreviates as needed.

Comparisons

The WEEKDATE*w*. format is the same as the WEEKDATX*w*. format except that WEEKDATX*w*. prints *dd* before the month's name.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(30) a b c d;
   method run();
      a=put(20999,weekdate3.);
      b=put(20999,weekdate9.);
      c=put(20999,weekdate15.);
      d=put(20999,weekdate17.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=Thu b= Thursday c=Thu, Jun 29, 17 d=Thu, Jun 29, 2017
```

- "WEEKDAY Function" on page 1273

WEEKDATXw. Format

Writes SAS date values as the day of the week and date in the form *day-of-week*, *dd month-name yy* (or *yyyy*).

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

WEEKDATX*w*.

Required Argument

w
specifies the width of the output field.

Default 29

Range 3–37

Details

The WEEKDATX*w*. format writes SAS date values in the form *day-of-week*, *dd month-name*, *yy* (or *yyyy*). Here is an explanation of the syntax:

dd
is an integer that represents the day of the month.

yy or *yyyy*
is a two-digit or a four-digit integer that represents the year.

If *w* is too small to write the complete day of the week and month, then SAS abbreviates as needed.

Comparisons

The WEEKDATE*w*. format is the same as the WEEKDATX*w*. format, except that WEEKDATE*w*. prints *dd* after the month's name.

The DTWKDATX*w*. format is the same as the WEEKDATX*w*. format, except that DTWKDATX*w*. expects a datetime value as input.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(30) a;
   method run();
      a=put(20999,weekdatx.);
      put a= ;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=       Thursday, 29 June 2017
```

■ “WEEKDAY Function” on page 1273

WEEKDAYw. Format

Writes SAS date values as the day of the week.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

WEEKDAY*w*.

Required Argument

w

specifies the width of the output field.

Default 1

Range 1–32

Details

The WEEKDAY*w*. format writes a SAS date value as the day of the week (where 1=Sunday, 2=Monday, and so on).

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June, 29, 2017.

```
data _null_;
   declare char(20) a;
   method run();
      a=put(20999,weekday.);
      put a= ;
   end;
```

```
enddata;
run;
```

SAS writes the following output to the log.

```
a=5
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "DOWNAMEw. Format" on page 127

YEARw. Format

Writes SAS date values as the year.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

YEAR*w*.

Required Argument

w

specifies the width of the output field.

Default 4

Range 2–32

Tip If *w* is less than 4, the last two digits of the year print. Otherwise, the year value prints as four digits.

Comparisons

The YEAR*w*. format is similar to the DTYEAR*w*. format in that they both write date values. The difference is that YEAR*w*. expects a SAS date value as input, and DTYEAR*w*. expects a SAS datetime value.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(20) a b;
   method run();
      a=put(20999,year2.);
      b=put(20999,year4.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17 b=2017
```

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "DTYEARw. Format" on page 134

YENw.d Format

Writes numeric values with yen signs, commas, and decimal points.

Category: Numeric

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding

or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

YEN*w.d*

Required Arguments

w

specifies the width of the output field.

Default 8

Range 1–32

d

specifies the number of digits to the right of the decimal point in the numeric value.

Restriction must be either 0 or 2

Tip If *d* is 2, then YEN*w.d* writes a decimal point and two decimal digits. If *d* is 0, then YEN*w.d* does not write a decimal point or decimal digits.

Details

The YEN*w.d* format writes numeric values with a leading yen sign and with a comma that separates every three digits of each value.

The hexadecimal representation of the code for the yen sign character is 5B on EBCDIC systems and 5C on ASCII systems. The monetary character these codes represent might be different in other countries.

Example

The following program illustrates the YEN*w.d* format:

```
data _null_;
   declare char(20) a ;
   method run();
      a=put(1254.71,yen10.2);
      put a= ;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= ¥1,254.71
```

YYMMw. Format

Writes SAS date values in the form <*yy*>*yy*M*mm*, where M is a character separator to indicate that the month number follows the M and the year appears as either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

YYMM*w*.

Required Argument

w
specifies the width of the output field.

Default 7

Range 5–32

Interaction When *w* has a value of 5 or 6, the date appears with only the last two digits of the year. When *w* is 7 or more, the date appears with a four-digit year.

Details

The YYMM*w*. format writes SAS date values in the form <*yy*>*yy*M*mm*. Here is an explanation of the syntax:

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

M
is the character separator.

mm
is an integer that represents the month.

Comparisons

- The YYMM*w.d* format is similar to the YYMM*xw.d* format, except the YYMM*xw.d* format contains a separator such as a hyphen, colon, slash, or period between the year and month.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(20) a b c d e ;
   method run();
      a=put(20999,yymm5.);
      b=put(20999,yymm6.);
      c=put(20999,yymm.);
      d=put(20999,yymm7.);
      e=put(20999,yymm10.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17M06 b= 17M06 c=2017M06 d=2017M06 e=   2017M06
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "MMYYw. Format" on page 174
- "YYMMxw. Format" on page 213

YYMMxw. Format

Writes SAS date values in the form <*yy*>*yymm* or <*yy*>*yy-mm*, where the *x* in the format name is a character that represents the special character that separates the year and the month, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

YYMM*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the year and the month. Here are the valid values:

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a forward slash

w

specifies the width of the output field.

Default 7

Range 5–32

Interactions When *x* is set to *N*, no separator is specified. The width range is then 4–32, and the default changes to 6.

When *x* has a value of C, D, P, or S and *w* has a value of 5 or 6, the date appears with only the last two digits of the year. When *w* is 7 or more, the date appears with a four-digit year.

When *x* has a value of *N* and *w* has a value of 4 or 5, the date appears with only the last two digits of the year. When *x* has a value of *N* and *w* is 6 or more, the date appears with a four-digit year.

Details

The YYMM*xw*. format writes SAS date values in the form <*yy*>*yymm* or <*yy*>*yy*X*mm*. Here is an explanation of the syntax:

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

X
is a specified separator.

mm
is an integer that represents the month.

Comparisons

- The YYMM*w.d* format is similar to the YYMM*xw.d* format, except the YYMM*xw.d* format contains a separator such as a hyphen, colon, slash, or period, between the year and month.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(20) a b c d e;
   method run();
      a=put(20999,yymmc5.);
      b=put(20999,yymmd.);
      c=put(20999,yymmn4.);
      d=put(20999,yymmp8.);
      e=put(20999,yymms10.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17:06 b=2017-06 c=1706 d= 2017.06 e=   2017/06
```

See Also

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "MMYYxw. Format" on page 175
- "YYMMw. Format" on page 211

YYMMDDw. Format

Writes SAS date values in the form <*yy*>*yymmdd* or <*yy*>*yy*–*mm*–*dd*, where a hyphen is the separator and the year appears as either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

YYMMDD*w*.

Required Argument

w

specifies the width of the output field.

Default 8

Range 2–10

Interaction When *w* has a value of from 2 to 5, the date appears with as much of the year and the month as possible. When *w* is 7, the date appears as a two-digit year without hyphens.

Details

The YYMMDD*w*. format writes SAS date values in the form <*yy*>*yymmdd* or <*yy*>*yy*–*mm*–*dd*. Here is an explanation of the syntax:

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

–
is the separator.

mm
is an integer that represents the month.

dd
is an integer that represents the day of the month.

Comparisons

- The YYMMDD*w.d* format is similar to the YYMMDD*xw.d* format, except the YYMMDD*xw.d* format contains separators, such as a colon, slash, or period between the year, month, and day.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
ddata _null_;
   declare varchar(20) a b c d e f g h;
   method run();
      a=put(20999,yymmdd2.);
      b=put(20999,yymmdd3.);
      c=put(20999,yymmdd4.);
      d=put(20999,yymmdd5.);
      e=put(20999,yymmdd6.);
      f=put(20999,yymmdd7.);
      g=put(20999,yymmdd8.);
      h=put(20999,yymmdd10.);
      put a= b= c= d= e= f= g= h=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17 b= 17 c=1706 d=17-06 e=170629 f= 170629 g=17-06-29 h=2017-06-29
```

- "YEAR Function" on page 1277

YYMMDDxw. Format

Writes SAS date values in the form <*yy*>*yymmdd* or <*yy*>*yy-mm-dd*, where the *x* in the format name is a character that represents the special character that separates the year, month, and day. The special character can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

YYMMDD*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the year, the month, and the day. Here are the valid values:

B

separates with a blank

C

separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a slash.

w
specifies the width of the output field.

Default 8

Range 2–10

Interactions When *w* has a value of from 2 to 5, the date appears with as much of the year and the month. When *w* is 7, the date appears as a two-digit year without separators.

When *x* has a value of N, the width range is 2–8.

Details

The YYMMDD*xw*. format writes SAS date values in the form <*yy*>*yymmdd* or <*yy*>*yy*X*mm*X*dd*. Here is an explanation of the syntax:

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

X
is a specified separator.

mm
is an integer that represents the month.

dd
is an integer that represents the day of the month.

Comparisons

- The YYMMDD*w*.*d* format is similar to the YYMMDD*xw*.*d* format, but YYMMDD*xw*.*d* format contains a separator between the year and month, such as a colon, slash, or period.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare varchar(20) a b c d;
   method run();
      a=put(20999,yymmddc5.);
      b=put(20999,yymmddd8.);
      c=put(20999,yymmddn8.);
      d=put(20999,yymmddp10.);
      put a= b= c= d=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17:06 b=17-06-29 c=20170629 d=2017.06.29
```

- "MONTH Function" on page 873
- "YEAR Function" on page 1277

YYMONw. Format

Writes SAS date values in the form *yymmm* or *yyyymmm*.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

YYMON*w*.

Required Argument

w
specifies the width of the output field. If the format width is too small to print a four-digit year, only the last two digits of the year are printed.

Default 7

Range 5–32

Details

The YYMON*w*. format abbreviates the month's name to three characters.

Example

The example table uses the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(20) a ;
   method run();
      a=put(20999,yymon.);
      put a= ;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=2017JUN
```

Concepts:

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Formats:

- "MMYYw. Format" on page 174

YYQw. Format

Writes SAS date values in the form <*yy*>*yy*Q*q*, where Q is the separator, the year appears as either 2 or 4 digits, and *q* is the quarter of the year.

Category: Date and Time

Alignment: Right

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

YYQ*w*.

Required Argument

w

specifies the width of the output field.

Default 6

Range 4–32

Interaction When *w* has a value of 4 or 5, the date appears with only the last two digits of the year. When *w* is 6 or more, the date appears with a four-digit year.

Details

The YYQ*w*. format writes SAS date values in the form <*yy*>*yy*Q*q*. Here is an explanation of the syntax:

<yy>yy
is a two-digit or four-digit integer that represents the year.

Q
is the character separator.

q
is an integer (1, 2, 3, or 4) that represents the quarter of the year.

Comparisons

The YYQ*w*. format is similar to the YYQ*xw*. format, but the YYQ*xw*. format has separators between the YY and Q, such as a hyphen, slash, period, or colon.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(20) a b c d e;
   method run();
      a=put(20999,yyq4.);
      b=put(20999,yyq5.);
      c=put(20999,yyq.);
      d=put(20999,yyq6.);
      e=put(20999,yyq10.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17Q2                b= 17Q2               c=2017Q2
d=2017Q2              e=   2017Q2
```

- "YYQRxw. Format" on page 227

■ "YYQZw. Format" on page 229

YYQxw. Format

Writes SAS date values in the form <*yy*>*yyq* or <*yy*>*yy-q*, where the *x* in the format name is a character that represents the special character that separates the year and the quarter of the year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits.

Category: Date and Time

Alignment: Right

Syntax

YYQ*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the year and the quarter. Here are the valid values:

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a forward slash.

w

specifies the width of the output field.

Default 6

Range 4–32

Interactions When *x* is set to *N*, no separator is specified. The width range is then 3–32, and the default changes to 5.

When *w* has a value of 4 or 5, the date appears with only the last two digits of the year. When *w* is 6 or more, the date appears with a four-digit year.

When *x* has a value of *N* and *w* has a value of 3 or 4, the date appears with only the last two digits of the year. When *x* has a value of *N* and *w* is 5 or more, the date appears with a four-digit year.

Details

The YYQ*xw*. format writes SAS date values in the form <*yy*>*yyq* or <*yy*>*yy*X*q*. Here is an explanation of the syntax:

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

X
is a specified separator.

q
is an integer (1, 2, 3, or 4) that represents the quarter of the year.

Comparisons

The YYQ*w*. format is similar to the YYQ*xw*. format, but the YYQ*xw*. format has separators between the YY and Q, such as a hyphen, slash, period, or colon.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(20) a b c d e;
   method run();
      a=put(20999,yyqc4.);
      b=put(20999,yyqd.);
      c=put(20999,yyqn3.);
      d=put(20999,yyqp6.);
      e=put(20999,yyqs8.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=17:2                b=2017-2              c=172
d=2017.2              e= 2017/2
```

- "YYQZw. Format" on page 229

YYQRw. Format

Writes SAS date values in the form <*yy*>*yy*Q*qr*, where Q is the separator, the year appears as either 2 or 4 digits, and *qr* is the quarter of the year expressed in roman numerals.

Category: Date and Time

Alignment: Right

Syntax

YYQR*w*.

Required Argument

w

specifies the width of the output field.

Default 8

Range 6–32

Interaction When the value of *w* is too small to write a four-digit year, the date appears with only the last two digits of the year.

Details

The YYQR*w*. format writes SAS date values in the form <*yy*>*yy*Q*qr*. Here is an explanation of the syntax:

<*yy*>*yy*

is a two-digit or four-digit integer that represents the year.

Q
is the character separator.

qr
is a roman numeral (I, II, III, or IV) that represents the quarter of the year.

Comparisons

The YYQR*w*. format is similar to the YYQR*xw*. format, but the YYQR*xw*. format has separators between the YY and QR, such as a hyphen, slash, period, or colon.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
  declare char(20) a b c d e;
  method run();
     a=put(20999,yyqr6.);
     b=put(20999,yyqr7.);
     c=put(20999,yyqr.);
     d=put(20999,yyqr8.);
     e=put(20999,yyqr10.);
     put a= b= c= d= e=;
  end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 17QII              b=2017QII             c= 2017QII            d=
2017QII
e=  2017QII
```

- "YYQxw. Format" on page 223
- "YYQZw. Format" on page 229

YYQRxw. Format

Writes SAS date values in the form <*yy*>*yyqr* or <*yy*>*yy-qr*, where the *x* in the format name is a character that represents the special character that separates the year and the quarter of the year, which can be a hyphen (–), period (.), blank character, slash (/), colon (:), or no separator; the year can be either 2 or 4 digits and *qr* is the quarter of the year expressed in roman numerals.

Category: Date and Time

Alignment: Right

Syntax

YYQR*xw*.

Required Arguments

x

identifies a separator or specifies that no separator appear between the year and the quarter. Here are the valid values:

C
separates with a colon

D
separates with a hyphen

N
indicates no separator

P
separates with a period

S
separates with a forward slash.

w

specifies the width of the output field.

Default 8

Range 6–32

Interactions When *x* is set to *N*, no separator is specified. The width range is then 5–32, and the default changes to 7.

When the value of *w* is too small to write a four-digit year, the date appears with only the last two digits of the year.

Details

The YYQR*xw*. format writes SAS date values in the form <*yy*>*yyqr* or <*yy*>*yy*X*qr*. Here is an explanation of the syntax:

<*yy*>*yy*
is a two-digit or four-digit integer that represents the year.

X
is a specified separator.

qr
is a roman numeral (I, II, III, or IV) that represents the quarter of the year.

Comparisons

The YYQR*w*. format is similar to the YYQR*xw*. format, but the YYQR*xw*. format has separators between the YY and QR, such as a hyphen, slash, period, or colon.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(20) a b c d e;
   method run();
      a=put(18985,yyqrc6.);
      b=put(20999,yyqrd.);
      c=put(20999,yyqrn5.);
      d=put(20999,yyqrp8.);
      e=put(20999,yyqrs10.);
      put a= b= c= d= e=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a= 11:IV              b= 2017-II            c= 17II
d= 2017.II            e=  2017/II
```

Formats:

- "YYQxw. Format" on page 223
- "YYQRw. Format" on page 225
- "YYQw. Format" on page 221
- "YYQZw. Format" on page 229

YYQZw. Format

Writes SAS date values in the form <*yy*><*qq*>, the year appears as 2 or 4 digits, and *qq* is the quarter of the year.

Category: Date and Time

Alignment: Right

Syntax

YYQZ*w*.

Required Arguments

Z
specifies that no separator appear between the year and the quarter.

w
specifies the width of the output field.

Default 4

Range 4–6

Details

The YYQZ*w*. format writes SAS date values in the form <*yy*> <*qq*>. Here is an explanation of the syntax:

<*yy*>
is a two-digit or four-digit integer that represents the year.

Z
specifies that there is no separator.

<*qq*>
is an integer (01, 02, 03, or 04) that represents the quarter of the year.

Example

The following examples use the input value of 20999. 20999 is the SAS date value that corresponds to June 29, 2017.

```
data _null_;
   declare char(20) a b;
   method run();
      a=put (20999,yyqz6.);
      b=put (20999,yyqz4.);
      put a= b=;
   end;
enddata;
run;
```

SAS writes the following output to the log.

```
a=201702              b=1702
```

- "YYQRxw. Format" on page 227

Zw.d Format

Writes standard numeric data with leading 0s.

Category: Numeric

Alignment: Right

Interaction: When the DECIMALCONV= system option is set to STDIEEE, the output that is written using this format might differ slightly from previous releases. For more information, see "DECIMALCONV= System Option" in *SAS System Options: Reference*.

Note: Beginning in 2025.12, this format supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure that large integer values—stored as BIGINT—are displayed with full precision, up to 19 digits, without rounding

or truncation. BIGINTPROCESSING=YES is recommended for large values that exceed 15–16 digits.

Syntax

Z*w*.[*d*]

Required Argument

w

specifies the width of the output field.

Default 1

Range 1–32

Tip Allow enough space to write the value, the decimal point, and a minus sign, if necessary.

Optional Argument

d

specifies the number of digits to the right of the decimal point in the numeric value.

Default 0

Range 0–31

Tip If *d* is 0 or you omit *d*, Z*w.d* writes the value without a decimal point.

Details

The Z*w.d* format writes standard numeric values one digit per byte and fills in 0s to the left of the data value.

The Z*w.d* format rounds to the nearest number that will fit in the output field. If *w.d* is too large to fit, SAS might shift the decimal to the BESTw. format. The Z*w.d* format writes negative numbers with leading minus signs. In addition, it right aligns before writing and pads the output with leading zeros.

Example

The following program illustrates the Z*w.d* format:

```
data _null_;
   declare char(20) a ;
```

```
      method run();
         a=put(1350,z8.);
         put a= ;
      end;
   enddata;
   run;
```

SAS writes the following output to the log.

```
a=00001350
```

7

DS2 Functions

Overview of DS2 Functions

A **DS2 function** performs a computation or system manipulation on arguments and returns a value. A function expression invokes a function from anywhere in a DS2 program, method, or thread. Most functions use arguments supplied by the user, but a few obtain their arguments from the operating environment.

If the data types of the arguments in the function expression are not what is expected by the DS2 function, DS2 performs a type conversion on the arguments so that they have the appropriate data type. If the type conversion is successful, the function executes. Otherwise, an error is issued. For information, see "DS2 Type Conversions" in *SAS DS2 Programmer's Guide*.

Note: DS2 does not support CALL routines. DS2 functions and methods can alter variable argument values if the return type of the function or method is VOID.

Note: The date and time functions work only with SAS date, time, and datetime values. They do not work with values having the DATE, TIME, and TIMESTAMP data types. For information about working with dates, see "DS2 Expressions" in *SAS DS2 Programmer's Guide*.

General Function Syntax

The syntax of a function has one of the following forms:

function-name (*argument*[, ...*argument*])

function-name (OF *variable-list*)

function-name ([*argument* | OF *variable-list* | OF *array-name*[*]]
[..., [*argument* | OF *variable-list* | OF *array-name*[*]]])

function-name
names the function.

argument
can be a variable name, constant, or any DS2 expression, including another function. The number and type of arguments that DS2 allows are described with individual functions. Multiple arguments are separated by a comma.

Note: If the value of an argument is invalid (for example, missing or outside the prescribed range), an error occurs and the function's return expression is set to a missing or null value.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example Here are examples:

```
x=max(cash,credit);
x=sqrt(1500);
NewCity=left(upcase(City));
x=min(YearTemperature-July,YearTemperature-Dec);
s=repeat('-+.16);
x=min((enroll-drop),(enroll-fail));
if sum(cash,credit)>1000 then put 'Goal reached';
```

variable-list

can be any form of a DS2 variable list, including individual variable names. If more than one variable list appears, separate them with a space or with a comma and another OF.

```
a=sum(of x y z);

z=sum(of y1-y10);

z=msplint(x0,5,of x1-x5,of y1-y5,-2,2);
```

See "OF Operator" on page 2158

"Specifying an Abbreviated Variable List as a Function Argument" in *SAS DS2 Programmer's Guide*

Example The following two examples are equivalent.

```
a=sum(of x1-x10 y1-y10 z1-z10);
a=sum(of x1-x10, of y1-y10, of z1-z10);
```

***array-name*[*]**

names a currently defined array. Specifying an array with an asterisk as a subscript causes DS2 to treat each element of the array as a separate argument.

See "OF Operator" on page 2158

"Specifying a Variable Array as a Function Argument" in *SAS DS2 Programmer's Guide*

Using Functions

Restrictions on Function Arguments

If the value of an argument is invalid, an error occurs and the return expression is set to a missing or null value. Here are some common restrictions on function arguments:

- Some functions require that their arguments be restricted within a certain range. For example, the argument of the LOG function must be greater than 0.
- Most functions do not permit missing or null values as arguments. Exceptions include some of the descriptive statistics functions and financial functions.

  By default when a function argument contains a missing or null value, an error occurs and a message is printed to the SAS log. You can use the MISSING_NOTE option in the DS2_OPTIONS statement to not produce an error and write a note to the SAS log when a function argument contains a missing or null value. For more information, see “DS2_OPTIONS Statement” on page 1363.
- In general, the allowed range of the arguments is platform-dependent, such as with the EXP function.

Data Type Conversion in Functions

The number of arguments and the argument data types that DS2 expects for a function is called the **function signature**. When a function executes, the arguments in the function expression are compared to the function signature. If the arguments and the signature match, the function executes. If the number of arguments do not match, an error occurs.

If the number of arguments match but one or more argument data types do not match, DS2 attempts to convert the argument data types to those of the function signature. If the type conversion is successful, the function executes. Otherwise, an error occurs.

The documentation for each of the functions includes a valid data type for all function arguments. The valid data type is the argument data type that DS2 uses in executing the function. Because DS2 does type conversion, some argument data types in the function expression do not need to be the same as the valid data types for the function argument. For example, if the function expression contains an argument with a data type of INTEGER and the valid data type for that argument is DOUBLE, DS2 converts the data type to DOUBLE when the function executes. Only four data types, VARBINARY and the date/time data types, DATE, TIME,

TIMESTAMP, are non-coercible, meaning that the function expression must contain the valid data type.

Missing and Null Values in DS2 Numeric Functions

For functions that have an input data type of DOUBLE, if a null is passed to the function, the null value is converted to a missing value.

After the function is processed, if the function returns a DOUBLE and if the function returns a missing value, a missing value is returned in SAS mode and a null value is returned in ANSI mode.

For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

Missing and Null Values in DS2 Character Functions

If you pass a character function a null value and the function should return a null value, a null value is returned regardless of whether you are in ANSI mode or SAS mode.

Using a System Expression to Execute a Function

The syntax for a function is similar to the syntax for a method, and when DS2 encounters a method or function expression, it must determine what type of expression it is. If a method expression and a function expression have the same name, DS2 executes the method. The only way to execute a function that has the same name as a method is to use a system expression. A system expression has the following syntax:

`system.`*`function-expression`*

When DS2 encounters a system expression, the call to the method of the same name is bypassed and DS2 calls the function.

Notes on Descriptive Statistic Functions

DS2 provides functions that return descriptive statistics. Except for the MISSING function, the functions correspond to the statistics produced by the MEANS procedure. The computing method for each statistic is discussed in the statistical

procedures section of the *Base SAS Procedures Guide*. SAS calculates descriptive statistics for the non-null or nonmissing values of the arguments.

Notes about Financial Functions

Types of Financial Functions

SAS provides a group of functions that perform financial calculations. The functions are grouped into the following types:

Table 7.1 *Types of Financial Functions*

Function Type	Function	Description
Cash Flow	CONVX, CONVXP	calculates convexities for cash flows
	DUR, DURP	calculates modifies duration for cash flows.
	PVP, YIELDP	calculates present value and yield-to-maturity for a periodic cash flow
General	FINANCE	calculates depreciation, maturation, accrued interest, net present value, periodic savings, and internal rates of return.
Internal rate of return	INTRR, IRR	calculates the internal rate of return
Net present and future value	NETPV, NPV	calculates net present and future values
	SAVINGS	returns the balance of periodic savings by using variable interest rates
Parameter calculations	COMPOUND	calculates compound interest parameters
	MORT	calculates amortization parameters
Pricing	BLKSHCLPRC, BLKSHPTPRC	calculated call prices and put prices for European options on stocks, based on the Black-Scholes model

Function Type	Function	Description
	BLACKCLPRC, BLACKPTPRC	calculates call prices and put prices for European options on futures, based on the Black model
	GARKHCLPRC, GARKHPTPRC	calculates call prices and put prices for European options on stocks, based on the Garman-Kohlhagen model
	MARGRCLPRC, MARGRPTPRC	calculates call options and put prices for European options on stocks, based on the Margrabe model

Using Pricing Functions

A pricing model is used to calculate a theoretical market value (price) for a financial instrument. This value is referred to as a mark-to-market (MtM) value. Typically, a pricing function has the following form:

$$price = function(rf1, rf2, rf3, ...)$$

In the pricing function, *rf1*, *rf2*, and *rf3* are risk factors such as interest rates or foreign exchange rates. The specific values of the risk factors that are used to calculate the MtM value are the base case values. The set of base case values is known as the base case market state.

After determining the MtM value, you can perform the following tasks with the base case values of the risk factors (*rf1*, *rf2*, and *rf3*):

- Set the base case values to specific values to perform scenario analyses.
- Set the base case values to a range of values to perform profit/loss curve analyses and profit/loss surface analyses.
- Automatically set the base case values to different values to calculate sensitivities - that is, to calculate the delta and gamma values of the risk factors.
- Perturb the base case values to create many possible market states so that many possible future prices can be calculated, and simulation analyses can be performed. For Monte Carlo simulation, the values of the risk factors are generated using mathematical models and the copula methodology.

A list of pricing functions and their descriptions is included in "Types of Financial Functions" on page 246.

DS2 Function Examples

```
x=max(cash,credit);
x=sqrt(1500);
NewCity=left(upcase(City));
x=min(YearTemperature-July,YearTemperature-Dec);
s=repeat('----+',16);
x=min((enroll-drop),(enroll-fail));
if sum(cash,credit)>1000 then
   put 'Goal reached';
```

Function Categories

Functions can be categorized by the types of values that they operate on. Each DS2 function belongs to one of the following categories:

Table 7.2 *Function Category Descriptions*

Category	Description
Arithmetic	returns the result of a division that handles special missing values for ODS output See Arithmetic on page 250 for a list of functions.
Array	operates on a named aggregate collection of homogenous data See Array for a list of functions.
Bitwise Logical Operations	operates on one or more bit patterns or binary numbers at the level of their individual bits See Bitwise Logical Operations for a ist of functions.
Character	operates on character data and SQL expressions See Character for a list of functions.
Date and Time	operates on date and time values See Date and Time for a list of functions.

Category	Description
Descriptive Statistics	operates on values that measure central tendency, variation among values, and the shape of distribution values See Descriptive Statistics for a list of functions.
Distance	returns the geodetic distance See Distance for a list of functions.
Error Checking	performs row-level runtime error checking on a thread See Error Checking for a list of functions.
Financial	calculates financial values such as interest, periodic payments, depreciation, and prices for European options on stocks See Financial for a list of functions.
Hyperbolic	performs hyperbolic calculations such as sine, cosine, and tangent See Hyperbolic for a list of functions.
Mathematical	operates on values to perform general mathematical calculations See Mathematical for a list of functions.
Numeric	operates on numeric values See Numeric for a list of functions.
Probability	returns probability calculations See Probability for a list of functions.
Quantile	returns a quantile from specific distributions See Quantile for a list of functions.
Random Number	returns random variates from specific distributions See Random Number for a list of functions.
Special	operates on null values and SAS missing values, suspends execution of a program, specifies numeric informats at run time, and executes a FedSQL statement. See Special for a list of functions.
State and ZIP code	returns ZIP codes, FIPS codes, state and city names, postal codes, and the geodetic distance between ZIP codes. See State and ZIP code for a list of functions.
Trigonometric	operates on values to perform trigonometric calculations See Trigonometric for a list of functions.

Category	Description
Truncation	operates on values to limit the number of digits See Truncation for a list of functions.
Variable Assignment	assigns a data value to a global scalar variable, element of a variable array, or element of a varlist and enables you to get and assign the data values to another variable. See Variable Assignment for a list of functions.
Variable Information	operates on variables and returns names, types, lengths, informats, labels, and other variable information See Variable Information for a list of functions.
Web Tools	encodes and decodes a string of data See Web Tools for a list of functions.

The following table provides brief descriptions of DS2 functions. For more detailed information, see the individual functions.

Category	Language Elements	Description
Arithmetic	DIVIDE Function (p. 525)	Returns the result of a division that handles special missing values for ODS output.
Array	DIM Function (p. 523)	Returns the number of elements in an array.
	HBOUND Function (p. 698)	Returns the upper bound of an array.
	LBOUND Function (p. 810)	Returns the lower bound of an array.
	NDIMS Function (p. 878)	Returns the number of dimensions in an array.
Bitwise Logical Operations	BAND Function (p. 321)	Returns the bitwise logical AND of two arguments.
	BHAMMING_32 Function (p. 325)	Returns the bitwise Hamming distance between two 32-bit integer values.
	BHAMMING_HEX Function (p. 327)	Returns the bitwise Hamming distance between two hexadecimal bit strings.
	BLSHIFT Function (p. 338)	Returns the bitwise logical left shift of two arguments.
	BNOT Function (p. 340)	Returns the bitwise logical NOT of an argument.
	BOR Function (p. 341)	Returns the bitwise logical OR of two arguments.
	BRSHIFT Function (p. 342)	Returns the bitwise logical right shift of two arguments.
	BXOR Function (p. 343)	Returns the bitwise logical EXCLUSIVE OR of two arguments.

Category	Language Elements	Description
CAS	IFN_164 Function (p. 710)	Returns a numeric value based on whether an expression is true, false, or missing.
Character	ANYALNUM Function (p. 277)	Searches a character string for an alphanumeric character, and returns the first character position at which the character is found.
	ANYALPHA Function (p. 280)	Searches a character string for an alphabetic character, and returns the first character position at which the character is found.
	ANYCNTRL Function (p. 283)	Searches a character string for a control character, and returns the first character position at which that character is found.
	ANYDIGIT Function (p. 285)	Searches a character string for a digit, and returns the first character position at which the digit is found.
	ANYFIRST Function (p. 287)	Searches a character string for a character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.
	ANYGRAPH Function (p. 290)	Searches a character string for a graphical character, and returns the first character position at which that character is found.
	ANYLOWER Function (p. 293)	Searches a character string for a lowercase letter, and returns the first character position at which the letter is found.
	ANYNAME Function (p. 295)	Searches a character string for a character that is valid in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.
	ANYPRINT Function (p. 298)	Searches a character string for a printable character, and returns the first character position at which that character is found.
	ANYPUNCT Function (p. 301)	Searches a character string for a punctuation character, and returns the first character position at which that character is found.
	ANYSPACE Function (p. 303)	Searches a character string for a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first character position at which that character is found.
	ANYUPPER Function (p. 306)	Searches a character string for an uppercase letter, and returns the first character position at which the letter is found.
	ANYXDIGIT Function (p. 308)	Searches a character string for a hexadecimal character that represents a digit, and returns the first character position at which that character is found.

Category	Language Elements	Description
	BYTE Function (p. 344)	Returns one character in the ASCII collating sequence.
	CAT Function (p. 346)	Does not remove leading or trailing blanks, and returns a concatenated character string.
	CATQ Function (p. 348)	Concatenates character or numeric values by using a delimiter to separate items and by adding quotation marks to strings that contain the delimiter.
	CATS Function (p. 353)	Removes leading and trailing blanks, and returns a concatenated character string.
	CATT Function (p. 355)	Removes trailing blanks, and returns a concatenated character string.
	CATX Function (p. 358)	Removes leading and trailing blanks, inserts delimiters, and returns a concatenated character string.
	CHOOSEC Function (p. 417)	Returns a character value that represents the results of choosing from a list of arguments.
	CMP Function (p. 422)	Compares two character strings including trailing blanks.
	CMPT Function (p. 424)	Compares two character strings excluding trailing blanks.
	COALESCEC Function (p. 429)	Returns the first non-null or nonmissing value from a list of character arguments.
	COMPARE Function (p. 432)	Returns the position of the leftmost character by which two strings differ, or returns 0 if there is no difference.
	COMPBL Function (p. 436)	Removes multiple blanks from a character string.
	COMPGED Function (p. 444)	Returns the generalized edit distance between two strings.
	COMPLEV Function (p. 451)	Returns the Levenshtein edit distance between two strings.
	COMPRESS Function (p. 456)	Returns a character string with specified characters removed from the original string.
	COUNT Function (p. 476)	Counts the number of times that a specified substring appears within a character string.
	COUNTC Function (p. 479)	Counts the number of characters in a string that appear or do not appear in a list of characters.
	COUNTW Function (p. 483)	Counts the number of words in a character string.
	DEQUOTE Function (p. 507)	Removes matching single quotation marks from a character string that begins with a single quotation mark, and deletes all characters to the right of the closing quotation mark.
	FIND Function (p. 634)	Searches for a specific substring of characters within a character string.

Category	Language Elements	Description
	FINDC Function (p. 637)	Searches a string for any character in a list of characters.
	FINDW Function (p. 646)	Returns the character position of a word in a string, or returns the number of the word in a string.
	INDEX Function (p. 713)	Searches a character expression for a string of characters, and returns the position of the string's first character for the first occurrence of the string.
	INDEXC Function (p. 715)	Searches a character expression for specified characters and returns the position of the first occurrence of any of the characters.
	INDEXW Function (p. 717)	Searches a character expression for a string that is specified as a word, and returns the position of the first character in the word.
	LEFT Function (p. 816)	Left aligns a character expression.
	LENGTH Function (p. 817)	Returns the length of a character string, excluding trailing blanks, in characters.
	LENGTHC Function (p. 819)	Returns the length of a character string, including trailing blanks, in characters.
	LENGTHM Function (p. 822)	Returns the amount of memory, in bytes, that could or might be allocated for a character string.
	LOWCASE Function (p. 843)	Converts all letters in a character expression to lowercase.
	MD5 Function (p. 855)	Returns the result of the message digest of a specified string in binary format.
	NOTALNUM Function (p. 886)	Searches a character string for a non-alphanumeric character, and returns the first character position at which the character is found.
	NOTALPHA Function (p. 888)	Searches a character string for a nonalphabetic character, and returns the first character position at which the character is found.
	NOTCNTRL Function (p. 891)	Searches a character string for a character that is not a control character, and returns the first character position at which that character is found.
	NOTDIGIT Function (p. 893)	Searches a character string for any character that is not a digit, and returns the first character position at which that character is found.
	NOTFIRST Function (p. 896)	Searches a character string for an invalid first character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Category	Language Elements	Description
	NOTGRAPH Function (p. 899)	Searches a character string for a non-graphical character, and returns the first character position at which that character is found.
	NOTLOWER Function (p. 901)	Searches a character string for a character that is not a lowercase letter, and returns the first character position at which that character is found.
	NOTNAME Function (p. 904)	Searches a character string for an invalid character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.
	NOTPRINT Function (p. 906)	Searches a character string for a nonprintable character, and returns the first character position at which that character is found.
	NOTPUNCT Function (p. 909)	Searches a character string for a character that is not a punctuation character, and returns the first character position at which that character is found.
	NOTSPACE Function (p. 912)	Searches a character string for a character that is not a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first character position at which that character is found.
	NOTUPPER Function (p. 915)	Searches a character string for a character that is not an uppercase letter, and returns the first character position at which that character is found.
	NOTXDIGIT Function (p. 917)	Searches a character string for a character that is not a hexadecimal character, and returns the first character position at which that character is found.
	QUOTE Function (p. 1069)	Adds double quotation marks to a character value.
	RANK Function (p. 1094)	Returns the position of a character in the ASCII collating sequence.
	REPEAT Function (p. 1096)	Repeats a character expression.
	REVERSE Function (p. 1097)	Reverses a character expression.
	RIGHT Function (p. 1098)	Right aligns a character expression.
	SCAN Function (p. 1123)	Returns the nth word from a character expression.
	SHA256 Function (p. 1144)	Returns the result of the message digest of a specified string.
	SHA256HEX Function (p. 1146)	Returns the result of the message digest of a specified string and converts the string to hexadecimal representation.

Category	Language Elements	Description
	SHA256HMACHEX Function (p. 1148)	Returns the result of the message digest of a specified string by using the Hash-based Message Authentication (HMAC) algorithm.
	STRIP Function (p. 1179)	Returns a character string with all leading and trailing blanks removed.
	SUBSTR (left of =) Function (p. 1182)	Replaces content in a character variable.
	SUBSTR (right of =) Function (p. 1186)	Extracts a substring from an argument.
	SUBSTRN Function (p. 1189)	Returns a substring, allowing a result with a length of zero.
	TRANSLATE Function (p. 1219)	Replaces specific characters in a character expression.
	TRANSTRN Function (p. 1221)	Replaces or removes all occurrences of a substring in a character string.
	TRANWRD Function (p. 1224)	Replaces all occurrences of a substring in a character string.
	TRIM Function (p. 1230)	Removes trailing blanks from a character expression, and returns a string with a length of zero if the expression is missing.
	UPCASE Function (p. 1237)	Converts all letters in an argument to uppercase.
	VERIFY Function (p. 1246)	Returns the position of the first character that is unique to an expression.
	WHICHC Function (p. 1274)	Returns the first position of a character string from a list of character strings.
Character String Matching	PRXCHANGE Function (p. 1031)	Performs a pattern-matching replacement.
	PRXMATCH Function (p. 1036)	Searches for a pattern match and returns the position at which the pattern is found.
	PRXPAREN Function (p. 1040)	Returns the last bracket match for which there is a match in a pattern.
	PRXPARSE Function (p. 1044)	Compiles a Perl regular expression (PRX) that can be used for pattern matching of a character value.
	PRXPOSN Function (p. 1047)	Returns a character string that contains the value for a capture buffer.
Combinatorial	COMB Function (p. 431)	Computes the number of combinations of n elements taken r at a time.

Category	Language Elements	Description
	LCOMB Function (p. 815)	Computes the logarithm of the COMB function, which is the logarithm of the number of combinations of n objects taken r at a time.
	LFACT Function (p. 825)	Computes the logarithm of the FACT (factorial) function.
	LPERM Function (p. 844)	Computes the logarithm of the number of permutations of n objects, and can include r number of elements.
	PERM Function (p. 981)	Computes the number of permutations of n items that are taken r at a time.
Date and Time	DATDIF Function (p. 496)	Returns the number of days between two dates after computing the difference between the dates according to specified day count conventions.
	DATE Function (p. 500)	Returns the current date as a SAS date value.
	DATEJUL Function (p. 501)	Converts a Julian date to a SAS date value.
	DATEPART Function (p. 503)	Extracts the date from a SAS datetime value.
	DATETIME Function (p. 504)	Returns the current date and time of day as a SAS datetime value.
	DAY Function (p. 505)	Returns the day of the month from a SAS date value.
	DHMS Function (p. 516)	Returns a SAS datetime value from date, hour, minute, and second values.
	HMS Function (p. 700)	Returns a SAS time value from hour, minute, and second values.
	HOLIDAY Function (p. 702)	Returns a SAS date value of a specified holiday for a specified year.
	HOUR Function (p. 707)	Returns the hour from a SAS time or datetime value.
	INTCINDEX Function (p. 727)	Returns the cycle index when a date, time, or timestamp interval and value are specified.
	INTCK Function (p. 731)	Returns the number of interval boundaries of a given kind that lie between two SAS dates, times, or timestamp values encoded as DOUBLE.
	INTCYCLE Function (p. 740)	Returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified.
	INTDT Function (p. 746)	Specifies the number of days to add to a DATE value.
	INTFIT Function (p. 748)	Returns a time interval that is aligned between two dates.

Category	Language Elements	Description
	INTGET Function (p. 750)	Returns a time interval based on three date or datetime values.
	INTINDEX Function (p. 754)	Returns the seasonal index when a date, time, or timestamp interval and value are specified.
	INTNEST Function (p. 761)	Calculates the number of whole periods of the smaller interval that will fit into the period of the larger interval.
	INTNX Function (p. 764)	Increments a SAS date, time, or datetime value encoded as a DOUBLE, and returns a SAS date, time, or datetime value encoded as a DOUBLE.
	INTSEAS Function (p. 777)	Returns the length of the seasonal cycle when a date, time, or datetime interval is specified.
	INTSHIFT Function (p. 781)	Returns the shift interval that corresponds to the base interval.
	INTTEST Function (p. 785)	Returns 1 if a time interval is valid, and returns 0 if a time interval is invalid.
	INTTS Function (p. 788)	Specifies the number of seconds to add to a TIMESTAMP value.
	JULDATE Function (p. 799)	Returns the Julian date from a SAS date value.
	JULDATE7 Function (p. 801)	Returns a seven-digit Julian date from a SAS date value.
	MDY Function (p. 857)	Returns a SAS date value from month, day, and year values.
	MINUTE Function (p. 863)	Returns the minute from a SAS time or datetime value.
	MONTH Function (p. 873)	Returns a number that represents the month from a SAS date value.
	NWKDOM Function (p. 923)	Returns the date for the nth occurrence of a weekday for the specified month and year.
	QTR Function (p. 1063)	Returns the quarter of the year from a SAS date value.
	SECOND Function (p. 1139)	Returns the second from a SAS time or datetime value.
	TIME Function (p. 1200)	Returns the current time of day as a numeric SAS time value.
	TIMEPART Function (p. 1202)	Extracts a time value from a SAS datetime value.
	TO_DATE Function (p. 1210)	Returns a DATE value from a DOUBLE value that specifies a SAS date value.
	TO_DOUBLE Function (p. 1211)	Returns a DOUBLE value that specifies a SAS date, time, or datetime value, from a DATE, TIME, or TIMESTAMP value.

Category	Language Elements	Description
	TO_TIME Function (p. 1215)	Returns a TIME value from a DOUBLE value that specifies a SAS time value.
	TO_TIMESTAMP Function (p. 1216)	Returns a TIMESTAMP value from a DOUBLE value that specifies a SAS time value.
	TODAY Function (p. 1218)	Returns the current date as a numeric SAS date value.
	WEEK Function (p. 1269)	Returns the week-number value.
	WEEKDAY Function (p. 1273)	From a SAS date value, returns a whole number that corresponds to the day of the week.
	YEAR Function (p. 1277)	Returns the year from a SAS date value.
	YRDIF Function (p. 1280)	Returns the difference in years between two dates according to specified day count conventions; returns a person's age.
	YYQ Function (p. 1284)	Returns a SAS date value from year and quarter year values.
Descriptive Statistics	CMISS Function (p. 420)	Counts the number of missing arguments.
	CSS Function (p. 489)	Returns the corrected sum of squares.
	CV Function (p. 494)	Returns the coefficient of variation.
	GEOMEAN Function (p. 683)	Returns the geometric mean.
	GEOMEANZ Function (p. 685)	Returns the geometric mean, using zero fuzzing.
	HARMEAN Function (p. 694)	Returns the harmonic mean.
	HARMEANZ Function (p. 696)	Returns the harmonic mean, using zero fuzzing.
	IQR Function (p. 795)	Returns the interquartile range.
	KURTOSIS Function (p. 802)	Returns the kurtosis.
	LARGEST Function (p. 809)	Returns the kth largest non-null or nonmissing value.
	MAD Function (p. 846)	Returns the median absolute deviation from the median.
	MAX Function (p. 853)	Returns the largest value from a list of arguments.
	MEAN Function (p. 859)	Returns the arithmetic mean (average) of the non-null or nonmissing arguments.
	MEDIAN Function (p. 860)	Returns the median value.

Category	Language Elements	Description
	MIN Function (p. 862)	Returns the smallest value.
	NMISS Function (p. 882)	Returns the number of null and SAS missing numeric values.
	ORDINAL Function (p. 926)	Orders a list of values, and returns a value that is based on a position in the list.
	PCTL Function (p. 927)	Returns the percentile that corresponds to the percentage.
	RANGE Function (p. 1092)	Returns the difference between the largest and the smallest values.
	RMS Function (p. 1100)	Returns the root mean square.
	SKEWNESS Function (p. 1154)	Returns the skewness.
	SMALLEST Function (p. 1157)	Returns the kth smallest non-null or nonmissing value.
	STD Function (p. 1166)	Returns the standard deviation.
	STDERR Function (p. 1167)	Returns the standard error of the mean.
	SUM Function (p. 1194)	Returns the sum of the non-null or nonmissing arguments.
	SUMABS Function (p. 1195)	Returns the sum of the absolute values of the nonmissing arguments.
	USS Function (p. 1242)	Returns the uncorrected sum of squares.
	VAR Function (p. 1245)	Returns the variance.
Distance	GEODIST Function (p. 680)	Returns the geodetic distance between two latitude and longitude coordinates.
	ZIPCITYDISTANCE Function (p. 1289)	Returns the geodetic distance between two ZIP code locations.
Error Checking	GETTHREADERRORSTATUS Function (p. 687)	Gets the runtime error status of the current DS2 thread.
	SETTHREADERRORSTATUS Function (p. 1141)	Sets a user-specified error status value for non-fatal runtime errors, and optionally logs a user-specified message to the SAS log.
Financial	BLACKCLPRC Function (p. 328)	Calculates call prices for European options on futures, based on the Black model.
	BLACKPTPRC Function (p. 331)	Calculates put prices for European options on futures, based on the Black model.
	BLKSHCLPRC Function (p. 333)	Calculates call prices for European options on stocks, based on the Black-Scholes model.

Category	Language Elements	Description
	BLKSHPTPRC Function (p. 336)	Calculates put prices for European options on stocks, based on the Black-Scholes model.
	COMPOUND Function (p. 454)	Returns compound interest parameters.
	CONVX Function (p. 468)	Returns the convexity for an enumerated cash flow.
	CONVXP Function (p. 470)	Returns the convexity for a periodic cash flow stream, such as a bond.
	CUMIPMT Function (p. 490)	Returns the cumulative interest paid on a loan between the start and end period.
	CUMPRINC Function (p. 492)	Returns the cumulative principal paid on a loan between the start and end period.
	DUR Function (p. 527)	Returns the modified duration for an enumerated cash flow.
	DURP Function (p. 528)	Returns the modified duration for a periodic cash flow stream, such as a bond.
	EFFRATE Function (p. 531)	Returns the effective annual interest rate.
	FINANCE Function (p. 539)	Computes financial calculations such as depreciation, maturation, accrued interest, net present value, periodic savings, and internal rates of return.
	FINANCE ACCRINT Function (p. 543)	Computes the accrued interest for a security that pays periodic interest.
	FINANCE ACCRINTM Function (p. 545)	Computes the accrued interest for a security that pays interest at maturity.
	FINANCE AMORDEGRC Function (p. 547)	Computes the depreciation for each accounting period by using a depreciation coefficient.
	FINANCE AMORLINC Function (p. 549)	Computes the depreciation for each accounting period.
	FINANCE COUPDAYBS Function (p. 552)	Computes the number of days from the beginning of the coupon period to the settlement date.
	FINANCE COUPDAYS Function (p. 554)	Computes the number of days in the coupon period that contains the settlement date.
	FINANCE COUPDAYSNC Function (p. 555)	Computes the number of days from the settlement date to the next coupon date.
	FINANCE COUPNCD Function (p. 557)	Computes the next coupon date after the settlement date.
	FINANCE COUPNUM Function (p. 559)	Computes the number of coupons that are payable between the settlement date and the maturity date.

Category	Language Elements	Description
	FINANCE COUPPCD Function (p. 561)	Computes the previous coupon date before the settlement date.
	FINANCE CUMIPMT Function (p. 562)	Computes the cumulative interest paid between two periods.
	FINANCE CUMPRINC Function (p. 564)	Computes the cumulative principal that is paid on a loan between two periods.
	FINANCE DB Function (p. 566)	Computes the depreciation of an asset for a specified period by using the fixed-declining balance method.
	FINANCE DDB Function (p. 567)	Computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.
	FINANCE DISC Function (p. 569)	Computes the discount rate for a security.
	FINANCE DOLLARDE Function (p. 571)	Converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.
	FINANCE DOLLARFR Function (p. 572)	Converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.
	FINANCE DURATION Function (p. 573)	Computes the annual duration of a security with periodic interest payments.
	FINANCE EFFECT Function (p. 575)	Computes the effective annual interest rate.
	FINANCE FV Function (p. 576)	Computes the future value of an investment.
	FINANCE FVSCHEDULE Function (p. 578)	Computes the future value of the initial principal after applying a series of compound interest rates.
	FINANCE INTRATE Function (p. 579)	Computes the interest rate for a fully invested security.
	FINANCE IPMT Function (p. 581)	Computes the interest payment for an investment for a specified period.
	FINANCE IRR Function (p. 582)	Computes the internal rate of return for a series of cash flows.
	FINANCE ISPMT Function (p. 583)	Calculates the interest paid during a specific period of an investment.
	FINANCE MDURATION Function (p. 585)	Computes the Macaulay modified duration for a security with an assumed face value of $100.
	FINANCE MIRR Function (p. 587)	Computes the internal rate of return where positive and negative cash flows are financed at different rates.

Category	Language Elements	Description
	FINANCE NOMINAL Function (p. 588)	Computes the annual nominal interest rates.
	FINANCE NPER Function (p. 589)	Computes the number of periods for an investment.
	FINANCE NPV Function (p. 591)	Computes the net present value of an investment based on a series of periodic cash flows and a discount rate.
	FINANCE ODDFPRICE Function (p. 592)	Computes the price of a security per $100 face value with an odd first period.
	FINANCE ODDFYIELD Function (p. 595)	Computes the yield of a security with an odd first period.
	FINANCE ODDLPRICE Function (p. 597)	Computes the price of a security per $100 face value with an odd last period.
	FINANCE ODDLYIELD Function (p. 599)	Computes the yield of a security with an odd last period.
	FINANCE PMT Function (p. 602)	Computes the periodic payment of an annuity.
	FINANCE PPMT Function (p. 603)	Computes the payment on the principal for an investment for a specified period.
	FINANCE PRICE Function (p. 605)	Computes the price of a security per $100 face value that pays periodic interest.
	FINANCE PRICEDISC Function (p. 607)	Computes the price of a discounted security per $100 face value.
	FINANCE PRICEMAT Function (p. 609)	Computes the price of a security per $100 face value that pays interest at maturity.
	FINANCE PV Function (p. 611)	Computes the present value of an investment.
	FINANCE RATE Function (p. 613)	Computes the interest rate per period of an annuity.
	FINANCE RECEIVED Function (p. 614)	Computes the amount that is received at maturity for a fully invested security.
	FINANCE SLN Function (p. 616)	Computes the straight-line depreciation of an asset for one period.
	FINANCE SYD Function (p. 617)	Computes the sum-of-years digits depreciation of an asset for a specified period.
	FINANCE TBILLEQ Function (p. 619)	Computes the bond-equivalent yield for a treasury bill.

Category	Language Elements	Description
	FINANCE TBILLPRICE Function (p. 620)	Computes the price of a treasury bill per $100 face value.
	FINANCE TBILLYIELD Function (p. 621)	Computes the yield for a treasury bill.
	FINANCE VDB Function (p. 623)	Computes the depreciation of an asset for a specified or partial period by using a declining balance method.
	FINANCE XIRR Function (p. 624)	Computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.
	FINANCE XNPV Function (p. 626)	Computes the net present value for a schedule of cash flows that is not necessarily periodic.
	FINANCE YIELD Function (p. 627)	Computes the yield on a security that pays periodic interest.
	FINANCE YIELDDISC Function (p. 630)	Computes the annual yield for a discounted security (for example, a treasury bill).
	FINANCE YIELDMAT Function (p. 632)	Computes the annual yield of a security that pays interest at maturity.
	GARKHCLPRC Function (p. 673)	Calculates call prices for European options on stocks, based on the Garman-Kohlhagen model.
	GARKHPTPRC Function (p. 675)	Calculates put prices for European options on stocks, based on the Garman-Kohlhagen model.
	INTRR Function (p. 774)	Returns the internal rate of return as a decimal value.
	IPMT Function (p. 792)	Returns the interest payment for a given period for a constant payment loan or the periodic savings for a future balance.
	IRR Function (p. 796)	Returns the internal rate of return as a percentage.
	MARGRCLPRC Function (p. 847)	Calculates call prices for European options on stocks, based on the Margrabe model.
	MARGRPTPRC Function (p. 850)	Calculates put prices for European options on stocks, based on the Margrabe model.
	MORT Function (p. 875)	Returns amortization parameters.
	NETPV Function (p. 880)	Returns the net present value as a percent.
	NOMRATE Function (p. 884)	Returns the nominal annual interest rate.
	NPV Function (p. 920)	Returns the net present value with the rate expressed as a percentage.

Category	Language Elements	Description
	PMT Function (p. 982)	Returns the periodic payment for a constant payment loan or the periodic savings for a future balance.
	PPMT Function (p. 988)	Returns the principal payment for a given period for a constant payment loan or the periodic savings for a future balance.
	PVP Function (p. 1061)	Returns the present value for a periodic cash flow stream (such as a bond), with repayment of principal at maturity.
	SAVING Function (p. 1118)	Returns the future value of a periodic saving.
	SAVINGS Function (p. 1119)	Returns the balance of a periodic savings by using variable interest rates.
	TIMEVALUE Function (p. 1203)	Returns the equivalent of a reference amount at a base date by using variable interest rates.
	YIELDP Function (p. 1278)	Returns the yield-to-maturity for a periodic cash flow stream, such as a bond.
Hyperbolic	ARCOSH Function (p. 312)	Returns the inverse hyperbolic cosine.
	ARSINH Function (p. 315)	Returns the inverse hyperbolic sine.
	ARTANH Function (p. 316)	Returns the inverse hyperbolic tangent.
	SINH Function (p. 1153)	Returns the hyperbolic sine.
	TANH Function (p. 1199)	Returns the hyperbolic tangent.
Installation Information	TSLVL Function (p. 1233)	Provides information about the SAS installation image, including the release number, hot fixes, and maintenance images.
Mathematical	ABS Function (p. 274)	Returns the absolute value of a numeric value expression.
	AIRY Function (p. 276)	Returns the value of the Airy function.
	BETA Function (p. 322)	Returns the value of the beta function.
	CNONCT Function (p. 425)	Returns the noncentrality parameter from a chi-square distribution.
	COALESCE Function (p. 427)	Returns the first non-null or nonmissing value from a list of numeric arguments.
	COMPFUZZ Function (p. 441)	Performs a fuzzy comparison of two numeric values.
	CONSTANT Function (p. 462)	Computes machine and mathematical constants.
	DAIRY Function (p. 495)	Returns the derivative of the AIRY function.

Category	Language Elements	Description
	DEVIANCE Function (p. 512)	Returns the deviance based on a probability distribution.
	DIGAMMA Function (p. 522)	Returns the value of the digamma function.
	ERF Function (p. 532)	Returns the value of the (normal) error function.
	ERFC Function (p. 534)	Returns the value of the complementary (normal) error function.
	EXP Function (p. 535)	Returns the value of the e constant raised to a specified power.
	FACT Function (p. 537)	Computes a factorial.
	FNONCT Function (p. 666)	Returns the value of the noncentrality parameter of an F distribution.
	GAMMA Function (p. 671)	Returns the value of the gamma function.
	GCD Function (p. 678)	Returns the greatest common divisor for a set of integers.
	IBESSEL Function (p. 708)	Returns the value of the modified Bessel function.
	IFN_164 Function (p. 710)	Returns a numeric value based on whether an expression is true, false, or missing.
	JBESSEL Function (p. 798)	Returns the value of the Bessel function.
	LCM Function (p. 813)	Returns the least common multiple for a set of whole numbers.
	LGAMMA Function (p. 826)	Returns the natural logarithm of the Gamma function.
	LOG Function (p. 827)	Returns the natural logarithm (base e) of a numeric value expression.
	LOG10 Function (p. 828)	Returns the base-10 logarithm of a numeric value expression.
	LOG1PX Function (p. 829)	Returns the log of 1 plus the argument.
	LOG2 Function (p. 831)	Returns the base 2 logarithm of a numeric value expression.
	LOGBETA Function (p. 832)	Returns the logarithm of the beta function.
	LOGISTIC Function (p. 836)	Returns the logistic transformation of the argument.
	MOD Function (p. 868)	Returns the remainder from the division of the first argument by the second argument, fuzzed to avoid most unexpected floating-point results.
	MODZ Function (p. 871)	Returns the remainder from the division of the first argument by the second argument, using zero fuzzing.

Category	Language Elements	Description
	POWER Function (p. 986)	Returns the value of a numeric value expression raised to a specified power.
	SIGN Function (p. 1150)	Returns a number that indicates the sign of a numeric value expression.
	SQRT Function (p. 1161)	Returns the square root of a value.
	TNONCT Function (p. 1208)	Returns the value of the noncentrality parameter from the Student's t distribution.
	TRIGAMMA Function (p. 1228)	Returns the value of the trigamma function.
	WHICHN Function (p. 1275)	Returns the first position of a number from a list of numbers.
Numeric	CHOOSEN Function (p. 419)	Returns a numeric value that represents the results of choosing from a list of arguments.
Probability	CDF Function (p. 362)	Computes the left cumulative distribution function from various continuous and discrete probability distributions.
	CDF BERNOULLI Distribution Function (p. 364)	Returns a value from the Bernoulli cumulative probability distribution.
	CDF BETA Distribution Function (p. 366)	Returns a value from the beta cumulative probability distribution.
	CDF BINOMIAL Distribution Function (p. 368)	Returns a value from the binomial cumulative probability distribution.
	CDF CAUCHY Distribution Function (p. 370)	Returns a value from the Cauchy cumulative probability distribution.
	CDF Chi-Square Distribution Function (p. 372)	Returns a value from the chi-square cumulative probability distribution.
	CDF Conway-Maxwell-Poisson Distribution Function (p. 374)	Returns a value from the Conway-Maxwell-Poisson cumulative probability distribution.
	CDF Exponential Distribution Function (p. 376)	Returns a value from the exponential cumulative probability distribution.
	CDF F Distribution Function (p. 378)	Returns a value from the F cumulative probability distribution.
	CDF GAMMA Distribution Function (p. 380)	Returns a value from the gamma cumulative probability distribution.

Category	Language Elements	Description
	CDF Generalized Poisson Distribution Function (p. 382)	Returns a value from the generalized Poisson cumulative probability distribution.
	CDF GEOMETRIC Distribution Function (p. 384)	Returns a value from the geometric cumulative probability distribution.
	CDF HYPERGEOMETRIC Distribution Function (p. 385)	Returns a value from the hypergeometric cumulative probability distribution.
	CDF LAPLACE Distribution Function (p. 388)	Returns a value from the Laplace cumulative probability distribution.
	CDF LOGISTIC Distribution Function (p. 390)	Returns a value from the logistic cumulative probability distribution.
	CDF LOGNORMAL Distribution Function (p. 392)	Returns a value from the lognormal cumulative probability distribution.
	CDF NEGBINOMIAL Distribution Function (p. 394)	Returns a value from the negative binomial cumulative probability distribution.
	CDF NORMAL Distribution Function (p. 396)	Returns a value from the normal cumulative probability distribution.
	CDF NORMALMIX Distribution Function (p. 398)	Returns a value from the normal mixture cumulative probability distribution.
	CDF PARETO Distribution Function (p. 400)	Returns a value from the Pareto cumulative probability distribution.
	CDF POISSON Distribution Function (p. 402)	Returns a value from the Poisson cumulative probability distribution.
	CDF T Distribution Function (p. 404)	Returns a value from the T cumulative probability distribution.
	CDF TWEEDIE Distribution Function (p. 406)	Returns a value from the Tweedie cumulative probability distribution.
	CDF UNIFORM Distribution Function (p. 408)	Returns a value from the uniform cumulative probability distribution.
	CDF WALD (Inverse Gaussian) Distribution Function (p. 410)	Returns a value from the Wald (also known as the inverse Gaussian) cumulative probability distribution.
	CDF WEIBULL Distribution Function (p. 412)	Returns a value from the Weibull cumulative probability distribution.

Category	Language Elements	Description
	LOGCDF Function (p. 834)	Returns the logarithm of a left cumulative distribution function.
	LOGPDF Function (p. 838)	Computes the logarithm of the probability density (mass) function from various continuous and discrete distributions.
	LOGSDF Function (p. 840)	Returns the logarithm of a survival function.
	PDF Function (p. 929)	Returns a value from a probability density (mass) distribution.
	PDF BERNOULLI Distribution Function (p. 932)	Returns a value from the Bernoulli probability density (mass) distribution.
	PDF BETA Distribution Function (p. 934)	Returns a value from the beta probability density (mass) distribution.
	PDF BINOMIAL Distribution Function (p. 936)	Returns a value from the binomial probability density (mass) distribution.
	PDF CAUCHY Distribution Function (p. 938)	Returns a value from the Cauchy probability density (mass) distribution.
	PDF Chi-Square Distribution Function (p. 939)	Returns a value from the chi-square probability density (mass) distribution.
	PDF Conway-Maxwell-Poisson Distribution Function (p. 941)	Returns a value from the Conway-Maxwell-Poisson probability density (mass) distribution.
	PDF EXPONENTIAL Distribution Function (p. 944)	Returns a value from the exponential probability density (mass) distribution.
	PDF F Distribution Function (p. 946)	Returns a value from the F probability density (mass) distribution.
	PDF GAMMA Distribution Function (p. 948)	Returns a value from the gamma probability density (mass) distribution.
	PDF Generalized Poisson Distribution Function (p. 950)	Returns a value from the generalized Poisson probability density (mass) distribution.
	PDF GEOMETRIC Distribution Function (p. 952)	Returns a value from the geometric probability density (mass) distribution.
	PDF Hypergeometric Distribution Function (p. 954)	Returns a value from a hypergeometric probability density (mass) distribution.
	PDF LAPLACE Distribution Function (p. 956)	Returns a value from the Laplace probability density (mass) distribution.

Category	Language Elements	Description
	PDF LOGISTIC Distribution Function (p. 958)	Returns a value from the logistic probability density (mass) distribution.
	PDF LOGNORMAL Distribution Function (p. 960)	Returns a value from the lognormal probability density (mass) distribution.
	PDF NEGBINOMIAL Distribution Function (p. 961)	Returns the value from the negative binomial probability density (mass) distribution.
	PDF NORMAL Distribution Function (p. 963)	Returns a value from the normal probability density (mass) distribution.
	PDF NORMALMIX Distribution Function (p. 965)	Returns a value from the normal mixture probability density (mass) distribution.
	PDF PARETO Distribution Function (p. 967)	Returns a value from the Pareto probability density (mass) distribution.
	PDF POISSON Distribution Function (p. 969)	Returns a value from the Poisson probability density (mass) distribution.
	PDF T Distribution Function (p. 971)	Returns a value from the T probability density (mass) distribution.
	PDF TWEEDIE Distribution Function (p. 973)	Returns a value from the Tweedie probability density (mass) distribution.
	PDF UNIFORM Distribution Function (p. 975)	Returns a value from the uniform probability density (mass) distribution.
	PDF Wald (Inverse Gaussian) Distribution Function (p. 977)	Returns a value from the Wald (also known as the inverse Gaussian) probability density (mass) distribution.
	PDF WEIBULL Distribution Function (p. 979)	Returns a value from the Weibull probability density (mass) distribution.
	POISSON Function (p. 985)	Returns the probability from a Poisson distribution.
	PROBBETA Function (p. 990)	Returns the probability from a beta distribution.
	PROBBNML Function (p. 991)	Returns the probability from a binomial distribution.
	PROBBNRM Function (p. 993)	Returns a probability from a bivariate normal distribution.
	PROBCHI Function (p. 994)	Returns the probability from a chi-square distribution.
	PROBDF Function (p. 995)	Calculates significance probabilities for Dickey-Fuller tests for unit roots in time series.

Category	Language Elements	Description
	PROBF Function (p. 1002)	Returns the probability from an F distribution.
	PROBGAM Function (p. 1004)	Returns the probability from a gamma distribution.
	PROBHYPR Function (p. 1005)	Returns the probability from a hypergeometric distribution.
	PROBMC Function (p. 1008)	Returns a probability or a quantile from various distributions for multiple comparisons of means.
	PROBMED Function (p. 1020)	Computes cumulative probabilities for the sample median.
	PROBNEGB Function (p. 1021)	Returns the probability from a negative binomial distribution.
	PROBNORM Function (p. 1023)	Returns the probability from the standard normal distribution.
	PROBT Function (p. 1024)	Returns the probability from a t distribution.
	SDF Function (p. 1133)	Returns a survival function.
Quantile	BETAINV Function (p. 324)	Returns a quantile from the beta distribution.
	GAMINV Function (p. 670)	Returns a quantile from the gamma distribution.
	PROBIT Function (p. 1007)	Returns a quantile from the standard normal distribution.
	QUANTILE Function (p. 1064)	Returns the quantile from a distribution when you specify the left probability (CDF).
	SQUANTILE Function (p. 1162)	Returns the quantile from a distribution when you specify the right probability (SDF).
	TINV Function (p. 1206)	Returns a quantile from the t distribution.
Random Number	RAND Function (p. 1071)	Generates random numbers from a distribution that you specify.
	STREAMINIT Function (p. 1173)	Specifies a random-number generator and seed value for generating random numbers.
Special	DIF Function (p. 519)	Returns differences between an argument and its nth lag.
	FMTINFO Function (p. 663)	Returns information about a SAS format or informat.
	INPUTC Function (p. 719)	Enables you to specify a character informat at run time.
	INPUTN Function (p. 721)	Enables you to specify a numeric informat at run time.
	INPUTN_164 Function (p. 723)	Specifies a numeric informat at run time.

Category	Language Elements	Description
	LAG Function (p. 804)	Returns values from a queue.
	MISSING Function (p. 865)	Returns a number that indicates whether the argument contains a missing value.
	N Function (p. 877)	Returns the number of non-null or nonmissing numeric values.
	NULL Function (p. 921)	Returns a 1 if the argument is null and a 0 if the argument is not null.
	PROGRAMBLOCKLINENUMBER Function (p. 1025)	Returns the line number of the current statement starting from the beginning of the current program block.
	PROGRAMBLOCKLNAME Function (p. 1027)	Returns the name of the current programming block.
	PROGRAMBLOCKTYPE Function (p. 1029)	Returns the type of the current programming block.
	PUT Function (p. 1051)	Returns a value using a specified format.
	PUTC Function (p. 1054)	Enables you to specify a character format at run time.
	PUTN Function (p. 1058)	Enables you to specify a numeric format at run time.
	SASLOGLINENUMBER Function (p. 1116)	Returns the line number of the current statement in the SAS log.
	SLEEP Function (p. 1155)	For a specified period of time, suspends the execution of a program that invokes this function.
	SQLEXEC Function (p. 1159)	Executes a FedSQL statement to create, delete, or update a table or to insert rows into a table.
	SYSGET Function (p. 1197)	Returns the value of the specified operating-environment variable .
	UUIDGEN Function (p. 1244)	Returns the short form of a Universally Unique Identifier (UUID).
State and ZIP code	FIPNAME Function (p. 654)	Converts two-digit FIPS codes to uppercase state names.
	FIPNAMEL Function (p. 656)	Converts two-digit FIPS codes to mixed case state names.
	FIPSTATE Function (p. 658)	Converts two-digit FIPS codes to two-character state postal codes.
	STFIPS Function (p. 1169)	Converts state postal codes to FIPS state codes.
	STNAME Function (p. 1170)	Converts state postal codes to uppercase state names.
	STNAMEL Function (p. 1172)	Converts state postal codes to mixed case state names.

Category	Language Elements	Description
	ZIPCITY Function (p. 1286)	Returns a city name and the two-character postal code that corresponds to a ZIP code.
	ZIPCITYDISTANCE Function (p. 1289)	Returns the geodetic distance between two ZIP code locations.
	ZIPFIPS Function (p. 1290)	Converts ZIP codes to two-digit FIPS codes.
	ZIPNAME Function (p. 1292)	Converts ZIP codes to uppercase state names.
	ZIPNAMEL Function (p. 1294)	Converts ZIP codes to mixed-case state names.
	ZIPSTATE Function (p. 1295)	Converts ZIP codes to two-character state postal codes.
Trigonometric	ARCOS Function (p. 311)	Returns the arccosine in radians.
	ARSIN Function (p. 313)	Returns the arcsine in radians.
	ATAN Function (p. 318)	Returns the arctangent in radians.
	ATAN2 Function (p. 319)	Returns the arctangent of the x and y coordinates of a right triangle, in radians.
	COS Function (p. 472)	Returns the cosine in radians.
	COSH Function (p. 473)	Returns the hyperbolic cosine in radians.
	COT Function (p. 474)	Returns the cotangent.
	CSC Function (p. 487)	Returns the cosecant.
	SEC Function (p. 1137)	Returns the secant.
	SIN Function (p. 1152)	Returns the trigonometric sine.
	TAN Function (p. 1198)	Returns the tangent.
Truncation	CEIL Function (p. 414)	Returns the smallest integer greater than or equal to a numeric value expression.
	CEILZ Function (p. 416)	Returns the smallest integer that is greater than or equal to the argument, using zero fuzzing.
	FLOOR Function (p. 659)	Returns the largest integer less than or equal to a numeric value expression.
	FLOORZ Function (p. 662)	Returns the largest integer that is less than or equal to the argument, using zero fuzzing.
	FUZZ Function (p. 668)	Returns the nearest whole number if the argument is within 1E-12 of that number.

Category	Language Elements	Description
	INT Function (p. 725)	Returns the whole number, fuzzed to avoid unexpected floating-point results.
	INTZ Function (p. 790)	Returns the whole number portion of the argument, using zero fuzzing.
	ROUND Function (p. 1101)	Rounds the first argument to the nearest multiple of the second argument, or to the nearest integer when the second argument is omitted.
	ROUNDE Function (p. 1110)	Rounds the first argument to the nearest multiple of the second argument, and returns an even multiple when the first argument is halfway between the two nearest multiples.
	ROUNDZ Function (p. 1113)	Rounds the first argument to the nearest multiple of the second argument, using zero fuzzing.
	TRUNC Function (p. 1232)	Truncates a numeric value to a specified length.
Variable Assignment	VGETVALUE Function (p. 1250)	Gets the value of the specified variable and assigns it to another variable.
	VSETMISSING Function (p. 1262)	Assigns a missing or null value to the specified variable or variables.
	VSETVALUE Function (p. 1265)	Sets a variable to a specified value.
Variable Information	VFORMAT Function (p. 1248)	Returns the format that is associated with the specified global variable.
	VINARRAY Function (p. 1252)	Returns a value that indicates whether the specified variable is a member of an array.
	VINFORMAT Function (p. 1254)	Returns the informat that is associated with the specified variable.
	VLABEL Function (p. 1256)	Returns the label that is associated with the specified variable.
	VLENGTH Function (p. 1258)	Returns the size of the specified variable.
	VNAME Function (p. 1260)	Returns the name of the specified variable.
	VTYPE Function (p. 1267)	Returns the full name of the data type that is associated with a variable.
Web Tools	URLDECODE Function (p. 1239)	Returns a string that was decoded using the URL escape syntax.
	URLENCODE Function (p. 1240)	Returns a string that was encoded using the URL escape syntax.

Dictionary

ABS Function

Returns the absolute value of a numeric value expression.

Category: Mathematical

Returned data type: BIGINT, DECIMAL, DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

ABS(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type: BIGINT, DECIMAL, DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If the result is a number that does not fit into the range of the argument's data type, the ABS function fails.

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Examples

Example 1: Absolute Value of a DECIMAL and Negative Number

The following program illustrates the absolute value of a DECIMAL and a negative number:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method run();
      x=abs(2.4);
      y=abs(-3);
      put x= y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=2.4 y=3
```

Example 2: Absolute Value of a Mathematical Expression

The following program illustrates the absolute value of a simple, mathematical expression.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double z;
   method run();
      z=abs((3 * 50.5) / 5);
      put z=;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
z=30.3
```

AIRY Function

Returns the value of the Airy function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

AIRY(*x*)

Required Argument

x

specifies a numeric constant, variable, or expression.

Data type DOUBLE

Details

The AIRY function returns the value of the Airy function. (See a list of References.) It is the solution of the differential equation

$$w^{(2)} - xw = 0$$

with the conditions

$$w(0) = \frac{1}{3^{\frac{2}{3}}\Gamma\left(\frac{2}{3}\right)}$$

and

$$w'(0) = -\frac{1}{3^{\frac{1}{3}}\Gamma\left(\frac{1}{3}\right)}$$

Example

The following program illustrates the AIRY function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      x=airy(2.0);
      y=airy(-2.0);
      put x= y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0.03492413042327 y=0.22740742820168
```

ANYALNUM Function

Searches a character string for an alphanumeric character, and returns the first character position at which the character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYALNUM('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYALNUM function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYALNUM function searches a string for the first occurrence of any character that is a digit or an uppercase or lowercase letter. If such a character is found, ANYALNUM returns the position in the string of that character. If no such character is found, ANYALNUM returns a value of 0.

If you use only one argument, ANYALNUM begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYALNUM returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYALNUM function searches a character string for an alphanumeric character. The NOTALNUM function searches a character string for a non-alphanumeric character.

Examples

Example 1: Scanning a String from Left to Right

The following program uses the ANYALNUM function to search a string from left to right for alphanumeric characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data ltrtest;
   dcl char(15) string c;
   dcl double j;
```

```
   method run();
      string='Next = Last + 1';
      j=0;
      do until (j=0);
         j=anyalnum(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=8 c=L
j=9 c=a
j=10 c=s
j=11 c=t
j=15 c=1
The end
```

Example 2: Scanning a String from Right to Left

The following program uses the ANYALNUM function to search a string from right to left for alphanumeric characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data rtltest;
   dcl char(15) string c;
   dcl double j;
   method run();
      string='Next = Last + 1;';
      j=999999;
      do until(j=0);
         j=anyalnum(string, 1-j);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
         put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=15 c=1
j=11 c=t
j=10 c=s
j=9 c=a
j=8 c=L
j=4 c=t
j=3 c=x
j=2 c=e
j=1 c=N
The end
```

ANYALPHA Function

Searches a character string for an alphabetic character, and returns the first character position at which the character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYALPHA('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYALPHA function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYALPHA function searches a string for the first occurrence of any character that is an uppercase or lowercase letter. If such a character is found, ANYALPHA returns the position in the string of that character. If no such character is found, ANYALPHA returns a value of 0.

If you use only one argument, ANYALPHA begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYALPHA returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYALPHA function searches a character string for an alphabetic character. The NOTALPHA function searches a character string for a non-alphabetic character.

Examples

Example 1: Searching a String for Alphabetic Characters from Left to Right

The following program uses the ANYALPHA function to search a string from left to right for alphabetic characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyalpha(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=9 c=n
j=16 c=E
The end
```

Example 2: Identifying Alphabetic Characters By Using the ANYALPHA Function

You can execute the following program to show the alphabetic characters that are identified by the ANYALPHA function.

Note: This program works only for single-byte encodings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testany;
   dcl nchar(3) byte1 hex1;
   dcl double dec anyalpha1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         anyalpha1=anyalpha(byte1);
         output;
```

```
      end;
   end;
enddata;
run;
quit;

proc print data=testany;
run;
```

ANYCNTRL Function

Searches a character string for a control character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYCNTRL('*expression*' [, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYCNTRL function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYCNTRL function searches a string for the first occurrence of a control character. If such a character is found, ANYCNTRL returns the position in the string of that character. If no such character is found, ANYCNTRL returns a value of 0.

If you use only one argument, ANYCNTRL begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYCNTRL returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYCNTRL function searches a character string for a control character. The NOTCNTRL function searches a character string for a character that is not a control character.

Example

You can execute the following program to show the control characters that are identified by the ANYCNTRL function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testany (overwrite=yes);
   dcl nchar(3) byte1 hex1;
```

```
   dcl double dec anycntrl1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         anycntrl1=anycntrl(byte1);
         if anycntrl1 then output;
      end;
   end;
enddata;
run;
quit;

proc print data=testany;
run;
```

ANYDIGIT Function

Searches a character string for a digit, and returns the first character position at which the digit is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYDIGIT('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The ANYDIGIT function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYDIGIT function searches a string for the first occurrence of any character that is a digit. If such a character is found, ANYDIGIT returns the position in the string of that character. If no such character is found, ANYDIGIT returns a value of 0.

If you use only one argument, ANYDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYDIGIT function searches a character string for a digit. The NOTDIGIT function searches a character string for any character that is not a digit.

Example

The following program uses the ANYDIGIT function to search for a character that is a digit.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anydigit(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=14 c=1
j=15 c=2
j=17 c=3
The end
```

ANYFIRST Function

Searches a character string for a character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

ANYFIRST('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The ANYFIRST function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7. These characters are the underscore (_) and uppercase or lowercase English letters. If such a character is found, ANYFIRST returns the position in the string of that character. If no such character is found, ANYFIRST returns a value of 0.

If you use only one argument, ANYFIRST begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYFIRST returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7. The NOTFIRST function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7.

Example

The following program uses the ANYFIRST function to search a string for any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyfirst(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=8 c=_
j=9 c=n
j=10 c=_
j=16 c=E
The end
```

ANYGRAPH Function

Searches a character string for a graphical character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYGRAPH('*string*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYGRAPH function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYGRAPH function searches a string for the first occurrence of a graphical character. A graphical character is defined as any printable character other than white space. If such a character is found, ANYGRAPH returns the position in the string of that character. If no such character is found, ANYGRAPH returns a value of 0.

If you use only one argument, ANYGRAPH begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYGRAPH returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYGRAPH function searches a character string for a graphical character. The NOTGRAPH function searches a character string for a non-graphical character.

Examples

Example 1: Searching a String for Graphical Characters

The following program uses the ANYGRAPH function to search a string for graphical characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anygraph(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
```

```
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=6 c==
j=8 c=_
j=9 c=n
j=10 c=_
j=12 c=+
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end
```

Example 2: Identifying Control Characters By Using the ANYGRAPH Function

You can execute the following program to show the control characters that are identified by the ANYGRAPH function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testany (overwrite=yes);
   dcl nchar(3) byte1 hex1;
   dcl double dec anygraph1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         anygraph=anygraph(byte1);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=testany;
run;
```

ANYLOWER Function

Searches a character string for a lowercase letter, and returns the first character position at which the letter is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYLOWER('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYLOWER function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYLOWER function searches a string for the first occurrence of a lowercase letter. If such a character is found, ANYLOWER returns the position in the string of that character. If no such character is found, ANYLOWER returns a value of 0.

If you use only one argument, ANYLOWER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYLOWER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYLOWER function searches a character string for a lowercase letter. The NOTLOWER function searches a character string for a character that is not a lowercase letter.

Example

The following program uses the ANYLOWER function to search a string for any character that is a lowercase letter.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anylower(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
j=2 c=e
j=3 c=x
j=4 c=t
j=9 c=n
The end
```

ANYNAME Function

Searches a character string for a character that is valid in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYNAME('*expression*'[,*start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, VARCHAR, NVARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The ANYNAME function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7. These characters are the underscore (_), digits, and uppercase or lowercase English letters. If such a character is found, ANYNAME returns the position in the string of that character. If no such character is found, ANYNAME returns a value of 0.

If you use only one argument, ANYNAME begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYNAME returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7. The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7.

Example

The following program uses the ANYNAME function to search a string for any character that is valid in a SAS variable name under VALIDVARNAME=V7.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyname(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=8 c=_
j=9 c=n
j=10 c=_
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
The end
```

ANYPRINT Function

Searches a character string for a printable character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYPRINT('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYPRINT function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYPRINT function searches a string for the first occurrence of a printable character. If such a character is found, ANYPRINT returns the position in the string of that character. If no such character is found, ANYPRINT returns a value of 0.

If you use only one argument, ANYPRINT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*,

specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYPRINT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYPRINT function searches a character string for a printable character. The NOTPRINT function searches a character string for a non-printable character.

Examples

Example 1: Searching a String for a Printable Character

The following program uses the ANYPRINT function to search a string for printable characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyprint(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=9 c=n
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end
```

Example 2: Identifying Control Characters By Using the ANYPRINT Function

You can execute the following program to show the control characters that are identified by the ANYPRINT function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testany (overwrite=yes);
   dcl nchar(3) byte1 hex1;
   dcl double dec anyprint1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         anyprint1=anyprint(byte1);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=testany;
run;
```

ANYPUNCT Function

Searches a character string for a punctuation character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYPUNCT('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYPUNCT function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYPUNCT function searches a string for the first occurrence of a punctuation character. If such a character is found, ANYPUNCT returns the position in the string of that character. If no such character is found, ANYPUNCT returns a value of 0.

If you use only one argument, ANYPUNCT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*,

specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYPUNCT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYPUNCT function searches a character string for a punctuation character. The NOTPUNCT function searches a character string for a character that is not a punctuation character.

Examples

Example 1: Searching a String for Punctuation Characters

The following program uses the ANYPUNCT function to search a string for punctuation characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anypunct(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=8 c=_
j=10 c=_
j=18 c=;
The end
```

Example 2: Identifying Control Characters By Using the ANYPUNCT Function

You can execute the following program to show the control characters that are identified by the ANYPUNCT function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testany (overwrite=yes);
   dcl nchar(3) byte1 hex1;
   dcl double dec anypunct1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         anypunct1=anypunct(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

ANYSPACE Function

Searches a character string for a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

ANYSPACE('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYSPACE function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYSPACE function searches a string for the first occurrence of any character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. If such a character is found, ANYSPACE returns the position in the string of that character. If no such character is found, ANYSPACE returns a value of 0.

If you use only one argument, ANYSPACE begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYSPACE returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYSPACE function searches a character string for the first occurrence of a character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. The NOTSPACE function searches a character string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed.

Examples

Example 1: Searching a String for a Whitespace Character

The following program uses the ANYSPACE function to search a string for a character that is a whitespace character.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyspace(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=5 c=
j=7 c=
j=11 c=
j=13 c=
The end
```

Example 2: Identifying Control Characters By Using the ANYSPACE Function

You can execute the following program to show the control characters that are identified by the ANYSPACE function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testany (overwrite=yes);
   dcl nchar(3) byte1 hex1;
   dcl double dec anyspace1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         anyspace1=anyspace(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

ANYUPPER Function

Searches a character string for an uppercase letter, and returns the first character position at which the letter is found.

Category: Character

Returned data type: DOUBLE

Syntax

ANYUPPER('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the ANYUPPER function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The ANYUPPER function searches a string for the first occurrence of an uppercase letter. If such a character is found, ANYUPPER returns the position in the string of that character. If no such character is found, ANYUPPER returns a value of 0.

If you use only one argument, ANYUPPER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYUPPER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYUPPER function searches a character string for an uppercase letter. The NOTUPPER function searches a character string for a character that is not an uppercase letter.

Example

The following program uses the ANYUPPER function to search a string for an uppercase letter.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyupper(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=16 c=E
The end
```

- “NOTUPPER Function” on page 915

ANYXDIGIT Function

Searches a character string for a hexadecimal character that represents a digit, and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

ANYXDIGIT('*expression*'[,*start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The ANYXDIGIT function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The ANYXDIGIT function searches a string for the first occurrence of any character that is a digit or an uppercase or lowercase A, B, C, D, E, or F. If such a character is found, ANYXDIGIT returns the position in the string of that character. If no such character is found, ANYXDIGIT returns a value of 0.

If you use only one argument, ANYXDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

ANYXDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The ANYXDIGIT function searches a character string for a character that is a hexadecimal character. The NOTXDIGIT function searches a character string for a character that is not a hexadecimal character.

Example

The following program uses the ANYXDIGIT function to search a string for a hexadecimal character that represents a digit.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=anyxdigit(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
j=2 c=e
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
The end
```

ARCOS Function

Returns the arccosine in radians.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

ARCOS(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Range –1 to 1

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ARCOS function returns the arccosine (inverse cosine) of the argument. The value that is returned is specified in radians.

Example

The following program illustrates the ARCOS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c;
   method run();
      a=arcos(1);
      b=arcos(0);
      c=arcos(-.5);
      put 'a=' a;
```

```
        put 'b=' b;
        put 'c=' c;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 0
b= 1.57079632679489
c= 2.09439510239319
```

ARCOSH Function

Returns the inverse hyperbolic cosine.

Category: Hyperbolic

Returned data type: DOUBLE

Syntax

ARCOSH(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Range *expression* >= 1

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ARCOSH function computes the inverse hyperbolic cosine. The ARCOSH function is mathematically defined by the following equation, where *expression* >= 1. In the equation, *expression* is represented by *x*.

$$ARCOSH(x) = log\left(x + \sqrt{x^2 - 1}\right)$$

Example

The following program illustrates the ARCOSH function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=arcosh(5);
      b=arcosh(13);
      put 'a=' a;
      put 'b=' b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 2.29243166956117
b= 3.25661395480005
```

ARSIN Function

Returns the arcsine in radians.

Category:	Trigonometric
Returned data type:	DOUBLE

Syntax

ARSIN(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Range –1 to 1

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ARSIN function returns the arcsine (inverse sine) of the argument. The value that is returned is specified in radians.

Example

The following program illustrates the ARSIN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c;
   method run();
      a=arsin(0);
      b=arsin(1);
      c=arsin(-0.5);
      put 'a=' a;
      put 'b=' b;
      put 'c=' c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 0
b= 1.57079632679489
c= -0.52359877559829
```

ARSINH Function

Returns the inverse hyperbolic sine.

Category: Hyperbolic

Returned data type: DOUBLE

Syntax

ARSINH(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Range $-\infty < x < \infty$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ARSINH function computes the inverse hyperbolic sine. The ARSINH function is mathematically defined by the following equation, where $-\infty < x < \infty$.

$$ARSINH(x) = log\left(x + \sqrt{x^2 + 1}\right)$$

Replace the infinity symbol with the largest double precision number that is available on your machine. In the equation, *expression* is represented by *x*.

Example

The following program illustrates the ARSINH function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b ;
```

```
      method run();
         a=arsinh(5);
         b=arsinh(-5);
         put 'a=' a;
         put 'b=' b;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log.

```
a= 2.31243834127275
b= -2.31243834127275
```

ARTANH Function

Returns the inverse hyperbolic tangent.

Category:	Hyperbolic
Returned data type:	DOUBLE

Syntax

ARTANH(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Range –1 < *expression* < 1

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ARTANH function computes the inverse hyperbolic tangent. The ARTANH function is mathematically defined by the following equation, where –1 < *expression*< 1. In the equation, *expression* is represented by *x*.

$$ARTANH(x) = \frac{1}{2} log\left(\frac{1+x}{1-x}\right)$$

Example

The following program illustrates the ARTANH function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b ;
   method run();
      a=artanh(.5);
      b=artanh(-.5);
      put 'a=' a;
      put 'b=' b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 0.54930614433405
b= -0.54930614433405
```

ATAN Function

Returns the arctangent in radians.

Category: Trigonometric

Alias: ARTAN

Returned data type: DOUBLE

Syntax

ATAN(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ATAN function returns the 2-quadrant arctangent (inverse tangent) of the argument. The value that is returned is the angle (in radians) whose tangent is x and whose value ranges from $-\pi/2$ to $\pi/2$.

Comparisons

The ATAN function is similar to the ATAN2 function except that ATAN2 calculates the arctangent of the angle from the ratio of two arguments rather than from one argument.

Example

The following program illustrates the ATAN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c;
   method run();
      a=atan(0);
      b=atan(1);
      c=atan(-9);
      put 'a=' a;
      put 'b=' b;
      put 'c=' c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 0
b= 0.78539816339744
c= -1.460139105621
```

See Also

Functions:

- "ATAN2 Function" on page 319

ATAN2 Function

Returns the arctangent of the *x* and *y* coordinates of a right triangle, in radians.

Category:	Trigonometric
Returned data type:	DOUBLE

Syntax

ATAN2 (*expression-1*, *expression-2*)

Required Arguments

expression-1
specifies any valid expression that evaluates to a numeric value. *expression-1* specifies the x coordinate of the end of the hypotenuse of a right triangle.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression-2
specifies any valid expression that evaluates to a numeric value. *expression-2* specifies the y coordinate of the end of the hypotenuse of a right triangle.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ATAN2 function returns the arctangent (inverse tangent) of two numeric variables. The result of this function is similar to the result of calculating the arc tangent of *expression-1* / *expression-2*, except that the signs of both arguments are used to determine the quadrant of the result.

Comparisons

The ATAN2 function is similar to the ATAN function except that ATAN calculates the arctangent of the angle from the value of one argument rather than from two arguments.

Example

The following program illustrates the ATAN2 function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c;
   method run();
      a=atan2(-1, .5);
      b=atan2(6, 8);
      c=atan2(5, -3);
      put 'a=' a;
      put 'b=' b;
      put 'c=' c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= -1.10714871779409
b= 0.64350110879328
c= 2.11121582706548
```

See Also

- "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*

Functions:

- "ATAN Function" on page 318

BAND Function

Returns the bitwise logical AND of two arguments.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BAND(*expression-1* , *expression-2*)

Required Arguments

expression-1
specifies any valid expression that evaluates to a numeric value.

Range between 0 and $(2^{32})-1$ inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression-2
specifies any valid expression that evaluates to a numeric value.

Range	between 0 and $(2^{32})-1$ inclusive
Data type	DOUBLE

Example

The following program illustrates the BAND function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=band(9, 11);
      b=band(15, 5);
      put 'a=' a;
      put 'b=' b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 9
b= 5
```

BETA Function

Returns the value of the beta function.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

BETA(*a*, *b*)

Required Arguments

a
is the first shape parameter.

Range $a > 0$

Data type DOUBLE

b

is the second shape parameter.

Range $b > 0$

Data type DOUBLE

Details

The BETA function is mathematically given by this equation:

$$\beta(a,b) = \int_0^1 x^{a-1}(1-x)^{b-1}dx$$

Note the following:

$$\beta(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$$

In the previous equation, $\Gamma(.)$ is the gamma function.

If the expression cannot be computed, BETA returns a missing value.

Example

The following program illustrates the BETA function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=beta(5, 3);
      b=beta(15, 45);
      put 'a=' a;
      put 'b=' b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 0.0095238095238
b= -4.65396035015752
```

See Also

Functions:

- “LOGBETA Function” on page 832

BETAINV Function

Returns a quantile from the beta distribution.

Category: Quantile

Returned data type: DOUBLE

Syntax

BETAINV(*p*, *a*, *b*)

Required Arguments

p

is a numeric probability.

Range $0 \leq p \leq 1$

Data type DOUBLE

a

is a numeric shape parameter.

Range $a > 0$

Data type DOUBLE

b

is a numeric shape parameter.

Range $b > 0$

Data type DOUBLE

Details

The BETAINV function returns the *p*th quantile from the beta distribution with shape parameters *a* and *b*. The probability that an observation from a beta distribution is less than or equal to the returned quantile is *p*.

Note: BETAINV is the inverse of the PROBBETA function.

Example

The following program illustrates the BETAINV function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y z;
   method run();
      y=betainv(0.001, 2, 4);
      put 'y=' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y= 0.01010178788373
```

See Also

Functions:

- "PROBBETA Function" on page 990

BHAMMING_32 Function

Returns the bitwise Hamming distance between two 32-bit integer values.

Category:	Bitwise Logical Operations
Returned data type:	DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BHAMMING_32(*argument-1*, *argument-2*)

Required Arguments

argument-1
specifies a numeric constant, variable, or expression.

Range An integer value between 0 and $(2^{32})-1$ inclusive

argument-2
specifies a numeric constant, variable, or expression.

Range An integer value between 0 and $(2^{32})-1$ inclusive

Details

The bitwise Hamming distance between two bit strings is the number of positions in the strings where a bit in one string differs from the corresponding bit in the other string.

If either argument contains a missing value, the function returns a missing value and sets _ERROR_ equal to 1. Otherwise, each argument is internally converted to a 32-bit integer. BHAMMING_32 computes the bitwise Hamming distance between these two integers and returns the result as a numeric integer value.

Example

This example shows the functionality of BHAMMING_32.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
  dcl double x y z;

  method run();
    x = 15;
    y = 124;
    z = BHAMMING_32(x,y);
```

```
    put x=binary8.;
    put y=binary8.;
    put z=;
  end;
enddata;
run;
quit;
```

Here is the output from the statements.

```
x=00001111
y=01111100
z=5
```

BHAMMING_HEX Function

Returns the bitwise Hamming distance between two hexadecimal bit strings.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BHAMMING_HEX(*hex-string-1*, *hex-string-2*);

Required Arguments

hex-string-1
specifies a character string containing hexadecimal characters. Leading and trailing blanks are ignored.

Range The maximum length depends on the calling environment.

Note *hex-string-1* and *hex-string-2* must have the same length.

hex-string-2
specifies a character string containing hexadecimal characters. Leading and trailing blanks are ignored.

Range The maximum length depends on the calling environment.

Note *hex-string-1* and *hex-string-2* must have the same length.

Details

The bitwise Hamming distance between two bit strings is the number of positions in the strings where a bit in one string differs from the corresponding bit in the other string.

If either argument is blank, the function returns a missing value and sets _ERROR_ equal to 1. Otherwise, the hexadecimal strings are internally converted to bit strings. BHAMMING_HEX computes the bitwise Hamming distance between these two bit strings and returns the result as a numeric integer value.

Example

This example shows the functionality of BHAMMING_HEX.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
dcl char(3) x y;
dcl double z;

method run();
   x='10F';
   y='17C';
   z = BHAMMING_HEX(x,y);
   put z=;
end;
enddata;
run;
quit;
```

These statements produce this result.

```
z=5
```

BLACKCLPRC Function

Calculates call prices for European options on futures, based on the Black model.

Category:	Financial
Returned data type:	DOUBLE

Syntax

BLACKCLPRC(*E*, *t*, *F*, *r*, *sigma*)

Required Arguments

E

is a nonmissing, positive value that specifies exercise price.

Requirement Specify *E* and *F* in the same units.

Data type DOUBLE

t

is a nonmissing value that specifies time to maturity, in years.

Data type DOUBLE

F

is a nonmissing, positive value that specifies future price.

Requirement Specify *F* and *E* in the same units.

Data type DOUBLE

r

is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type DOUBLE

sigma

is a nonmissing, positive fraction that specifies the volatility (the square root of the variance of *r*).

Data type DOUBLE

Details

The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. The function is based on the following relationship:

$$\text{CALL} = \varepsilon^{-rt}(FN(d_1) - EN(d_2))$$

Arguments

F

specifies future price.

N

specifies the cumulative normal density function.

E
specifies the exercise price of the option.

r
specifies the risk-free interest rate. This is an annual rate that is expressed in terms of continuous compounding.

t
specifies the time to expiration, in years.

$$d_1 = \frac{\left(\ln\left(\frac{F}{E}\right) + \left(\frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$d_2 = d_1 - \sigma\sqrt{t}$$

The following arguments apply to the preceding equation:

σ
specifies the volatility of the underlying asset.

σ^2
specifies the variance of the rate of return.

For the special case of *t*=0, the following equation is true:

$$\text{CALL} = \max((F - E), 0)$$

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. These functions return a scalar value.

Example

The following program illustrates the BLACKCLPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=blackclprc(50, .25, 48, .05, .25);
      b=blackclprc(9, 1/12, 10, .05, .2);
      put 'a=' a;
      put 'b=' b;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 1.55130142723116
b= 1
```

BLACKPTPRC Function

Calculates put prices for European options on futures, based on the Black model.

Category: Financial

Returned data type: DOUBLE

Syntax

BLACKPTPRC(*E*, *t*, *F*, *r*, *sigma*)

Required Arguments

E

is a nonmissing, positive value that specifies exercise price.

Requirement Specify *E* and *F* in the same units.

Data type DOUBLE

t

is a nonmissing value that specifies time to maturity, in years.

Data type DOUBLE

F

is a nonmissing, positive value that specifies future price.

Requirement Specify *F* and *E* in the same units.

Data type DOUBLE

r
is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type DOUBLE

sigma
is a nonmissing, positive fraction that specifies the volatility (the square root of the variance of *r*).

Data type DOUBLE

Details

The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. The function is based on the following relationship:

$$\text{PUT} = \text{CALL} + \varepsilon^{-rt}(E - F)$$

Arguments

E
specifies the exercise price of the option.

r
specifies the risk-free interest rate. This is an annual rate that is expressed in terms of continuous compounding.

t
specifies the time to expiration, in years.

F
specifies future price.

$$d_1 = \frac{\left(\ln\left(\frac{F}{E}\right) + \left(\frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$d_2 = d_1 - \sigma\sqrt{t}$$

The following arguments apply to the preceding equation:

σ
specifies the volatility of the underlying asset.

σ^2
specifies the variance of the rate of return.

For the special case of *t*=0, the following equation is true:

$$\text{PUT} = \max((E - F), 0)$$

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The BLACKPTPRC function calculates put prices for European options on futures, based on the Black model. The BLACKCLPRC function calculates call prices for European options on futures, based on the Black model. These functions return a scalar value.

Example

The following program illustrates the BLACKPTPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=blackptprc(298, .25, 350, .06, .25);
      b=blackptprc(145, .5, 170, .05, .2);
      put 'a=' a;
      put 'b=' b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 1.85980563934967
b= 1.41234979911583
```

BLKSHCLPRC Function

Calculates call prices for European options on stocks, based on the Black-Scholes model.

Category:	Financial
Returned data type:	DOUBLE

Syntax

BLKSHCLPRC(*E*, *t*, *S*, *r*, *sigma*)

Required Arguments

E

is a nonmissing, positive value that specifies the exercise price.

Requirement Specify *E* and *S* in the same units.

Data type DOUBLE

t

is a nonmissing value that specifies the time to maturity, in years.

Data type DOUBLE

S

is a nonmissing, positive value that specifies the share price.

Requirement Specify *S* and *E* in the same units.

Data type DOUBLE

r

is a nonmissing, positive value that specifies the annualized risk-free interest rate, continuously compounded.

Data type DOUBLE

sigma

is a nonmissing, positive fraction that specifies the volatility of the underlying asset.

Data type DOUBLE

Details

The BLKSHCLPRC function calculates the call prices for European options on stocks, based on the Black-Scholes model. The function is based on the following relationship:

$$\text{CALL} = SN(d_1) - EN(d_2)\varepsilon^{-rt}$$

Arguments

S

is a nonmissing, positive value that specifies the share price.

N

specifies the cumulative normal density function.

E
is a nonmissing, positive value that specifies the exercise price of the option.

$$d_1 = \frac{\left(\ln\left(\frac{S}{E}\right) + \left(r + \frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$d_2 = d_1 - \sigma\sqrt{t}$$

The following arguments apply to the preceding equation:

t
specifies the time to expiration, in years.

r
specifies the risk-free interest rate. This is an annual rate that is expressed in terms of continuous compounding.

σ
specifies the volatility (the square root of the variance).

σ^2
specifies the variance of the rate of return.

For the special case of *t*=0, the following equation is true:

$$\text{CALL} = \max((S - E), 0)$$

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The BLKSHCLPRC function calculates the call prices for European options on stocks, based on the Black-Scholes model. The BLKSHPTPRC function calculates the put prices for European options on stocks, based on the Black-Scholes model. These functions return a scalar value.

Example

The following program illustrates the BLKSHCLPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=blkshclprc(50, .25, 48, .05, .25);
      b=blkshclprc(9, 1/12, 10, .05, .2);
      put 'a=' a;
      put 'b=' b;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 1.79894201954462
b= 1
```

Functions:

- "BLKSHCLPRC Function" on page 333

BLSHIFT Function

Returns the bitwise logical left shift of two arguments.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BLSHIFT(*expression-1*, *expression-2*)

Required Arguments

expression-1
specifies any valid expression that evaluates to a numeric value.

Range between 0 and $(2^{32})-1$ inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression-2
specifies any valid expression that evaluates to a numeric value.

Range 0 to 31, inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the BLSHIFT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a;
   method run();
      a=blshift(7, 2);
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
28
```

See Also

Functions:

- "BRSHIFT Function" on page 342

BNOT Function

Returns the bitwise logical NOT of an argument.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BNOT(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Range between 0 and $(2^{32})-1$ inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the BNOT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a;
   method run();
      a=bnot(16);
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
4294967279
```

BOR Function

Returns the bitwise logical OR of two arguments.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BOR(*expression-1, expression-2*)

Required Argument

expression-1, expression-2
specifies any valid expression that evaluates to a numeric value.

Range between 0 and $(2^{32})-1$ inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the BOR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data one (overwrite=yes);
   dcl double x;
   method run();
      x=bor(4, 8);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
12
```

BRSHIFT Function

Returns the bitwise logical right shift of two arguments.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BRSHIFT(*expression-1*, *expression-2*)

Required Arguments

expression-1
specifies any valid expression that evaluates to a numeric value.

Range between 0 and $(2^{32})-1$ inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression-2
specifies any valid expression that evaluates to a numeric value.

Range 0 to 31, inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the BRSHIFT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a;
   method run();
      a=brshift(64, 2);
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
16
```

See Also

Functions:

- "BLSHIFT Function" on page 338

BXOR Function

Returns the bitwise logical EXCLUSIVE OR of two arguments.

Category: Bitwise Logical Operations

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

BXOR(*expression-1, expression-2*)

Required Argument

expression-1, expression-2
specifies any valid expression that evaluates to a numeric value.

Range between 0 and $(2^{32})-1$ inclusive

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the BXOR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data one (overwrite=yes);
   dcl double x;
   method run();
      x=bxor(128, 64);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
192
```

BYTE Function

Returns one character in the ASCII collating sequence.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

BYTE(*n*)

Required Argument

n

specifies a whole number that represents a specific ASCII character.

Range 0–255

Data type DOUBLE

Details

For ASCII collating sequences, the characters that correspond to values between 0 and 127 represent the standard character set. Other ASCII characters that correspond to values between 128 and 255 are available on certain ASCII operating environments, but the information those characters represent varies with the operating environment.

Example

The following program illustrates the BYTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data one (overwrite=yes);
   dcl varchar x;
   method run();
      x=byte(80);
      put x $hex8.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log. The ASCII equivalent of hexadecimal 50 is “P”.

```
50
```

See Also

Functions:

- “RANK Function” on page 1094

CAT Function

Does not remove leading or trailing blanks, and returns a concatenated character string.

Category:	Character
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

CAT(*item-1*[, ...*item-n*])

Required Argument

item
specifies a constant, variable, or expression, either character or numeric. If *item* is numeric, then its value is converted to a character string by using the BEST*w*. format. In this case, leading blanks are removed and SAS does not write a note to the log.

Details

Length of Returned Variable

If the CAT function returns a value to a variable that has not previously been assigned a length, then that variable is given a length of 200 bytes. If the | | or the .. concatenation operator returns a value to a variable that has not previously been assigned a length, then that variable is given a length that is the sum of the lengths of the values that are being concatenated.

Length of Returned Variable: Special Cases

The CAT function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CAT function has the following length:

- up to 200 characters in WHERE clauses and in PROC SQL
- up to 32767 characters in PROC DS2, except in WHERE clauses
- up to 65534 characters when CAT is called from the macro processor

If CAT returns a value in a temporary buffer, the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CAT finishes processing. In this case, SAS does not write a message about the truncation to the log.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS does the following:

- changes the result to a blank line in PROC DS2 and in PROC SQL
- writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
- writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
- sets _ERROR_ to 1

The CAT function removes leading and trailing blanks from numeric arguments after it formats the numeric value with the BEST*w*. format.

Comparisons

The results of the CAT, CATS, CATT, and CATX functions are *usually* equivalent to results that are produced by certain combinations of the concatenation operators || and .. , and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operators. For more information, see “Length of Returned Variable” on page 346.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT.

Example

The following program shows how the CAT function concatenates strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(25) x y z a;
   dcl varchar(70) result;
   method init();
      x='  The 2012 Olym';
      y='pic Arts Festi';
      z='  val included works by D  ';
```

```
        a='ale Chihuly.';
        result=cat(x,y,z,a);
        put result=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=  The 2012 Olympic Arts Festi  val included works by D  ale Chihuly.
```

See Also

Functions:

- “CATQ Function” on page 348
- “CATS Function” on page 353
- “CATT Function” on page 355
- “LEFT Function” on page 816
- “STRIP Function” on page 1179

CATQ Function

Concatenates character or numeric values by using a delimiter to separate items and by adding quotation marks to strings that contain the delimiter.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

CATQ(*modifiers* [, *delimiter*], *item-1* [, ..., *item-n*])

Required Arguments

modifier
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the CATQ function. Blanks are ignored.

You can use the following characters as modifiers:

1 or '
uses single quotation marks when CATQ adds quotation marks to a string.

2 or "
uses double quotation marks when CATQ adds quotation marks to a string.

a or A
adds quotation marks to all of the item arguments.

b or B
adds quotation marks to item arguments that have leading or trailing blanks that are not removed by the S or T modifiers.

c or C
uses a comma as a delimiter.

d or D
indicates that you have specified the delimiter argument.

h or H
uses a horizontal tab as the delimiter.

m or M
inserts a delimiter for every item argument after the first. If you do not use the M modifier, then CATQ does not insert delimiters for item arguments that have a length of zero after processing that is specified by other modifiers. The M modifier can cause delimiters to appear at the beginning or end of the result and can cause multiple consecutive delimiters to appear in the result.

n or N
converts item arguments to name literals when the value does not conform to the usual syntactic conventions for a SAS name. A name literal is a string in quotation marks that is followed by the letter "n" without any intervening blanks. To use name literals in SAS statements, you must specify the SAS option, VALIDVARNAME=ANY.

q or Q
adds quotation marks to item arguments that already contain quotation marks.

s or S
strips leading and trailing blanks from subsequently processed arguments:

- To strip leading and trailing blanks from the delimiter argument, specify the S modifier *before* the D modifier.
- To strip leading and trailing blanks from the item arguments but *not* from the delimiter argument, specify the S modifier *after* the D modifier.

t or T
trims trailing blanks from subsequently processed arguments:

- To trim trailing blanks from the delimiter argument, specify the T modifier before the D modifier.
- To trim trailing blanks from the item arguments but not from the delimiter argument, specify the T modifier after the D modifier.

x or X
converts item arguments to hexadecimal literals when the value contains nonprintable characters.

Tips If *modifier* is a constant, enclose it in quotation marks. You can also express *modifier* as a variable name or an expression.

The A, B, N, Q, S, T, and X modifiers operate internally to the CATQ function. If an item argument is a variable, then the value of that variable is not changed by CATQ unless the result is assigned to that variable.

item
specifies a constant, variable, or expression, either character or numeric. If *item* is numeric, then its value is converted to a character string by using the BEST*w*. format. In this case, leading blanks are removed and SAS does not write a note to the log.

Optional Argument

delimiter
specifies a character constant, variable, or expression that is used as a delimiter between concatenated strings. If you specify this argument, then you must also specify the D modifier.

Details

Length of Returned Variable

The CATQ function returns a value to a variable or if CATQ is called inside an expression, CATQ returns a value to a temporary buffer. The value that is returned has the following length:

- up to 200 characters in WHERE clauses and in PROC SQL
- up to 32767 characters in the DATA step except in WHERE clauses
- up to 65534 characters when CATQ is called from the macro processor

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, then SAS does the following steps:

- changes the result to a blank value in the DATA step and in PROC SQL
- writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
- writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
- sets _ERROR_ to 1 in the DATA step

If CATQ returns a value in a temporary buffer, then the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CATQ finishes processing. In this case, SAS does not write a message about the truncation to the log.

The Basics

If you do not use the C, D, or H modifiers, then CATQ uses a blank as a delimiter.

If you specify neither a quotation mark in *modifier* nor the 1 or 2 modifiers, then CATQ decides independently for each item argument which type of quotation mark to use, if quotation marks are required. The following rules apply:

- CATQ uses single quotation marks for strings that contain an ampersand (&) or percent (%) sign, or that contain more double quotation marks than single quotation marks.
- CATQ uses double quotation marks for all other strings.

The CATQ function initializes the result to a length of zero and then performs the following actions for each item argument:

1. If *item* is not a character string, then CATQ converts *item* to a character string by using the BEST*w*. format and removes leading blanks.
2. If you used the S modifier, then CATQ removes leading blanks from the string.
3. If you used the S or T modifiers, then CATQ removes trailing blanks from the string.
4. CATQ determines whether to add quotation marks based on the following conditions:
   - If you use the X modifier and the string contains control characters, then the string is converted to a hexadecimal literal.
   - If you use the N modifier, then the string is converted to a name literal if either of the following conditions is true:
     - The first character in the string is not an underscore or an English letter.
     - The string contains any character that is not a digit, underscore, or English letter.
   - If you did not use the X or the N modifiers, then CATQ adds quotation marks to the string if any of the following conditions is true:
     - You used the A modifier.
     - You used the B modifier and the string contains leading or trailing blanks that were not removed by the S or T modifiers.
     - You used the Q modifier and the string contains quotation marks.
     - The string contains a substring that equals the delimiter with leading and trailing blanks omitted.
5. For the second and subsequent item arguments, CATQ appends the delimiter to the result if either of the following conditions is true:
   - You used the M modifier.
   - The string has a length greater than zero after it has been processed by the preceding steps.
6. CATQ appends the string to the result.

Comparisons

The CATX function is similar to the CATQ function except that CATX does not add quotation marks.

Example: Concatenating Strings with the CATQ Function

The following program shows how the CATQ function concatenates strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data;
      dcl char(110) result1 result2 result3 result4 result5;
      method init();
         result1=CATQ(' ',
                   'noblanks',
                   'one blank',
                   12345,
                   '  lots of blanks    ');
         put result1=;
         result2=CATQ('CS',
                   'Period (.)                ',
                   'Ampersand (&)             ',
                   'Comma (,)                 ',
                   'Double quotation marks (") ',
                   '   Leading Blanks');
         put result2=;
         result3=CATQ('BCQT',
                   'Period (.)                ',
                   'Ampersand (&)             ',
                   'Comma (,)                 ',
                   'Double quotation marks (") ',
                   '   Leading Blanks');
         put result3=;
         result4=CATQ('ADT',
                   '#=#',
                   'Period (.)                ',
                   'Ampersand (&)             ',
                   'Comma (,)                 ',
                   'Double quotation marks (") ',
                   '   Leading Blanks');
         put result4=;
         result5=CATQ('N',
                   'ABC_123   ',
                   '123    ',
                   'ABC 123');
         put result5=;
      end;
enddata;
```

```
run;
quit;
```

SAS writes the following output to the log:

```
 result1=noblanks "one blank" 12345 " lots of blanks "

 result2=Period (.),Ampersand (&),"Comma (,)",Double quotation marks (),Leading
Blanks

 result3=Period (.),Ampersand (&),"Comma (,)",'Double quotation marks (')'," Leading
Blanks"

 result4="Period (.)"#=#'Ampersand (&)'#=#"Comma (,)"#=#'Double quotation marks
(")'#=#" Leading Blanks"

 result5=ABC_123 "123"n "ABC 123"n
```

Functions:

- “CAT Function” on page 346
- “CATS Function” on page 353
- “CATT Function” on page 355
- “CATX Function” on page 358

CATS Function

Removes leading and trailing blanks, and returns a concatenated character string.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

CATS(*item*[, ...*item*])

Required Argument

item
specifies a constant, variable, or expression, either character or numeric. If *item* is numeric, then its value is converted to a character string by using the BEST*w*. format. In this case, leading blanks are removed and SAS does not write a note to the log.

Details

Length of Returned Variable

If the CATS function returns a value to a variable that has not previously been assigned a length, then that variable is given a length of 200 bytes. If the | | or the .. concatenation operator returns a value to a variable that has not previously been assigned a length, then that variable is given a length that is the sum of the lengths of the values that are being concatenated.

Length of Returned Variable: Special Cases

The CATS function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CATS function has the following length:

- up to 200 characters in WHERE clauses and in PROC SQL
- up to 32767 characters in PROC DS2, except in WHERE clauses
- up to 65534 characters when CATS is called from the macro processor

If CATS returns a value in a temporary buffer, the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CATS finishes processing. In this case, SAS does not write a message about the truncation to the log.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS does the following:

- changes the result to a blank value in PROC DS2 and in PROC SQL
- writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
- writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
- sets _ERROR_ to 1

The CATS function removes leading and trailing blanks from numeric arguments after it formats the numeric value with the BEST*w*. format.

Comparisons

The results of the CAT, CATS, CATT, and CATX functions are *usually* equivalent to results that are produced by certain combinations of the concatenation operators | | and .. , and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operators. For more information, see “Length of Returned Variable” on page 354.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT.

Example

The following program shows how the CATS function concatenates strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(25) x y z a;
   dcl char(70) result;
   method init();
      x='  The   Olym';
      y='pic Arts Festi';
      z='  val includes works by D  ';
      a='ale Chihuly.';
      result=cats(x,y,z,a);
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=The   Olympic Arts Festival includes works by Dale Chihuly.
```

- “CATX Function” on page 358
- “STRIP Function” on page 1179

CATT Function

Removes trailing blanks, and returns a concatenated character string.

Category:	Character
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

CATT(*item*[, ...*item*])

Required Argument

item
specifies a constant, variable, or expression, either character or numeric. If *item* is numeric, then its value is converted to a character string by using the BEST*w*. format. In this case, leading blanks are removed and SAS does not write a note to the log.

Details

Length of Returned Variable

If the CATT function returns a value to a variable that has not previously been assigned a length, then that variable is given a length of 200 bytes. If the | | or the .. concatenation operator returns a value to a variable that has not previously been assigned a length, then that variable is given a length that is the sum of the lengths of the values that are being concatenated.

Length of Returned Variable: Special Cases

The CATT function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CATT function has the following length:

- up to 200 characters in WHERE clauses and in PROC SQL
- up to 32767 characters in PROC DS2, except in WHERE clauses
- up to 65534 characters when CATT is called from the macro processor

If CATT returns a value in a temporary buffer, the length of the buffer depends on the calling environment, and the value in the buffer can be truncated after CATT finishes processing. In this case, SAS does not write a message about the truncation to the log.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS does the following:

- changes the result to a blank value in PROC DS2 and in PROC SQL
- writes a warning message to the log stating that the result was either truncated or set to a blank value, depending on the calling environment
- writes a note to the log that shows the location of the function call and lists the argument that caused the truncation
- sets _ERROR_ to 1

The CATT function removes leading and trailing blanks from numeric arguments after it formats the numeric value with the BEST*w*. format.

Comparisons

The results of the CAT, CATS, CATT, and CATX functions are *usually* equivalent to results that are produced by certain combinations of the concatenation operators | | and .. , and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operators. For more information, see "Length of Returned Variable" on page 356.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT.

Example

The following program shows how the CATT function concatenates strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(25) x y z a;
   dcl char(70) result;
   method init();
      x='  The 2012 Olym';
      y='pic Arts Festi';
      z='  val included works by D  ';
      a='ale Chihuly.';
      result=catt(x,y,z,a);
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=  The 2012 Olympic Arts Festi  val included works by Dale Chihuly.
```

- "CATS Function" on page 353
- "CATX Function" on page 358
- "STRIP Function" on page 1179

CATX Function

Removes leading and trailing blanks, inserts delimiters, and returns a concatenated character string.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

CATX(*delimiter*, *item-1*[, ...*item-n*])

Required Arguments

delimiter
specifies a character string that is used as a delimiter between concatenated items.

item
specifies a constant, variable, or expression, either character or numeric. If *item* is numeric, then its value is converted to a character string by using the BEST*w*. format. In this case, SAS does not write a note to the log. For more information, see "The Basics" on page 358.

Details

The Basics

The CATX function first copies *item-1* to the result, omitting leading and trailing blanks. Then for each subsequent argument *item-i*, i=2, ..., n, if *item-i* contains at least one non-blank character, then CATX appends *delimiter* and *item-i* to the result, omitting leading and trailing blanks from *item-i*. CATX does not insert the delimiter at the beginning or end of the result. Blank items do not produce delimiters at the beginning or end of the result, nor do blank items produce multiple consecutive delimiters.

Length of Returned Variable

The CATX function returns a value to a variable, or returns a value in a temporary buffer. The value that is returned from the CATX function can be up to 32767 characters, except in WHERE clauses.

If the length of the variable or the buffer is not large enough to contain the result of the concatenation, SAS truncates the result.

Comparisons

The results of the CAT, CATS, CATT, and CATX functions are *usually* equivalent to results that are produced by certain combinations of the concatenation operators | | and .. , and the TRIM and LEFT functions. However, the default length for the CAT, CATS, CATT, and CATX functions is different from the length that is obtained when you use the concatenation operator. For more information, see "Length of Returned Variable" on page 358.

Using the CAT, CATS, CATT, and CATX functions is faster than using TRIM and LEFT.

Note: In the case of variables that have missing values, the concatenation produces different results.

Example

The following program shows how the CATX function concatenates strings. The first data program creates the Values table. The second and third data programs use the Values table as input.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* This data program creates the Values table. */
proc ds2;
data values;
   dcl char(4) x1 x2 x3 x4;
   method init();
         /* simple values */
      x1='A'; x2='B'; x3='C'; x4='D';
      output;
      x1='XX'; x2='YY'; x3='ZZ'; x4='WW';
      output;

         /* values with leading, trailing, and embedded white space */
      x1='XX'; x2='Y Y '; x3=' Z Z'; x4=' WW ';
      output;

         /* CHAR set to missing */
      x1='E'; x2= . ; x3='F'; x4='G';
      output;
      x1='H'; x2= . ; x3= . ; x4='J';
      output;

         /* CHAR set to zero-length strings */
      x1='X'; x2='' ; x3='' ; x4='W';
      output;

         /* CHAR set to the null value */
      x1='X'; x2=null; x3='Z' ; x4=null;
```

```
      output;
   end;
run;

   /* This data program creates the Concat1 table. */
data concat1;
   dcl char(1) sp;
   dcl char(4) x1 x2 x3 x4;
   dcl char(20) test1 test2 spacey;
   method run();
     set values;
     SP='^';
     test1 = catx(sp, x1, x2, x3, x4);
     test2 = strip(x1)
             || sp || strip(x2)
             || sp || strip(x3)
             || sp || strip(x4);
     spacey = x1 || sp || x2 || sp || x3 || sp || x4;
   end;
run;

   /* This data program creates the Concat2 table.              */
   /* The example shows what happens when the delimiter contains */
   /* space characters.                                          */
data concat2;
   dcl char(3) sp;
   dcl char(4) x1 x2 x3 x4;
   dcl char(20) test1 test2 spacey;
   method run();
      set values;
      SP = ' ^ ';
      test1 = catx(sp, x1, x2, x3, x4);
      test2 = strip(x1)
              || strip(sp) || strip(x2)
              || strip(sp) || strip(x3)
              || strip(sp) || strip(x4);
      spacey = strip(x1)
              || sp || strip(x2)
              || sp || strip(x3)
              || sp || strip(x4);
   end;
run;
quit;

proc print data=concat1;
   title 'The Concat1 table';
run;

proc print data=concat2;
   title 'The Concat2 table';
run;
```

Output 7.1 *Table Showing Concatenated Characters*

The Concat1 table

Obs	sp	x1	x2	x3	x4	test1	test2	spacey

CDF Function

Computes the left cumulative distribution function from various continuous and discrete probability distributions.

Category: Probability

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064. When an invalid numeric value is given as input for this function, no error message is written to the log, and a missing value is returned as output.

Syntax

CDF(*'distribution'*, *quantile* [, *parameter-1, ..., parameter-k*])

Required Arguments

distribution

is a character constant, variable, or expression that identifies the distribution.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'

Distribution	Argument
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL'|'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD'|'IGAUSS'
Weibull	'WEIBULL'

Note Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

quantile
is a numeric constant, variable, or expression that specifies the value of the random variable.

Data type DOUBLE

Optional Argument

parameter-1, ... , parameter-k
are optional constants, variables, or expressions that specify the values of *shape*, *location*, or *scale* parameters that are appropriate for the specific distribution.

Data type DOUBLE

See Also

CDF BERNOULLI Distribution Function

Returns a value from the Bernoulli cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('BERNOULLI', *x*, *p*)

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

p

is a numeric constant, variable, or expression that specifies a probability of success.

Range $0 \leq p \leq 1$

Data type DOUBLE

Details

The CDF function for the Bernoulli distribution returns the probability that an observation from a Bernoulli distribution, with probability of success equal to *p*, is less than or equal to *x*.

$$CDF('BERN', x, p) = \begin{cases} 0 & x < 0 \\ 1 - p & 0 \le x < 1 \\ 1 & x \ge 1 \end{cases}$$

Note: There are no *location* or *scale* parameters for this distribution.

Example

The following program illustrates the CDF Bernoulli distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('bern', 0, .25);
      put  y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.75
```

CDF BETA Distribution Function

Returns a value from the beta cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('BETA', *x*, *a*, *b* [, *l*, *r*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

b

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $b > 0$

Data type DOUBLE

Optional Arguments

l

is a numeric constant, variable, or expression that specifies the left location parameter.

Default 0

Data type DOUBLE

r

is a numeric constant, variable, or expression that specifies the right location parameter.

Default 1

Range $r > l$

Data type DOUBLE

Details

The CDF function for the beta distribution returns the probability that an observation from a beta distribution, with shape parameters *a* and *b*, is less than or equal to *v*. The following equation describes the CDF function of the beta distribution:

$$CDF('BETA', x, a, b, l, r) = \begin{cases} 0 & x \le l \\ \dfrac{1}{\beta(a,b)} \displaystyle\int_{l}^{x} \dfrac{(v-l)^{a-1}(r-v)^{b-1}}{(r-l)^{a+b-1}} dv & l < x \le r \\ 1 & x > r \end{cases}$$

The following relationship applies to the preceding equation:

$$\beta(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$$

The following relationship applies to the preceding equation:

$$\Gamma(a) = \int_{0}^{\infty} x^{a-1} e^{-x} dx$$

Example

The following program illustrates the CDF Beta distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('beta', 0.2,3,4);
      put  y=;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.09888
```

CDF BINOMIAL Distribution Function

Returns a value from the binomial cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('BINOMIAL', *m*, *p*, *n*)

Required Arguments

m

is a whole number, random variable that counts the number of successes.

Range *m* = 0, 1, ...

Data type DOUBLE

p

is a numeric constant, variable, or expression that specifies a probability of success parameter.

Range $0 \leq p \leq 1$

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies a whole number parameter that counts the number of independent Bernoulli trials.

Range $n = 0, 1, \ldots$

Data type DOUBLE

Details

The CDF function for the binomial distribution returns the probability that an observation from a binomial distribution, with parameters *p* and *n*, is less than or equal to *m*.

$$CDF('BINOM', m, p, n) = \begin{cases} 0 & m < 0 \\ \sum_{j=0}^{m} \binom{n}{j} p^j (1-p)^{n-j} & 0 \leq m \leq n \\ 1 & m > n \end{cases}$$

Note: There are no *location* or *scale* parameters for the binomial distribution.

Example

The following program illustrates the CDF Binomial distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('BINOM', 4, .5, 10);
      put  y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.376953125
```

CDF CAUCHY Distribution Function

Returns a value from the Cauchy cumulative probability distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE
Note:	The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('CAUCHY', *x* [,*θ*] [, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the Cauchy distribution returns the probability that an observation from a Cauchy distribution, with the location parameter θ and the scale parameter λ, is less than or equal to *x*.

$$CDF('CAUCHY', x, \theta, \lambda) = \frac{1}{2} + \frac{1}{\pi} tan^{-1}\left(\frac{x-\theta}{\lambda}\right)$$

Example

The following program illustrates the CDF Cauchy distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('CAUCHY', 2);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.85241638234956
```

CDF Chi-Square Distribution Function

Returns a value from the chi-square cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('CHISQUARE', *x*, *df* [, *nc*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

df

is a numeric constant, variable, or expression that specifies a degrees of freedom parameter.

Range $df > 0$

Data type DOUBLE

Optional Argument

nc

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Range *nc* ≥ 0

Data type DOUBLE

Details

The CDF function for the chi-square distribution returns the probability that an observation from a chi-square distribution, with *df* degrees of freedom and the noncentrality parameter *nc*, is less than or equal to *x*. This function accepts non-integer degrees of freedom. If *nc* is omitted or equal to zero, the value returned is from the central chi-square distribution. In the following equation, let $\nu = df$ and let $\lambda = nc$. The following equation describes the CDF function of the chi-square distribution:

$$CDF('CHISQ', x, \nu, \lambda) = \begin{cases} 0 & x < 0 \\ \sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\left(\frac{\lambda}{2}\right)^j}{j!} P_c(x, \nu + 2j) & x \geq 0 \end{cases}$$

In the equation, $P_c(.,.)$ denotes the probability from the central chi-square distribution:

$$P_c(x, a) = P_g\left(\frac{x}{2}, \frac{a}{2}\right)$$

In the equation, $P_g(y,b)$ is the probability from the gamma distribution given by the equation:

$$P_g(y, b) = \frac{1}{\Gamma(b)} \int_0^y e^{-v} v^{b-1} dv$$

Example

The following program illustrates the CDF Chi-Square distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('CHISQ', 11.264, 11);
      put y=;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.5785813293173
```

CDF Conway-Maxwell-Poisson Distribution Function

Returns a value from the Conway-Maxwell-Poisson cumulative probability distribution.

Category:	Probability
Returned data type:	DOUBLE
Note:	The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('CONMAXPOI', *y*, *λ*,*v*)

Required Arguments

y

is a numeric constant, variable, or expression that specifies a nonnegative whole number that represents counts data.

Data type DOUBLE

λ

is similar to the mean, as in the Poisson distribution.

Data type DOUBLE

v

is a numeric constant, variable, or expression that specifies a dispersion parameter.

Data type DOUBLE

Details

The CDF function returns cumulative probability from 0 to y. For more information, see "Conway-Maxwell-Poisson" distribution in the PDF function on page 941.

Example

The following program illustrates the CDF Conway-Maxwell-Poisson distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('CONMAXPOI', 5, 2.3, .4);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.2445411535065
```

CDF Exponential Distribution Function

Returns a value from the exponential cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('EXPONENTIAL', *x* [,*λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Argument

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the exponential distribution returns the probability that an observation from an exponential distribution, with the scale parameter λ, is less than or equal to *x*.

$$CDF('EXPO', x, \lambda) = \begin{cases} 0 & x < 0 \\ 1 - e^{-\frac{x}{\lambda}} & x \geq 0 \end{cases}$$

Example

The following program illustrates the CDF Exponential distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('expo', 1);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.63212055882855
```

CDF F Distribution Function

Returns a value from the F cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "CDF F Distribution Function" on page 378.

Syntax

CDF('F', *x*, *ndf*, *ddf* [, *nc*])

Required Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

ndf
is a numeric constant, variable, or expression that specifies a numerator degrees of freedom parameter.

Range *ndf* > 0

Data type DOUBLE

ddf
is a numeric constant, variable, or expression that specifies a denominator degrees of freedom parameter.

Range *ddf* > 0

Data type DOUBLE

Optional Argument

nc
is a numeric constant, variable, or expression that specifies a noncentrality parameter.

Range *nc* ≥ 0

Data type DOUBLE

Details

The CDF function for the *F* distribution returns the probability that an observation from an *F* distribution, with *ndf* numerator degrees of freedom, *ddf* denominator degrees of freedom, and the noncentrality parameter *nc*, is less than or equal to *x*. This function accepts noninteger degrees of freedom for *ndf* and *ddf*. If *nc* is omitted or equal to zero, the value returned is from a central *F* distribution. In the following equation, let $\nu_1 = ndf$, let $\nu_2 = ddf$, and let $\lambda = nc$. The following equation describes the CDF function of the *F* distribution:

$$CDF('F', x, \nu_1, \nu_2, \lambda) = \begin{cases} 0 & x < 0 \\ \sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\left(\frac{\lambda}{2}\right)^j}{j!} P_F(x, \nu_1 + 2j, \nu_2) & x \geq 0 \end{cases}$$

In the equation, $P_f(f,u_1,u_2)$ is the probability from the central *F* distribution with

$$P_F(x, u_1, u_2) = P_B\left(\frac{u_1 x}{u_1 x + u_2}, \frac{u_1}{2}, \frac{u_2}{2}\right)$$

and $P_B(x,a,b)$ is the probability from the standard beta distribution.

Note: There are no *location* or *scale* parameters for the *F* distribution.

Example

The following program illustrates the CDF F distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('F', 3.32, 2, 3);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.82639336022431
```

CDF GAMMA Distribution Function

Returns a value from the gamma cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('GAMMA', *x*, *a* [, *λ*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

Optional Argument

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the gamma distribution returns the probability that an observation from a gamma distribution, with the shape parameter *a* and the scale parameter λ, is less than or equal to *x*.

$$CDF('GAMMA', x, a, \lambda) = \begin{cases} 0 & x < 0 \\ \dfrac{1}{\lambda^a \Gamma(a)} \displaystyle\int_0^x v^{a-1} e^{-\frac{v}{\lambda}} dv & x \geq 0 \end{cases}$$

Example

The following program illustrates the CDF Gamma distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=cdf('gamma',1,3);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.08030139707139
```

CDF Generalized Poisson Distribution Function

Returns a value from the generalized Poisson cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('GENPOISSON', *x*, *θ*, *η*)

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Data type DOUBLE

θ

is a numeric constant, variable, or expression that specifies a shape parameter.

Range ≤5 and >0

Data type DOUBLE

η

is a numeric constant, variable, or expression that specifies a shape parameter.

Range ≥0 and <0.95

Data type DOUBLE

Tip When η =0, the distribution is the Poisson distribution with a mean and variance of θ. When η>0, the mean is $\theta \div (1-\eta)$ and the variance is $\theta \div (1-\eta)^3$.

Details

The probability mass function for the generalized Poisson distribution follows:

$$f(x;\theta,\eta) = \theta(\theta+\eta x)^{x-1} e^{-\theta-\eta x}/x!, \quad x = 0,1,2,..., \qquad \theta > 0,\ 0 \le \eta < 1$$

If η =0, then the generalized Poisson distribution becomes the standard Poisson distribution with the shape parameter θ.

Example

The following program illustrates the CDF Generalized Poisson distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double y;
   method run();
      y=cdf('GENPOISSON', 9, 1, .7);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.90616296303524
```

CDF GEOMETRIC Distribution Function

Returns a value from the geometric cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('GEOMETRIC', *m*, *p*)

Required Arguments

m

is a numeric random variable that specifies the number of failures.

Data type DOUBLE

Tip Decimal values are rounded down if they are far away from a whole number.

p

is a numeric constant, variable, or expression that specifies a probability of success.

Range $0 \leq p \leq 1$

Data type DOUBLE

Details

The CDF function for the geometric distribution returns the probability that an observation from a geometric distribution, with the parameter *p*, is less than or equal to *m*.

$$CDF('GEOM', m, p) = \begin{cases} 0 & m < 0 \\ 1 - (1-p)^{(m+1)} & m \geq 0 \end{cases}$$

Note: There are no *location* or *scale* parameters for this distribution.

Example

The following program illustrates the CDF Geometric distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=cdf('GEOMETRIC',5, .35);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.924581109375
```

CDF HYPERGEOMETRIC Distribution Function

Returns a value from the hypergeometric cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('HYPER', *x*, *N*, *R*, *n* [, *o*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Data type DOUBLE

N

is a numeric constant, variable, or expression that specifies a population size parameter. This argument must be a whole number.

Range $N = 1, 2, \ldots$

Data type DOUBLE

R

is a numeric constant, variable, or expression that specifies a number of items in the category of interest. This argument must be a whole number.

Range $R = 0, 1, \ldots, N$

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies a sample size parameter. This argument must be a whole number.

Range $n = 1, 2, \ldots, N$

Data type DOUBLE

Optional Argument

o

is a numeric constant, variable, or expression that specifies an optional numeric odds ratio parameter.

Range $o > 0$

Data type DOUBLE

Details

The CDF function for the hypergeometric distribution returns the probability that an observation from an extended hypergeometric distribution, with population size *N*, number of items *R*, sample size *n*, and odds ratio *o*, is less than or equal to *x*. If *o* is omitted or equal to 1, the value returned is from the usual hypergeometric distribution.

$$CDF\ ('HYPER', x, N, R, n, o) = \begin{cases} 0 & x < max(0, R+n-N) \\ \dfrac{\sum_{i=0}^{x} \binom{R}{i}\binom{N-R}{n-i} o^i}{\sum_{j=max(0,R+n-N)}^{min(R,n)} \binom{R}{j}\binom{N-R}{n-j} o^j} & max(0, R+n-N) \le x \le min(R, n) \\ 1 & x > min(R, n) \end{cases}$$

Example

The following program illustrates the CDF Hypergeometric distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('HYPER',2,200,50,10);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.52367340812173
```

CDF LAPLACE Distribution Function

Returns a value from the Laplace cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('LAPLACE', *x* [,*θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the Laplace distribution returns the probability that an observation from the Laplace distribution, with the location parameter θ and the scale parameter λ, is less than or equal to *x*.

$$CDF('LAPLACE', x, \theta, \lambda) = \begin{cases} \frac{1}{2}e^{\frac{(x-\theta)}{\lambda}} & x < \theta \\ 1 - \frac{1}{2}e^{\left(-\frac{(x-\theta)}{\lambda}\right)} & x \geq \theta \end{cases}$$

Example

The following program illustrates the CDF Laplace distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('LAPLACE',1);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.81606027941427
```

CDF LOGISTIC Distribution Function

Returns a value from the logistic cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('LOGISTIC', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the Logistic distribution returns the probability that an observation from a Logistic distribution, with the location parameter θ and the scale parameter λ, is less than or equal to *x*.

$$CDF('LOGISTIC', x, \theta, \lambda) = \frac{1}{1 + e^{\left(-\frac{x-\theta}{\lambda}\right)}}$$

Example

The following program illustrates the CDF Logistic distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('LOGISTIC',1);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.73105857863
```

CDF LOGNORMAL Distribution Function

Returns a value from the lognormal cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('LOGNORMAL', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a log scale parameter. e(θ) is a scale parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a shape parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the lognormal distribution returns the probability that an observation from a lognormal distribution, with the log scale parameter θ and the shape parameter λ, is less than or equal to *x*.

$$CDF('LOGN', x, \theta, \lambda) = \begin{cases} 0 & x \le 0 \\ \frac{1}{\lambda\sqrt{2\pi}} \int_{-\infty}^{log(x)} e\left(-\frac{(v-\theta)^2}{2\lambda^2}\right) dv & x > 0 \end{cases}$$

Example

The following program illustrates the CDF Lognormal distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('LOGNORMAL',1);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.5
```

CDF NEGBINOMIAL Distribution Function

Returns a value from the negative binomial cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('NEGBINOMIAL', *m*, *p*, *n*)

Required Arguments

m

is a numeric constant, variable, or expression that specifies a random variable that counts the number of failures. This argument must be a positive whole number.

Range $m = 0, 1, \ldots$

Data type DOUBLE

p

is a numeric constant, variable, or expression that specifies a probability of success.

Range $0 \leq p \leq 1$

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies a value that counts the number of successes.

Range $n > 0$

Data type DOUBLE

Details

The CDF function for the negative binomial distribution returns the probability that an observation from a negative binomial distribution, with the probability of success *p* and the number of successes *n*, is less than or equal to *m*.

$$CDF('NEGB', m, p, n) = \begin{cases} 0 & m < 0 \\ p^n \sum_{j=0}^{m} \binom{n+j-1}{n-1} (1-p)^j & m \geq 0 \end{cases}$$

Note: There are no *location* or *scale* parameters for the negative binomial distribution.

Example

The following program illustrates the CDF Negative Binomial distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('NEGB',1,.5,2);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.5
```

CDF NORMAL Distribution Function

Returns a value from the normal cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('NORMAL', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the Normal distribution returns the probability that an observation from the Normal distribution, with the location parameter θ and the scale parameter λ, is less than or equal to *x*.

$$CDF('NORMAL', x, \theta, \lambda) = \frac{1}{\lambda\sqrt{2\pi}} \int_{-\infty}^{x} e\left(-\frac{(v-\theta)^2}{2\lambda^2}\right) dv$$

Example

The following program illustrates the CDF Normal distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('NORMAL',1.96);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.97500210485177
```

CDF NORMALMIX Distribution Function

Returns a value from the normal mixture cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('NORMALMIX', *x*, *n*, *p*, *m*, *s*)

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies the number of mixtures.

Range *n* = 1, 2, ...

Data type DOUBLE

p

is a numeric constant, variable, or expression that specifies the *n* proportions, $p_1, p_2, \ldots, p_n$, where $\sum_{i=1}^{i=n} p_i = 1$.

Range *p* = 0, 1, ...

Data type DOUBLE

m

is a numeric constant, variable, or expression that specifies the *n* means $m_1, m_2, \ldots, m_n$.

Data type DOUBLE

s

is a numeric constant, variable, or expression that specifies the *n* standard deviations $s_1, s_2, \ldots, s_n$.

Range $s > 0$

Data type DOUBLE

Details

The CDF function for the Normal Mixture distribution returns the probability that an observation from a mixture of normal distribution is less than or equal to *x*.

$$CDF('NORMALMIX', x, n, p, m, s) = \sum_{i=1}^{i=n} p_i \, CDF('NORMAL', x, m_i, s_i)$$

Weights for the Normal Mixture distribution must be nonnegative. If the sum of the weights does not equal 1, then the weights are treated as relative weights and adjusted so that the sum equals 1.

Note: There are no *location* or *scale* parameters for the Normal Mixture distribution.

Example

The following program illustrates the CDF Normal Mixture distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('Normalmix',2.3,3,.33,.33,.34,.5,1.5,2.5,.79,1.6,4.3);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.71813087231314
```

CDF PARETO Distribution Function

Returns a value from the Pareto cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('PARETO', *x*, *a* [, *k*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

Optional Argument

k

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range $k > 0$

Data type DOUBLE

Details

The CDF function for the Pareto distribution returns the probability that an observation from a Pareto distribution, with the shape parameter *a* and the scale parameter *k*, is less than or equal to *x*.

$$CDF('PARETO', x, a, k) = \begin{cases} 0 & x < k \\ 1 - \left(\frac{k}{x}\right)^a & x \geq k \end{cases}$$

Example

The following program illustrates the CDF Pareto distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('PARETO',1,1);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0
```

CDF POISSON Distribution Function

Returns a value from the Poisson cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('POISSON', *n*, *m*)

Required Arguments

n

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Range *n* = 0, 1, ...

Data type DOUBLE

m

is a numeric constant, variable, or expression that specifies a mean parameter.

Range *m* > 0

Data type DOUBLE

Details

The CDF function for the Poisson distribution returns the probability that an observation from a Poisson distribution, with mean *m*, is less than or equal to *n*.

$$CDF('POISSON', n, m) = \begin{cases} 0 & n < 0 \\ \sum_{i=0}^{n} e^{-m}\frac{m^i}{i!} & n \geq 0 \end{cases}$$

Note: There are no *location* or *scale* parameters for the Poisson distribution.

Example

The following program illustrates the CDF Poisson distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('POISSON',2,1);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.9196986029286
```

CDF T Distribution Function

Returns a value from the T cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF('T', *t*, *df* [, *nc*])

Required Arguments

t

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

df

is a numeric constant, variable, or expression that specifies the degrees of freedom.

Range $df > 0$

Data type DOUBLE

Optional Argument

nc

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Data type DOUBLE

Details

The CDF function for the *T* distribution returns the probability that an observation from a *T* distribution, with degrees of freedom *df* and the noncentrality parameter *nc*, is less than or equal to *x*. This function accepts noninteger degrees of freedom.

If *nc* is omitted or equal to zero, the value returned is from the central *T* distribution. In the following equation, let $\nu = df$ and let $\delta = nc$.

$$CDF('T', t, \nu, \delta) = \frac{1}{2^{(\nu/2-1)}\Gamma\left(\frac{\nu}{2}\right)} \int_0^{\infty} x^{\nu-1} e^{-\frac{1}{2}x^2} \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\frac{tx}{\sqrt{\nu}}} e^{-\frac{1}{2}(u-\delta)^2} du dx$$

Note: There are no *location* or *scale* parameters for the *T* distribution.

Example

The following program illustrates the CDF T distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
     y=cdf('T',.9,5);
     put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.79531439982768
```

CDF TWEEDIE Distribution Function

Returns a value from the Tweedie cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see "QUANTILE Function" on page 1064.

Syntax

CDF ('TWEEDIE', *y*, *p* [, *μ*, *ϕ*])

Required Arguments

y

is a numeric constant, variable, or expression that specifies a random variable.

Range $y \geq 0$

Data type DOUBLE

Notes This argument is required.

When $p>1$, y is numeric. When $p=1$, y is a whole number.

p

is a numeric constant, variable, or expression that specifies the power parameter.

Range $p \geq 1$

Data type DOUBLE

Note This argument is required.

Optional Arguments

μ

is a numeric constant, variable, or expression that specifies the mean parameter.

Default 1

Range $\mu>0$

Data type DOUBLE

ϕ

is a numeric constant, variable, or expression that specifies the dispersion parameter.

Default 1

Range $\phi>0$

Data type DOUBLE

Details

The CDF function for the Tweedie distribution returns an exponential dispersion model with variance and mean related by the equation $variance = \phi \times \mu^p$.

$$\int_0^y \frac{1}{y} \sum_{j=1}^{\infty} \left(\frac{y^{-j\alpha}(p-1)^{ja}}{\phi^{j(1-\alpha)}(2-p)^j j!\,\Gamma(-j\alpha)} \right) e\left(\frac{1}{\phi}\left(y\frac{\mu^{1-p}-1}{1-p} - \frac{\mu^{2-p}-1}{2-p} \right) \right) dy$$

The following relationship applies to the preceding equation:

$$\alpha = \frac{2-p}{1-p}$$

Note: The accuracy of computed Tweedie probabilities is highly dependent on the location in parameter space. Ten digits of accuracy are usually available except when *p* is near 2 or phi is near 0. In that case, the accuracy might be as low as six digits.

Example

The following program illustrates the CDF Tweedie distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('TWEEDIE', .8, 5);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.59176291643197
```

CDF UNIFORM Distribution Function

Returns a value from the uniform cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('UNIFORM', *x* [, *l*, *r*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

l

is a numeric constant, variable, or expression that specifies the left location parameter.

Default 0

Data type DOUBLE

r

is a numeric constant, variable, or expression that specifies the right location parameter.

Default 1

Range $r > l$

Data type DOUBLE

Details

The CDF function for the uniform distribution returns the probability that an observation from a uniform distribution, with the left location parameter *l* and the right location parameter *r*, is less than or equal to *x*.

$$CDF('UNIFORM', x, l, r) = \begin{cases} 0 & x < l \\ \frac{x-l}{r-l} & l \le x < r \\ 1 & x \ge r \end{cases}$$

Note: The default values for *l* and *r* are 0 and 1, respectively.

Example

The following program illustrates the CDF Uniform distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
     y=cdf('UNIFORM',0.25);
     put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.25
```

CDF WALD (Inverse Gaussian) Distribution Function

Returns a value from the Wald (also known as the inverse Gaussian) cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('WALD', *x*, *λ* [, *μ*])

CDF('IGAUSS', *x*, *λ* [, *μ*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $\lambda > 0$

Data type DOUBLE

Optional Argument

μ

is a numeric constant, variable, or expression that specifies the mean parameter.

Default 1

Range μ > 0

Data type DOUBLE

Details

The CDF function for the Wald distribution returns the probability that an observation from a Wald distribution, with the shape parameter λ, is less than or equal to x.

$$Fx(x) = \Phi\left\{\sqrt{\frac{\lambda}{x}}\left(\frac{x}{\mu} - 1\right)\right\} + e^{2\lambda/\mu}\Phi\left\{-\sqrt{\frac{\lambda}{x}}\left(\frac{x}{\mu} + 1\right)\right\}$$

In the equation, $\Phi(.)$ is the standard normal cumulative distribution function. When x≤0, CDF is 0.

Example

The following program illustrates the CDF Wald distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
     y=cdf('WALD',1,2);
     put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.62769783815525
```

CDF WEIBULL Distribution Function

Returns a value from the Weibull cumulative probability distribution.

Category: Probability

Returned data type: DOUBLE

Note: The QUANTILE function returns the quantile from a distribution that you specify. The QUANTILE function is the inverse of the CDF function. For more information, see “QUANTILE Function” on page 1064.

Syntax

CDF('WEIBULL', *x*, *a* [, *λ*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

Optional Argument

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The CDF function for the Weibull distribution returns the probability that an observation from a Weibull distribution, with the shape parameter *a* and the scale parameter λ, is less than or equal to *x*.

$$CDF('WEIBULL', x, a, \lambda) = \begin{cases} 0 & x < 0 \\ 1 - e^{-\left(\frac{x}{\lambda}\right)^a} & x \geq 0 \end{cases}$$

Example

The following program illustrates the CDF Weibull distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method init();
      y=cdf('WEIBULL',1,2);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=0.63212055882855
```

CEIL Function

Returns the smallest integer greater than or equal to a numeric value expression.

Category: Truncation

Returned data type: DECIMAL, DOUBLE, NUMERIC

Syntax

CEIL(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DECIMAL, DOUBLE, NUMERIC

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If the result is a number that does not fit into the range of the argument's data type, the CEIL function fails.

If the argument is DECIMAL, the result is DECIMAL. Otherwise, the argument is converted to DOUBLE (if not so already), and the result is DOUBLE.

Comparisons

Unlike the CEILZ function, the CEIL function fuzzes the result. If the argument is within 1E-12 of an integer, the CEIL function fuzzes the result to be equal to that

integer. The CEILZ function does not fuzz the result. Therefore, with the CEILZ function, you might get unexpected results.

Example

The following program illustrates the CEIL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double var1 a b c d e f g h;
   method run();
      var1=2.1;
      a=ceil(var1);
      b=ceil(-2.4);
      c=ceil(1+1.e-11);
      d=ceil(-1+1.e-11);
      e=ceil(1+1.e-13);
      f=ceil(223.456);
      g=ceil(763);
      h=ceil(-223.456);
      put  'a= ' a;
      put  'b= ' b;
      put  'c= ' c;
      put  'd= ' d;
      put  'e= ' e;
      put  'f= ' f;
      put  'g= ' g;
      put  'h= ' h;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a=  3
b=  -2
c=  2
d=  0
e=  1
f=  224
g=  763
h=  -223
```

See Also

Functions:

- “CEILZ Function” on page 416

- "FLOOR Function" on page 659
- "FLOORZ Function" on page 662

CEILZ Function

Returns the smallest integer that is greater than or equal to the argument, using zero fuzzing.

Category: Truncation

Returned data type: DOUBLE

Syntax

CEILZ(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Comparisons

Unlike the CEIL function, the CEILZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the CEIL function fuzzes the result to be equal to that integer. The CEILZ function does not fuzz the result. Therefore, with the CEILZ function, you might get unexpected results.

Example

The following program illustrates the CEILZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c d e f g h;
   method run();
```

```
        a=ceilz(2.1);
        b=ceilz(-2.4);
        c=ceilz(1+1.e-11);
        d=ceilz(-1+1.e-11);
        e=ceilz(1+1.e-13);
        f=ceilz(223.456);
        g=ceilz(763);
        h=ceilz(-223.456);
        put  'a= ' a;
        put  'b= ' b;
        put  'c= ' c;
        put  'd= ' d;
        put  'e= ' e;
        put  'f= ' f;
        put  'g= ' g;
        put  'h= ' h;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a=  3
b=  -2
c=  2
d=  0
e=  2
f=  224
g=  763
h=  -223
```

CHOOSEC Function

Returns a character value that represents the results of choosing from a list of arguments.

Category:	Character
Returned data type:	VARCHAR, NVARCHAR

Syntax

CHOOSEC(*index-expression*, *selection-1*[, ...*selection-n*])

Required Arguments

index-expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

selection
specifies a character constant, variable, or expression. The value of this argument is returned by the CHOOSEC function.

Data type CHAR, VARCHAR, NCHAR, NVARCHAR

Details

The CHOOSEC function uses the value of *index-expression* to select from the arguments that follow. For example, if *index-expression* is 3, CHOOSEC returns the value of *selection-3*. If the first argument is negative, the function counts backward from the list of arguments, and returns that value.

Comparisons

The CHOOSEC function is similar to the CHOOSEN function except that CHOOSEC returns a character value while CHOOSEN returns a numeric value.

Example

The following program shows how CHOOSEC chooses from a series of values:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char fruit color planet sport;
   method init();
      Fruit=choosec(1, 'apple', 'orange', 'pear', 'fig');
      Color=choosec(3, 'red', 'blue', 'green', 'yellow');
      Planet=choosec(2, 'Mars', 'Mercury', 'Uranus');
      Sport=choosec(-3, 'soccer', 'baseball', 'gymnastics', 'skiing');
```

```
      put Fruit= Color= Planet= Sport=;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
fruit=apple    color=green    planet=Mercury  sport=baseball
```

See Also

Functions:

- "CHOOSEN Function" on page 419

CHOOSEN Function

Returns a numeric value that represents the results of choosing from a list of arguments.

Category: Numeric

Returned data type: DOUBLE

Syntax

CHOOSEN(*index-expression*, *selection-1*[, ...*selection-n*])

Required Arguments

index-expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

selection
specifies a numeric constant, variable, or expression. The value of this argument is returned by the CHOOSEN function.

Data type DOUBLE

Details

The CHOOSEN function uses the value of *index-expression* to select from the arguments that follow. For example, if *index-expression* is 3, CHOOSEN returns the value of *selection-3*. If the first argument is negative, the function counts backward from the list of arguments, and returns that value.

Comparisons

The CHOOSEN function is similar to the CHOOSEC function except that CHOOSEC returns a character value while CHOOSEN returns a numeric value.

Example

The following program shows how CHOOSEN chooses from a series of values:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test;
   dcl double itemnumber rank score value;
   method run();
      ItemNumber=choosen(5,100,50,3784,498,679);
      Rank=choosen(-2,1,2,3,4,5);
      Score=choosen(3,193,627,33,290,5);
      Value=choosen(-5,-37,82985,-991,3,1014,-325,3,54,-618);
      put 'ItemNumber= ' ItemNumber;
      put 'Rank= ' Rank;
      put 'Score= ' Score;
      put 'Value= ' Value;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
ItemNumber=  679
Rank=  4
Score=  33
Value=  1014
```

CMISS Function

Counts the number of missing arguments.

Category: Descriptive Statistics

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

CMISS(*argument* [, ...*argument*,])

Required Argument

argument
specifies a constant, variable, or expression. *argument* can be either a character value or a numeric value.

Details

A character expression is counted as missing if it evaluates to a string that contains all blanks or has a length of zero, except when you use the CMISS function in macro processing. A numeric expression is counted as missing if it evaluates to a numeric missing value: ., ._, .A, ... , .Z.

When you use the CMISS function in macro processing, use a period (.) to represent both a character and a numeric missing value. If you use a blank or null value for a character argument, SAS returns an error. Here are three examples that result in an error:

```
%let macvar=%sysfunc(cmiss(A,%str( )));
%let macvar=%sysfunc(cmiss(A, ));
%let macvar=%sysfunc(cmiss(A,));
```

Here is the example to use to avoid the error condition:

```
%let macvar=%sysfunc(cmiss(A,.));
```

Example

The following program illustrates the CMISS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char a b;
   method run();
      a=cmiss(1,0, ' ' , 2,5,' ');
```

```
        b=cmiss(1, ' ');
        put  'a=' a;
        put 'b=' b;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a= 2
b= 1
```

Functions:

- “MISSING Function” on page 865
- “NMISS Function” on page 882

CMP Function

Compares two character strings including trailing blanks.

Category: Character

Returned data type: BIGINT

Syntax

CMP (*string-1*, *string-2*)

Required Arguments

string-1
specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

string-2
specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

In the CMP function, if *string-1* and *string-2* do not differ, CMP returns a value of zero. If the arguments differ, the sign of the result is negative if *string-1* precedes string-2 in a sort sequence, and positive if *string-1* follows *string-2* in a sort sequence.

The CMP function does not remove trailing blanks.

Comparisons

The CMP function compares two strings but does not remove trailing blanks. The CMPT function compares two strings and does remove trailing blanks.

Example

The following program uses the CMP function to compare two different strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double nopad pad greaterthan lessthan;
   method run();
      nopad=cmp('abc', 'def');
      pad=cmp('abc', 'abc ');
      greaterthan=cmp('abc', 'abcdef');
      lessthan=cmp('abcdef', 'abc');
      put nopad= pad= greaterthan= lessthan=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
nopad=-1 pad=-4 greaterthan=-4 lessthan=4
```

See Also

Functions:

- “CMPT Function” on page 424

CMPT Function

Compares two character strings excluding trailing blanks.

Category: Character

Returned data type: BIGINT

Syntax

CMPT (*string-1*, *string-2*)

Required Arguments

string-1
specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

string-2
specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

In the CMPT function, if *string-1* and *string-2* do not differ, CMPT returns a value of zero. If the arguments differ, the sign of the result is negative if *string-1* precedes string-2 in a sort sequence, and positive if *string-1* follows *string-2* in a sort sequence.

The CMPT function removes trailing blanks.

Comparisons

The CMPT function compares two strings and removes trailing blanks. The CMP function compares two strings and does not remove trailing blanks.

Example

The following program uses the CMPT function to compare two different strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
dcl double nopad pad greaterthan lessthan;
   method run();
      nopad=cmpt('abc', 'def');
      pad=cmpt('abc', 'abc ');
      greaterthan=cmpt('abc', 'abcdef');
      lessthan=cmpt('abcdef', 'abc');
      put nopad= pad= greaterthan= lessthan=;
   end;
enddata;
run;
quit;
```

```
nopad=0 pad=0 greaterthan=-4 lessthan=4
```

Functions:

- "CMP Function" on page 422

CNONCT Function

Returns the noncentrality parameter from a chi-square distribution.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

CNONCT(*x*, *df*, *probability*)

Required Arguments

x
is a numeric random variable.

Range $x \geq 0$

Data type DOUBLE

df
is a numeric degrees of freedom parameter.

Range $df > 0$

Data type DOUBLE

probability
is a probability.

Range $0 < probability < 1$

Data type DOUBLE

Details

The CNONCT function returns the nonnegative noncentrality parameter from a noncentral chi-square distribution whose parameters are *x*, *df*, and *nc*. If *probability* is greater than the probability from the central chi-square distribution with the parameters *x* and *df*, a root to this problem does not exist. In this case a missing value is returned. A Newton-type algorithm is used to find a nonnegative root *nc* of the equation

$$P_c(x|\mathrm{df}, nc) - prob = 0$$

The following relationship applies to the preceding equation:

$$P_c(x|\mathrm{df}, \mathrm{nc}) = \varepsilon^{\frac{-nc}{2}} \sum_{j=0}^{\infty} \frac{\left(\frac{nc}{2}\right)^j}{j!} P_g\left(\frac{x}{2}\middle|\frac{df}{2} + j\right)$$

The following relationship applies to the preceding equation:

$$P_g(x|a)$$

is the probability from the gamma distribution given by

$$P_g(x|a) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} \varepsilon^{-t} dt$$

If the algorithm fails to converge to a fixed point, a missing value is returned.

Example

This example illustrates the CNONCT function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data work /overwrite=yes;
   dcl double x df nc prob ncc;
   method init();
      x=2;
      df=4;
      do nc=1 to 3 by .5;
         prob=probchi(x, df, nc);
         ncc=cnonct(x, df, prob);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=work;
run;
```

Output 7.3 *Computations of the Noncentrality Parameters from the Chi-squared Distribution*

Obs	x	df	nc	prob	ncc
1	2	4	1.0	0.18611	1.0
2	2	4	1.5	0.15592	1.5
3	2	4	2.0	0.13048	2.0
4	2	4	2.5	0.10907	2.5
5	2	4	3.0	0.09109	3.0

COALESCE Function

Returns the first non-null or nonmissing value from a list of numeric arguments.

Category:	Mathematical
Returned data type:	DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

COALESCE(*expression*[, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

COALESCE accepts one or more numeric expressions. The COALESCE function checks the value of each expression in the order in which they are listed and returns the first non-null or nonmissing value. If only one value is listed, then the COALESCE function returns the value of that argument. If all the values of all expressions are null or missing, then the COALESCE function returns a null or a missing value depending on whether you are in ANSI mode or SAS mode. For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

Comparisons

The COALESCE function searches numeric expressions, whereas the COALESCEC function searches character expressions.

Example

The following program illustrates the COALESCE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data one(overwrite=yes);
   dcl double w x y z;
```

```
      method run();
         w = coalesce(., .A, 33, 22, 44, .);
         x = coalesce(42, .);
         y = coalesce(.A, .B, .C);
         z = coalesce(., 7, ., ., 42);
         put w=;
         put x=;
         put y=;
         put z=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log.

```
w=33
x=42
y=.
z=7
```

Functions:

- "COALESCEC Function" on page 429

COALESCEC Function

Returns the first non-null or nonmissing value from a list of character arguments.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

COALESCEC(*expression*[, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

COALESCEC accepts one or more character expressions. The COALESCEC function checks the value of each expression in the order in which they are listed and returns the first non-null or nonmissing value. If only one value is listed, then the COALESCEC function returns the value of that expression. If all the values of all expressions are null or missing, then the COALESCEC function returns a null or missing value depending on whether you are in ANSI mode or SAS mode. For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

Comparisons

The COALESCEC function searches character expressions, whereas the COALESCE function searches numeric expressions.

Example

The following program illustrates the COALESCEC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char a b;
   method run();
      a=coalescec('', 'Hello');
      put a;
      b=coalescec('', 'Goodbye', 'Hello');
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
Hello
Goodbye
```

See Also

Functions:

- "COALESCE Function" on page 427

COMB Function

Computes the number of combinations of *n* elements taken *r* at a time.

Category: Combinatorial

Returned data type: DOUBLE

Syntax

COMB(*n*, *r*)

Required Arguments

n

is a nonnegative whole number that represents the total number of elements from which the sample is chosen.

Data type DOUBLE

r

is a nonnegative whole number that represents the number of chosen elements.

Restriction $r \le n$

Data type DOUBLE

Details

The mathematical representation of the COMB function is given by the following equation:

$$COMB\,(n, r) = \binom{n}{r} = \frac{n!}{r!\,(n-r)!}$$

In the preceding equation, $n \ge 0$, $r \ge 0$, and $n \ge r$.

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the COMB function.

Example

The following program illustrates the COMB function:

```
proc ds2;
data _null_;
   vararray char x[5];
   dcl double k n ncomb;
   method init();
      x:=('ant' 'bee' 'cat' 'dog' 'ewe');
   end;
   method run();
      n=dim(x);
      k=3;
      ncomb=comb(n, k);
      put ncomb=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
ncomb=10
```

See Also

Functions:

- “FACT Function” on page 537
- “PERM Function” on page 981

COMPARE Function

Returns the position of the leftmost character by which two strings differ, or returns 0 if there is no difference.

Category:	Character
Returned data type:	DOUBLE

Syntax

COMPARE(*string-1*, *string-2*[, *modifiers*])

Required Arguments

string-1
specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

string-2
specifies a character constant, variable, or expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Optional Argument

modifiers
specifies a character string that can modify the action of the COMPARE function.

You can use one or more of the following characters as a valid modifier:

i
ignores the case in *string-1* and *string-2*.

l
removes leading blanks in *string-1* and *string-2* before comparing the values.

n
removes quotation marks from any argument that is a name literal and ignores the case of *string-1* and *string-2*. A name literal is a name token that is expressed as a string within quotation marks, followed by the uppercase or lowercase letter *n*. Name literals enable you to use special characters (including blanks) that are not otherwise allowed in table or variable names. For COMPARE to recognize a string as a name literal, the first character must be a quotation mark.

:
(colon) truncates the longer of *string-1* or *string-2* to the length of the shorter string, or to one, whichever is greater. If you do not specify this modifier, the shorter string is padded with blanks to the same length as the longer string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip COMPARE ignores blanks that are used as modifiers.

Details

The Basics

The order in which the modifiers appear in the COMPARE function is relevant.

- "LN" first removes leading blanks from each string, and then removes quotation marks from name literals.
- "NL" first removes quotation marks from name literals, and then removes leading blanks from each string.

In the COMPARE function, if *string-1* and *string-2* do not differ, COMPARE returns a value of zero. If the arguments differ, then the following apply:

- The sign of the result is negative if *string-1* precedes *string-2* in a sort sequence, and positive if *string-1* follows *string-2* in a sort sequence.
- The magnitude of the result is equal to the position of the leftmost character at which the strings differ.

DBCS Compatibility

The DBCS equivalent function is KCOMPARE. There are minor differences between the COMPARE and KCOMPARE functions. Both functions accept varying numbers of arguments, but usage of the third argument is not compatible. The following example shows the differences in the syntax:

COMPARE(*string-1*, *string-2*[, *modifiers*])

KCOMPARE(*string-1*[, *position*[, *count*]], *string-2*)

For more information, see the "KCOMPARE Function" in *SAS National Language Support (NLS): Reference Guide*.

Examples

Example 1: Understanding the Order of Comparisons When Comparing Two Strings

The following program compares two strings by using the COMPARE function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test /overwrite=yes;
   dcl char string1 string2 modifiers having informat $char8. format
$char8.;
   method init();
      string1='12345678'; string2='12345678'; output;
      string1='123'; string2='abc'; output;
      string1='abc'; string2='abx'; output;
      string1='xyz'; string2='abcdef'; output;
```

```
      string1='aBc'; string2='abc'; output;
      string1='aBc'; string2='AbC'; modifiers='i'; output;
      string1='   abc  '; string2='abc'; modifiers=' '; output;
      string1='   abc  '; string2='abc'; modifiers='l'; output;
      string1=' abc    '; string2='   abx  '; modifiers=' ';output;
      string1=' abc    '; string2='   abx  '; modifiers='l';  output;
   end;
enddata;
run;

data test_out /overwrite=yes;
   method run();
      set test;
      result=compare(string1, string2, modifiers);
      put 'String 1= ' string1 'String 2= ' string2 'Modifier= '
modifiers
         'Result= ' result;
   end;
run;
quit;

proc print data=test_out noobs;run;quit;
```

Output 7.4 *Results of Comparing Two Strings By Using the COMPARE Function*

string1	string2	modifiers	result
12345678	12345678		0
123	abc		-1
abc	abx		-3
xyz	abcdef		1
aBc	abc		-2
aBc	AbC	i	0
abc	abc		-1
abc	abc	l	0
abc	abx		2
abc	abx	l	-3

Example 2: Truncating Strings Using the COMPARE Function

The following program uses the : (colon) modifier to truncate strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test2 /overwrite=yes;
   dcl double pad1 pad2 truncate1 truncate2 blank;
   method run();
      pad1=compare('abc','abc            ');
      pad2=compare('abc','abcdef         ');
      truncate1=compare('abc','abcdef',':');
```

```
      truncate2=compare('abcdef','abc',':');
      blank=compare('','abc',          ':');
      put pad1 pad2 truncate1 truncate2 blank;
   end;
enddata;
run;
quit;

proc print data=test2 noobs;run;quit;
```

Output 7.5 *Results from Using the Colon Modifier to Truncate Strings*

pad1	pad2	truncate1	truncate2	blank
0	-4	0	0	-1

Functions

- "COMPCOST Function" on page 438
- "COMPGED Function" on page 444

COMPBL Function

Removes multiple blanks from a character string.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

COMPBL(*character-expression*)

Required Argument

character-expression
specifies any valid expression that evaluates or can be coerced to a character string and that specifies the character string to compress.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The COMPBL function removes multiple blanks in a character string by translating each occurrence of two or more consecutive blanks into a single blank.

Comparisons

The COMPRESS function removes every occurrence of the specific character from a string. If you specify a blank as the character to remove from the source string, the COMPRESS function is similar to the COMPBL function. However, the COMPRESS function removes all blanks from the source string. The COMPBL function compresses multiple blanks to a single blank and has no effect on a single blank.

Examples

Example 1: Removing Blanks from a String

The following program illustrates the COMPBL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(20) string1 string2;
   method run();
      string1='January       Status';
      string2=compbl(string1);
      put string2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
January Status
```

Example 2: Removing Blanks from a String That Is Passed to the Function

The following program illustrates the COMPBL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data test (overwrite=yes);
   dcl char(18) string1 string2;
   method run();
      string1='125    E. Main St.';
      string2=compbl(string1);
      put string2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
125 E. Main St.
```

See Also

Functions:

- "COMPRESS Function" on page 456

COMPCOST Function

Sets the costs of operations for later use by the COMPGED function.

Syntax

COMPCOST(*operation-1*, *value-1* [..., *operation-n*, *value-n*]);

Required Arguments

operation
is a character constant, variable, or expression that specifies an operation that is performed by the COMPGED function.

value
is a numeric constant, variable, or expression that specifies the cost of the operation that is indicated by the preceding argument.

Restriction Must be an integer that ranges from –32767 to 32767, or a missing value

Details

Computing the Cost of Operations

Each argument that specifies an operation must have a value that is a character string. The character string corresponds to one of the terms that are used to denote an operation that the COMPGED function performs. See "Computing the Generalized Edit Distance" on page 445 to view a table of operations that the COMPGED function uses.

The character strings that specify operations can be in uppercase, lowercase, or mixed case. Blanks are ignored. Each character string must end with an equal sign (=). The following table lists valid values for operations and the default cost of the operations.

Operation	Default Cost
APPEND=	very large
BLANK=	very large
DELETE=	100
DOUBLE=	very large
FDELETE=	equal to DELETE
FINSERT=	equal to INSERT
FREPLACE=	equal to REPLACE
INSERT=	100
MATCH=	0
PUNCTUATION=	very large
REPLACE=	100
SINGLE=	very large
SWAP=	very large
TRUNCATE=	very large

If an operation does not appear in the COMPCOST function, or if the operation appears and is followed by a missing value, that operation is assigned a default cost. A "very large" cost indicates a cost that is sufficiently large that the COMPGED function does not use the corresponding operation.

After your program uses the COMPCOST function, the costs that are specified remain in effect until your program uses the COMPCOST function again, or until the data program that contains the COMPCOST function terminates.

Note: If an FCMP function calls the COMPGED function, then COMPGED is affected by COMPCOST calls within the FCMP function that is processed before the COMPGED processing. If COMPCOST is called outside of the FCMP function, the COMPGED call that is inside the FCMP function is not affected by COMPCOST calls that are outside of the FCMP function.

Abbreviating Character Strings

You can abbreviate character strings. That is, you can use the first one or more letters of a specific operation rather than use the entire term. However, you must use as many letters as necessary to uniquely identify the term. For example, you can specify the INSERT= operation as “in=” and the REPLACE= operation as “r=”. To specify the DELETE= operation or the DOUBLE= operation, you must use the first two letters because both DELETE= and DOUBLE= begin with “d”. The character string must always end with an equal sign.

Example

This example calls the COMPCOST routine to compute the generalized edit distance for the operations that are specified.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testdata /overwrite=yes;
   dcl char string operation;
   method init();
      string='baboon'; operation='match'; output;
      string='xbaboon'; operation='insert'; output;
      string='babon'; operation='delete'; output;
      string='baXoon'; operation='replace'; output;
   end;
enddata;
run;

data mytest /overwrite=yes;
   dcl double ged;
   method run();
      set testdata;
      if _n_ =1 then compcost('insert=', 10, 'DEL=', 11, 'r=', 12);
      ged=compged(string, 'baboon');
      put 'string=' string 'operation=' operation 'ged=' ged;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
string= baboon   operation= match    ged= 0
string= xbaboon  operation= insert   ged= 10
string= babon    operation= delete   ged= 11
string= baXoon   operation= replace  ged= 12
```

COMPFUZZ Function

Performs a fuzzy comparison of two numeric values.

Category: Mathematical

Returned data type: DOUBLE

Syntax

COMPFUZZ(*expression-1*, *expression-2*[, *fuzz*[, *scale*]])

Required Arguments

expression-1
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

expression-2
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Optional Arguments

fuzz

is a nonnegative numeric value that specifies the relative threshold for comparisons. Values that are greater than or equal to one are treated as multiples of the machine precision.

Default 1024

Data type DOUBLE

scale

specifies the scale factor.

Default MAX (ABS (*expression-1*), ABS (*expression-2*))

Data type DOUBLE

Details

The COMPFUZZ function returns the following values if you specify all four arguments:

- -1 if *expression-1* < *expression-2* – threshold
- 0 if ABS(*expression-1* - *expression-2*) ≤ threshold
- 1 if *expression-1* > *expression-2* + threshold

The following relationships exist:

- threshold = *fuzz* * ABS(*scale*) if 0 ≤ *fuzz* < 1
- threshold = *fuzz* * ABS(*scale*) * CONSTANT('MACEPS') if 1 ≤ *fuzz* < 1 / CONSTANT('MACEPS')

COMPFUZZ avoids floating-point underflow or overflow.

Comparisons

The COMPFUZZ function compares two floating-point numbers and returns a value based on the comparison. The ROUND function rounds an argument to a value that is very close to a multiple of a second argument. The result might not be an exact multiple of the second argument.

Example

In floating-point arithmetic, the value of a sum sometimes depends on the order in which the numbers are added. One approximate bound for the floating-point error

in the computation of a sum of *n* numbers, x1 through x*n*, is expressed by the following formula:

```
n * machine_precision * sum (abs(x1) + ... + abs(xn))
```

To compare sums of *n* floating-point numbers with the COMPFUZZ function, you can therefore use *n* as the fuzz value and the sum of the absolute values as the scale factor, as shown in the following DATA step:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x1 x2 x3 x4 sum1 sum2 diff compfuzz1 compfuzz2 scale;
   method run();
      x1 = -1./3.;
      x2 = 22./7.;
      x3 = -1234567891.;
      x4 = 1234567890.;
      /* Add the numbers in two different orders. */
      sum1 = x1 + x2 + x3 + x4;
      sum2 = x4 + x3 + x2 + x1;
      diff = abs(sum1 - sum2);
      put sum1=;
      put sum2=;
      put diff=;
      /* Using only a fuzz value gives the wrong result. The fuzz
value  */
      /* is 8 because there are four numbers in each sum, for a total
of */
      /* eight
numbers.                                                    */
      compfuzz1 = compfuzz(sum1, sum2, 8);
      put 'fuzz only (wrong):        ' compfuzz1=;
      /* Using a fuzz factor and a scale value gives the correct
result. */
      scale = abs(x1) + abs(x2) + abs(x3) + abs(x4);
      compfuzz2 = compfuzz(sum1, sum2, 8, scale);
      put 'fuzz and scale (correct): ' compfuzz2=;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log:

```
sum1=1.80952382087707
sum2=1.8095238095238
diff=1.1353265660929E-8
fuzz only (wrong):         compfuzz1=1
fuzz and scale (correct):  compfuzz2=0
```

COMPGED Function

Returns the generalized edit distance between two strings.

Category: Character

Returned data type: DOUBLE

Syntax

COMPGED(*string-1*, *string-2* [, *cutoff*] [, *modifier(s)*])

Required Arguments

string-1
specifies a character constant, variable, or expression.

string-2
specifies a character constant, variable, or expression.

cutoff
is a numeric constant, variable, or expression.

Note If the actual generalized edit distance is greater than the value of *cutoff*, the value that is returned is equal to the value of *cutoff*.

Tip Using a small value of *cutoff* improves the efficiency of COMPGED if the lengths of the values of *string-1* and *string-2* are long.

Optional Argument

modifier
specifies a character string that can modify the action of the COMPGED function.

The modifiers are not case sensitive. You can use one or more of the following characters as a valid modifier:

i
ignores the case in *string-1* and *string-2*.

l
removes leading blanks in *string-1* and *string-2* before comparing the values.

n
removes quotation marks from any argument that is an n-literal and ignores the case of *string-1* and *string-2*.

:
(colon) truncates the longer of *string-1* or *string-2* to the length of the shorter string, or to 1, whichever is greater.

> **TIP** COMPGED ignores blanks that are used as modifiers.

Arguments

Details

The Order in Which Modifiers Appear

The order in which the modifiers appear in the COMPGED function is relevant.

- "LN" first removes leading blanks from each string, and then removes quotation marks from n-literals.
- "NL" first removes quotation marks from n-literals, and then removes leading blanks from each string.

Definition of Generalized Edit Distance

Generalized edit distance is a generalization of Levenshtein edit distance, which is a measure of dissimilarity between two strings. The Levenshtein edit distance is the number of deletions, insertions, or replacements of single characters that are required to transform *string-1* into *string-2*.

Computing the Generalized Edit Distance

The COMPGED function returns the generalized edit distance between *string-1* and *string-2*. The generalized edit distance is the minimum-cost sequence of operations for constructing *string-1* from *string-2*.

The algorithm for computing the sum of the costs involves a pointer that points to a character in *string-2* (the input string). An output string is constructed by a sequence of operations that might advance the pointer, add one or more characters to the output string, or both. Initially, the pointer points to the first character in the input string, and the output string is empty.

The operations and their costs are described in the following table.

Operation	Default Cost in Units	Description of Operation
APPEND	50	When the output string is longer than the input string, add any one character to the end of the output string without moving the pointer.
BLANK	10	Perform any of these actions: ■ Add one space character to the end of the output string without moving the pointer. ■ When the character at the pointer is a space character, advance the pointer by one position without changing the output string. ■ When the character at the pointer is a space character, add one space character to the end of the output string and advance the pointer by one position. If the cost for BLANK is set to 0 by the COMPCOST function, the COMPGED function removes all space characters from both strings before beginning the comparison.
DELETE	100	Advance the pointer by one position without changing the output string.
DOUBLE	20	Add the character at the pointer to the end of the output string without moving the pointer.
FDELETE	200	When the output string is empty, advance the pointer by one position without changing the output string.
FINSERT	200	When the pointer is in position one, add any one character to the end of the output string without moving the pointer.
FREPLACE	200	When the pointer is in position one and the output string is empty, add any one character to the end of the

Operation	Default Cost in Units	Description of Operation
		output string and advance the pointer by one position.
INSERT	100	Add any one character to the end of the output string without moving the pointer.
MATCH	0	Copy the character at the pointer from the input string to the end of the output string and advance the pointer by one position.
PUNCTUATION	30	Perform any of these actions: ■ Add one punctuation character to the end of the output string without moving the pointer. ■ When the character at the pointer is a punctuation character, advance the pointer by one position without changing the output string. ■ When the character at the pointer is a punctuation character, add one punctuation character to the end of the output string and advance the pointer by one position. If the cost for PUNCTUATION is set to 0 by the COMPCOST function, the COMPGED function removes all punctuation characters from both strings before beginning the comparison.
REPLACE	100	Add any one character to the end of the output string and advance the pointer by one position.
SINGLE	20	When the character at the pointer is the same as the character that follows in the input string, advance the pointer by one position without changing the output string.
SWAP	20	Copy the character that follows the pointer from the input string to the output string. Then copy the

Operation	Default Cost in Units	Description of Operation
		character at the pointer from the input string to the output string. Advance the pointer two positions.
TRUNCATE	10	When the output string is shorter than the input string, advance the pointer by one position without changing the output string.

To set the cost of the string operations, you can use the COMPCOST function or use default costs. If you use the default costs, the values that are returned by COMPGED are approximately 100 times greater than the values that are returned by COMPLEV.

Examples of Errors

The rationale for determining the generalized edit distance is based on the number and types of typographical errors that can occur. COMPGED assigns a cost to each error and determines the minimum sum that could be incurred. Some types of errors can be more serious than others. For example, inserting an extra letter at the beginning of a string might be more serious than omitting a letter from the end of a string. For another example, if you enter a word or phrase that exists in *string-2* and introduce a typographical error, you might produce *string-1* instead of *string-2*.

Making the Generalized Edit Distance Symmetric

Generalized edit distance is not necessarily symmetric. That is, the value that is returned by `COMPGED(string1, string2)` is not always equal to the value that is returned by `COMPGED(string2, string1)`. To make the generalized edit distance symmetric, use the COMPCOST function to assign equal costs to the operations within each of these pairs:

- INSERT, DELETE
- FINSERT, FDELETE
- APPEND, TRUNCATE
- DOUBLE, SINGLE

Comparisons

You can compute the Levenshtein edit distance by using the COMPLEV function. You can compute the generalized edit distance by using the COMPCOST and COMPGED functions. Computing generalized edit distance requires considerably more computer time than computing the Levenshtein edit distance. But generalized edit distance usually provides a more useful measure than the Levenshtein edit distance for applications such as fuzzy file merging and text mining.

Note: When called from a DS2 program, the following FCMP functions do not honor seed values that are set in the DS2 program.

COMPCOST

COMPGED

RAND

STREAMINIT

In a DATA step, all random numbers from RAND are drawn from the same stream by default, but you can create multiple independent streams by using the CALL STREAM routine.

In PROC DS2, as a result of an unexpected feature, random numbers from RAND that are called inside an FCMP package come from a separate stream. To get reproducible random numbers, use the CALL STREAMINIT routine inside each FCMP function that calls RAND. To get independent streams, also use the CALL STREAM routine inside each FCMP function that calls RAND. If you do so, the results from DS2 will be consistent with a DATA step and with future releases. For an example, see "Considerations and Limitations When Using the FCMP Package" in *SAS DS2 Programmer's Guide*.

Example

This example uses the default costs to calculate the generalized edit distance.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
/**** input data ****/
data testdata(overwrite=yes);
   dcl char string1 string2;
   dcl char(30) operation;
   method init();
      string1='baboon';   string2='baboon';   operation='match';
output;
      string1='baXboon';  string2='baboon';   operation='insert';
output;
      string1='baoon';    string2='baboon';   operation='delete';
output;
      string1='baXoon';   string2='baboon';   operation='replace';
output;
      string1='baboonX';  string2='baboon';   operation='append';
output;
      string1='baboo';    string2='baboon';   operation='truncate';
output;
      string1='babboon';  string2='baboon';   operation='double';
output;
      string1='babon';    string2='baboon';   operation='single';
output;
      string1='baobon';   string2='baboon';   operation='swap'; output;
```

```
      string1='bab oon';  string2='baboon';   operation='blank';
output;
      string1='bab,oon';  string2='baboon';   operation='punctuation';
         output;
      string1='bXaoon';   string2='baboon';   operation='insert
+delete';
         output;
      string1='bXaYoon';  string2='baboon';   operation='insert
+replace';
         output;
      string1='bXoon';    string2='baboon';   operation='delete
+replace';
         output;
      string1='Xbaboon';  string2='baboon';   operation='finsert';
         output;
      string1='aboon';    string2='baboon';
         operation='trick question: swap+delete'; output;
      string1='Xaboon';   string2='baboon';   operation='freplace';
output;
      string1='axoon';    string2='baboon';
         operation='fdelete+replace'; output;
      string1='axoo';     string2='baboon';
         operation='fdelete+replace+truncate'; output;
      string1='axon';     string2='baboon';
         operation='fdelete+replace+single'; output;
      string1='baby';     string2='baboon';
         operation='replace+truncate*2'; output;
      string1='balloon';  string2='baboon';
         operation='replace+insert'; output;
   end;
enddata;
run;

/**** comparison code *****/
data mytest (overwrite=yes) noobs;
   dcl double ged;
   method run();
      set testdata;
      ged=compged(string1, string2);
      put 'string1=' string1 'string2=' string2 'operation='
          operation 'ged=' ged;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
string1= baboon   string2= baboon   operation= match                          ged= 0
string1= baXboon  string2= baboon   operation= insert                         ged= 100
string1= baoon    string2= baboon   operation= delete                         ged= 100
string1= baXoon   string2= baboon   operation= replace                        ged= 100
string1= baboonX  string2= baboon   operation= append                         ged= 50
string1= baboo    string2= baboon   operation= truncate                       ged= 10
string1= babboon  string2= baboon   operation= double                         ged= 20
string1= babon    string2= baboon   operation= single                         ged= 20
string1= baobon   string2= baboon   operation= swap                           ged= 20
string1= bab oon  string2= baboon   operation= blank                          ged= 10
string1= bab,oon  string2= baboon   operation= punctuation                    ged= 30
string1= bXaoon   string2= baboon   operation= insert+delete                  ged= 200
string1= bXaYoon  string2= baboon   operation= insert+replace                 ged= 200
string1= bXoon    string2= baboon   operation= delete+replace                 ged= 200
string1= Xbaboon  string2= baboon   operation= finsert                        ged= 200
string1= aboon    string2= baboon   operation= trick question: swap+delete    ged= 120
string1= Xaboon   string2= baboon   operation= freplace                       ged= 200
string1= axoon    string2= baboon   operation= fdelete+replace                ged= 300
string1= axoo     string2= baboon   operation= fdelete+replace+truncate       ged= 310
string1= axon     string2= baboon   operation= fdelete+replace+single         ged= 320
string1= baby     string2= baboon   operation= replace+truncate*2             ged= 120
string1= balloon  string2= baboon   operation= replace+insert                 ged= 200
```

- “COMPLEV Function” on page 451

COMPLEV Function

Returns the Levenshtein edit distance between two strings.

Category: Character

Returned data type: DOUBLE

Syntax

COMPLEV(*string-1*, *string-2* [, *cutoff*] [, *modifier(s)*])

Required Arguments

string-1
specifies a character constant, variable, or expression.

string-2
specifies a character constant, variable, or expression.

Optional Arguments

cutoff
specifies a numeric constant, variable, or expression.

Note If the actual Levenshtein edit distance is greater than the value of *cutoff*, the value that is returned is equal to the value of *cutoff*.

Tip Using a small value of *cutoff* improves the efficiency of COMPLEV if the length of the values of *string-1* and *string-2* are long.

modifier
specifies a character string that can modify the action of the COMPLEV function. The modifiers are not case sensitive.

You can use one or more of the following characters as a valid modifier:

i
ignores the case in *string-1* and *string-2*.

l
removes leading blanks in *string-1* and *string-2* before comparing the values.

n
removes quotation marks from any argument that is an n-literal and ignores the case of *string-1* and *string-2*.

:
(colon) truncates the longer of *string-1* or *string-2* to the length of the shorter string, or to 1, whichever is greater.

> **TIP** COMPLEV ignores blanks that are used as modifiers.

Details

The order in which the modifiers appear in the COMPLEV function is relevant.

- "LN" first removes leading blanks from each string, and then removes quotation marks from n-literals.
- "NL" first removes quotation marks from n-literals, and then removes leading blanks from each string.

The COMPLEV function ignores trailing blanks.

COMPLEV returns the Levenshtein edit distance between *string-1* and *string-2*. The Levenshtein edit distance is the number of insertions, deletions, or replacements of single characters that are required to convert one string to the other. Levenshtein edit distance is symmetric. That is, `COMPLEV(string-1,string-2)` is the same as `COMPLEV(string-2,string-1)`.

Comparisons

The Levenshtein edit distance that is computed by COMPLEV is a special case of the generalized edit distance that is computed by COMPGED.

COMPLEV executes much more quickly than COMPGED.

Example

This example compares two strings by computing the Levenshtein edit distance.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/**** input data ****/
proc ds2;
data testdata (overwrite=yes);
   dcl char string1 string2 modifier;
   method init();
      string1='12345678'; string2='12345678'; output;
      string1='abc'; string2='abxc'; output;
      string1='ac'; string2='abc'; output;
      string1='aXc'; string2='abc'; output;
      string1='aXbZc'; string2='abc'; output;
      string1='aXYZc'; string2='abc'; output;
      string1='WaXbYcZ'; string2='abc'; output;
      string1='XYZ'; string2='abcdef'; output;
      string1='aBc'; string2='abc'; output;
      string1='aBc'; string2='AbC'; modifier='i'; output;
      string1='  abc'); string2='abc'; modifier=''; output;
      string1='  abc'); string2='abc';  modifier='l'; output;
      string1='AxC'; string2=n'abc'; modifier=''; output;
      string1='AxC'; string2=n'abc'; modifier='n'; output;
   end;
enddata;
run;
quit;

/**** comparison code *****/
proc ds2;
data test (overwrite=yes);
   dcl double result;
   method run();
      set testdata;
      result=complev(string1, string2, modifier);
      put 'string1=' string1 'string2=' string2 'modifier=' modifier
         'result=' result;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
string1= 12345678 string2= 12345678 modifier=          result= 0
string1= abc      string2= abxc     modifier=          result= 1
string1= ac       string2= abc      modifier=          result= 1
string1= aXc      string2= abc      modifier=          result= 1
string1= aXbZc    string2= abc      modifier=          result= 2
string1= aXYZc    string2= abc      modifier=          result= 3
string1= WaXbYcZ  string2= abc      modifier=          result= 4
string1= XYZ      string2= abcdef   modifier=          result= 6
string1= aBc      string2= abc      modifier=          result= 1
string1= aBc      string2= AbC      modifier= i        result= 0
string1=   abc    string2= abc      modifier=          result= 2
string1=   abc    string2= abc      modifier= l        result= 0
string1= AxC      string2= abc      modifier=          result= 3
string1= AxC      string2= abc      modifier= n        result= 1
```

COMPOUND Function

Returns compound interest parameters.

Category: Financial

Returned data type: DOUBLE

Syntax

COMPOUND(*a*, *f*, *r*, *n*)

Required Arguments

a

specifies the initial amount.

Range $a \geq 0$

Data type DOUBLE

f

specifies the future amount (at the end of *n* periods).

Range $f \geq 0$

Data type DOUBLE

r

specifies the periodic interest rate expressed as a fraction.

Range $r \geq 0$

Data type DOUBLE

n

specifies the number of compounding periods.

Range $n \geq 0$

Data type DOUBLE

Details

The COMPOUND function returns the missing argument in the list of four arguments from a compound interest calculation. The arguments are related by the following equation:

$$f = a(1 + r)^n$$

One missing argument must be provided. A compound interest parameter is then calculated from the remaining three values. No adjustment is made to convert the results to round numbers.

If n=0, then

$$f = a$$

and

$$(1 + r)^n$$

is equal to 1.

Note: If you choose *r* as your missing value, then COMPOUND returns an error.

Example

The accumulated value of an investment of $2000 at a nominal annual interest rate of 9%, compounded monthly after 30 months, can be calculated using this program. The second argument has been set to missing, indicating that the future amount is to be calculated. The 9% nominal annual rate has been converted to a monthly rate

of 0.09/12. The rate argument is the fractional (not the percentage) interest rate per compounding period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double future;
   method run();
      future=compound(2000, ., 0.09/12, 30);
      put future;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2502.54352764668
```

COMPRESS Function

Returns a character string with specified characters removed from the original string.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

COMPRESS(*character-expression*[, *character-list-expression*] [, *modifier(s)*])

Required Argument

character-expression
specifies any valid expression that evaluates to a character expression and from which specified characters are to be removed.

Requirement: Enclose a literal string of characters in single quotation marks.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Arguments

character-list-expression
specifies a variable or any valid expression that initializes a list of characters.

By default, the characters in this list are removed from *character-expression*.

Requirement Enclose a literal string of characters in single quotation marks.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

modifier
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COMPRESS function. Blanks are ignored. The modifiers are not case sensitive.

The following characters can be used as modifiers:

A
adds alphabetic characters to the list of characters.

C
adds control characters to the list of characters.

D
adds digits to the list of characters.

F
adds the underscore character and English letters to the list of characters.

G
adds graphic characters to the list of characters. Graphic characters are characters in the current locale that, when printed, produce an image on paper.

L
adds a horizontal tab to the list of characters.

I
ignores the case of the characters to be kept or removed.

K
keeps the characters in the list instead of removing them.

l
adds lowercase letters to the list of characters.

N
adds digits, the underscore character, and English letters to the list of characters.

O
processes the second and third arguments once rather than every time the COMPRESS function is called. Using the O modifier in the DATA step (excluding WHERE clauses), or in the SQL procedure, can make COMPRESS run much faster when you call it in a loop where the second and third arguments do not change.

P
adds punctuation marks to the list of characters.

S
adds space characters (blank, horizontal tab, vertical tab, carriage return, line feed, form feed, and NBSP ('A0'x, or 160 decimal ASCII) to the list of characters.

T
trims trailing blanks from the first and second arguments.

U
adds uppercase letters to the list of characters.

W
adds printable characters to the list of characters.

X
adds hexadecimal characters to the list of characters.

Tip If the modifier is a constant, enclose it in single quotation marks. Specify multiple constants in a single set of quotation marks. Modifier can also be expressed as a variable or an expression.

Details

The COMPRESS function compiles a list of characters to keep or remove, comprising the characters in the second argument plus any types of characters that are specified by the modifiers.

Based on the number of arguments, the COMPRESS function works as follows:

Number of Arguments	Results
Only the first argument, *source*	All blanks have been removed. If the argument is completely blank, then the result is a string with a length of zero. If you assign the result to a character variable with a fixed length, then the value of that variable is padded with blanks to fill its defined length.
Two arguments, *source* and *chars*	All characters that appear in the second argument are removed from the result.
Three arguments, *source*, *chars*, and *modifier* (or *modifiers*)	The K modifier (specified in the third argument) determines whether the characters in the second argument are kept or removed from the result.

Here is an example that illustrates the effect of the third argument. The D modifier specifies digits. Both of the following function calls remove digits from the result:

```
compress(source, "1234567890");
compress(source, '', "d");
```

To remove digits and plus or minus signs, you could use the following function call:

```
COMPRESS(source, "1234567890+-");
compress(source, "+-", "d");
```

The COMPRESS function allows null or missing (".") arguments in the second argument. A null or missing argument is treated as a string that has a length of zero. A string that has length 0 is an empty string.

```
compress(source, null);
compress(source, '');
```

Examples

Example 1: Compressing Blanks

This program illustrates how to remove blanks from a character string.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char a b;
   method run();
      a='AB C D ';
      b=compress(a);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
ABCD
```

Example 2: Compressing Uppercase Letters

This program illustrates how to remove uppercase letters from a character string.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char a b;
   method run();
      a='AB C D';
```

```
      b=compress(a, 'A');
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
B C D
```

Example 3: Compressing a String and Returning a Length of 0

This program illustrates how to remove uppercase letters from a character string.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) x;
   dcl double l;
   method run();
      x=' ';
      l=length(compress(x));
      put l=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
l=0
```

Example 4: Compressing Vowels

This example illustrates how to remove vowels from a string:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(32) x;
   dcl char(32) y;
   method run();
      x='123-4567-8901 e 234-5678-9012 i';
      y=compress(x,'aeiou');
      put y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
123-4567-8901  234-5678-9012
```

Example 5: Compressing Lowercase Letters by Using a Modifier

This example compresses the uppercase letters using the list of characters to be removed and any lowercase letters that are specified by the modifier “l”.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(32) x y;
   method run();
      x='123-4567-8901 B 234-5678-9012 c';
      y=compress(x, 'ABCD', 'l');
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=123-4567-8901  234-5678-9012
```

Example 6: Compressing Space Characters by Using a Modifier

This example illustrates removing spaces from the given string by using the modifier “s”.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) x y;
   method run();
      x='1 2 3 4 5';
      y=compress(x, '', 's');
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=12345
```

Example 7: Keeping Characters in the List by Using a Modifier

This example illustrates keeping characters in the specified string by using the modifier “k”.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(26) x y;
   method run();
      x='Math A English B Physics A';
      y=compress(x, 'ABCD', 'k');
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
y=ABA
```

CONSTANT Function

Computes machine and mathematical constants.

Category: Mathematical

Returned data type: DOUBLE

Syntax

CONSTANT(*constant*[, *parameter*])

Required Argument

constant
is a character constant, variable, or expression that identifies the constant to be returned.

Valid constants are as follows:

Constant	Description
'E'	The natural base
'EULER'	Euler constant
'PI'	Pi
'EXACTINT' [,nbytes]	Exact integer
'BIG'	The largest double-precision number
'LOGBIG' [,base]	The log with respect to *base* of BIG
'SQRTBIG'	The square root of BIG
'SMALL'	The smallest double-precision number
'LOGSMALL' [,base]	The log with respect to *base* of SMALL
'SQRTSMALL'	The square root of SMALL
'MACEPS'	Machine precision constant
'LOGMACEPS' [,base]	The log with respect to *base* of MACEPS
'SQRTMACEPS'	The square root of MACEPS

Optional Argument

parameter
is a numeric parameter that can be used as an optional argument with some of the constants specified in *constant*. When used, *parameter* alters the functionality of the CONSTANT function.

Details

Overview

CAUTION
In some operating environments, the run-time library might have limitations that prevent the use of the full range of floating-point numbers that the hardware provides. In such cases, the CONSTANT function attempts to return values that are compatible with the limitations of the run-time library. For example, if the run-

time library cannot compute `EXP(LOG(CONSTANT('BIG')))`, then `CONSTANT('LOGBIG')` does not return the same value as `LOG(CONSTANT('BIG'))`, but returns a value such that `EXP(CONSTANT('LOGBIG'))` can be computed.

The Natural Base

CONSTANT('E')

The natural base is described by the following equation:

$$\lim_{x \to 0} (1+x)^{\frac{1}{x}} \approx 2.718281828459045$$

Euler Constant

CONSTANT('EULER')

Euler's constant is described by the following equation:

$$\lim_{n \to \infty} \left\{ \sum_{j=1}^{j=n} \frac{1}{j} - \log(n) \right\} \approx 0.577215664901532860$$

Pi

CONSTANT('PI')

Pi is the ratio between the circumference and the diameter of a circle. Many expressions exist for computing this constant. One such expression for the series is described by the following equation:

$$4 \sum_{j=0}^{j=\infty} \frac{(-1)^j}{2j+1} \approx 3.14159265358979323846$$

Exact Integer

CONSTANT('EXACTINT'[, *nbytes*])

Arguments

nbytes
is a numeric value that is the number of bytes.

Default 8

Range $2 \le nbytes \le 8$

The exact integer is the largest integer *k* such that all integers less than or equal to *k* in absolute value have an exact representation in a SAS numeric variable of length *nbytes*. This information can be useful to know before you trim a SAS numeric variable from the default 8 bytes of storage to a lower number of bytes to save storage.

The Largest Double-Precision Number

CONSTANT('BIG')

This case returns the largest double-precision floating-point number (8-bytes) that is representable on your computer.

The Logarithm of BIG

CONSTANT('LOGBIG'[, *base*])

Arguments

base
is a numeric value that is the base of the logarithm.

Default the natural base, E

Restriction The *base* that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to *base* of the largest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to exponentiate the given *base* raised to a power less than or equal to CONSTANT('LOGBIG', *base*) by using the power operation (**) without causing any overflows.

It is safe to exponentiate any floating-point number less than or equal to CONSTANT('LOGBIG') by using the exponential function, EXP, without causing any overflows.

The Square Root of BIG

CONSTANT('SQRTBIG')

This case returns the square root of the largest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to square any floating-point number less than or equal to CONSTANT('SQRTBIG') without causing any overflows.

The Smallest Double-Precision Number

CONSTANT('SMALL')

This case returns the smallest double-precision floating-point number (8-bytes) that is representable on your computer.

The Logarithm of SMALL

CONSTANT('LOGSMALL'[, *base*])

Arguments

base
is a numeric value that is the base of the logarithm.

Default the natural base, E

Restriction The *base* that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to *base* of the smallest double-precision floating-point number (8-bytes) that is representable on your computer.

It is safe to exponentiate the given *base* raised to a power greater than or equal to CONSTANT('LOGSMALL', *base*) by using the power operation (**) without causing any underflows or 0.

It is safe to exponentiate any floating-point number greater than or equal to CONSTANT('LOGSMALL') by using the exponential function, EXP, without causing any underflows or 0.

The Square Root of SMALL

CONSTANT('SQRTSMALL')

This case returns the square root of the smallest double-precision floating-point number (8-bytes) that is representable on the computer.

It is safe to square any floating-point number greater than or equal to CONSTANT('SQRTBIG') without causing any underflows or 0.

Machine Precision

CONSTANT('MACEPS')

This case returns the smallest double-precision floating-point number (8-bytes) $\varepsilon = 2^{-j}$ for some integer *j*, such that $1 + \varepsilon > 1$.

This constant is important in finite precision computations.

The Logarithm of MACEPS

CONSTANT('LOGMACEPS'[, *base*])

Arguments

base
is a numeric value that is the base of the logarithm.

Default the natural base, E

Restriction The *base* that you specify must be greater than the value of 1+SQRTMACEPS.

This case returns the logarithm with respect to *base* of CONSTANT('MACEPS').

The Square Root of MACEPS

CONSTANT('SQRTMACEPS')

This case returns the square root of CONSTANT('MACEPS').

Example

The following program uses the CONSTANT function to return values for various constants.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
 dcl double a b c d e f g h i j k l m;
   method run();
      a=constant('E');
      b=constant('EULER');
      c=constant('PI');
      d=constant('EXACTINT');
      e=constant('BIG');
      f=constant('LOGBIG');
      g=constant('SQRTBIG');
      h=constant('SMALL');
      i=constant('LOGSMALL');
      j=constant('SQRTSMALL');
      k=constant('MACEPS');
      l=constant('LOGMACEPS');
      m=constant('SQRTMACEPS');
      put  'a= ' a;
      put 'b= ' b;
      put 'c= ' c;
      put 'd= ' d;
      put 'e= ' e;
      put 'f= ' f;
      put 'g= ' g;
      put 'h= ' h;
      put 'i= ' i;
      put 'j= ' j;
      put 'k= ' k;
      put 'l= ' l;
      put 'm= ' m;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=  2.71828182845904
b=  0.57721566490153
c=  3.14159265358979
d=  9007199254740992
e=  1.7976931348623E308
f=  709.782712893383
g=  1.3407807929942E154
h=  2.2250738585072E-308
i=  -708.396418532264
j=  1.49166814624E-154
k=  2.2204460492503E-16
l=  -36.0436533891171
m=  1.4901161193847E-8
```

CONVX Function

Returns the convexity for an enumerated cash flow.

Category: Financial

Returned data type: DOUBLE

Syntax

CONVX(*y*, *f*, *c(1)*, ..., *c(k)*)

Required Arguments

y

specifies the effective per-period yield-to-maturity.

Range $0 < y < 1$

Data type DOUBLE

Tip If you express *y* as a fraction, the dividend must be written as a decimal value. In DS2, integer division results in a value of zero. Zero is converted to a DOUBLE and is passed as the first argument to the CONVX function. The CONVX function returns missing when a zero is passed as the first parameter.

f

specifies the frequency of cash flows per period.

Range $f > 0$

Data type DOUBLE

c(1), ... , c(k)

specifies a list of cash flows.

Data type DOUBLE

Details

The CONVX function returns the value from the following equation.

$$C = \sum_{k=1}^{K} \frac{k(k+f)\dfrac{c(k)}{(1+y)^{\frac{k}{f}}}}{P\left((1+y)^2\right)f^2}$$

The following relationship applies to the preceding equation:

$$P = \sum_{k=1}^{K} \frac{c(k)}{(1+y)^{\frac{k}{f}}}$$

Example: Using the CONVX Function

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test /overwrite=yes;
   dcl double c;
   method run();
      c=convx(1./20,.1,.33,.44,.55,.49,.50,.22,.4,.8,.01,.36,.2,.4);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
976.941120481246
```

See Also

Functions:

- “CONVXP Function” on page 470

CONVXP Function

Returns the convexity for a periodic cash flow stream, such as a bond.

Category: Financial

Returned data type: DOUBLE

Syntax

CONVXP(*A*, *c*, *n*, *K*, k_0, *y*)

Required Arguments

A

specifies the par value.

Ranges $A > 0$

$A > 0$

Data type DOUBLE

c

specifies the nominal per-period coupon rate, expressed as a decimal.

Range $0 \le c < 1$

Data type DOUBLE

n

specifies the number of coupons per period.

Range $n > 0$

Data type DOUBLE

K

specifies the number of remaining coupons.

Range $K > 0$

Data type DOUBLE

k_0

specifies the time from the present date to the first coupon date, expressed in terms of the number of periods.

Ranges $0 < k_0 \leq \frac{1}{n}$

$0 < k_0 \leq 1/n$

Data type DOUBLE

y

specifies the nominal per-period yield-to-maturity.

Range $y > 0$

Data type DOUBLE

Details

The CONVXP function returns the value from the following equation.

$$C = \frac{1}{n^2}\left(\frac{\sum_{k=1}^{K} t_k(t_k+1)\frac{c(k)}{\left(1+\frac{y}{n}\right)^{t_k}}}{P\left(1+\frac{y}{n}\right)^2}\right)$$

The following relationships apply to the preceding equation:

$$t_k = nk_0 + k - 1$$

$$c(k) = \frac{c}{n}A \quad for\ k = 1, \ldots, K-1$$

$$c(K) = \left(1+\frac{c}{n}\right)A$$

The following relationship applies to the preceding equation:

$$P = \sum_{k=1}^{K} \frac{c(k)}{\left(1+\frac{y}{n}\right)^{t_k}}$$

Example: Computing the Convexity of a Bond

In the following program, the CONVXP function returns the convexity of a bond that has a face value of 1000, an annual coupon rate of 0.01, 4 coupons per year, and 14 remaining coupons. The time from settlement date to next coupon date is 0.165, and the annual yield-to-maturity is 0.08.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data test/overwrite=yes;
   dcl double c;
   method run();
      c=convxp(1000,.01,4,14,.33/2,.08);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
11.7290019868346
```

See Also

Functions:

- "CONVX Function" on page 468

COS Function

Returns the cosine in radians.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

COS(*expression*)

Required Argument

expression
is any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the COS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x y z;
   method run();
      x=cos(0.5);
      y=cos(0);
      z=cos(3.14159/3);
      put x;
      put y;
      put z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
0.87758256189037
1
0.50000076602519
```

COSH Function

Returns the hyperbolic cosine in radians.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

COSH(*expression*)

Required Argument

expression
is any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The COSH function returns the hyperbolic cosine of the argument, given by the following equation.

$$(e^{argument} + e^{-argument})/2$$

Example

The following program illustrates the COSH function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double w x y z;
   method run();
      w=cosh(0);
      x=cosh(-5);
      y=cosh(4.37);
      z=cosh(0.5);
      put w;
      put x;
      put y;
      put z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
74.2099485247878
39.5281414700662
1.12762596520638
```

COT Function

Returns the cotangent.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

COT(*argument*)

Required Argument

argument
specifies a numeric constant, variable, or expression and is expressed in radians.

Restriction *argument* cannot be 0 or a multiple of PI.

Comparisons

The COT function is related to the TAN function in this way:

```
cot(x)=1/tan(x)
```

Example

The following program illustrates the COMB function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x y z;
   method run();
      x=cot(0.5);
      y=cot(1);
      z=cot(3.14159/3);
      put x;
      put y;
      put z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1.83048772171245
0.64209261593433
0.57735144856346
```

Note: If you use `x=cot(0);`, then the COT function returns a missing value, and a note is written to the log that indicates you entered an invalid argument to the function. This is the correct behavior.

COUNT Function

Counts the number of times that a specified substring appears within a character string.

Category: Character

Returned data type: DOUBLE

Syntax

COUNT(*string*, *substring*[, *modifiers*])

Required Arguments

string
specifies a character constant, variable, or expression in which substrings are to be counted.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

substring
specifies the character constant, variable, or expression to be counted in *string*.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

Optional Argument

modifiers
is a character constant, variable, or expression that specifies one or more modifiers.

The following characters, in uppercase or lowercase, can be used as modifiers:

I
ignores character case during the count. If this modifier is not specified, COUNT counts only character substrings with the same case as the characters in *substring*.

T
trims trailing blanks from *string* and *substring*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip If *modifiers* is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks. *Modifiers* can also be expressed as a variable or an expression.

Details

The Basics

The COUNT function searches *string*, from left to right, for the number of occurrences of the specified *substring*, and returns that number of occurrences. If the substring is not found in *string*, COUNT returns a value of 0.

CAUTION
If two occurrences of the specified substring overlap in the string, the result is undefined. For example, COUNT('boobooboo', 'booboo') might return either a 1 or a 2.

Comparisons

The COUNT function counts substrings of characters in a character string, whereas the COUNTC function counts individual characters in a character string.

Example

The following program illustrates the COUNT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data test (overwrite=yes);
   dcl char(50) xyz expression1 expression2 expression3;
   dcl double howmanythis howmanyis howmanythis_i howmanyis_i
howmanyis_it;
   dcl char(45) variable1 variable3;
   dcl char(3) variable2;
   method run();
      xyz='This is a thistle? Yes, this is a thistle.';
      howmanythis=count(xyz,'this');
      put howmanythis;
      xyz='This is a thistle? Yes, this is a thistle.';
      howmanyis=count(xyz,'is');
      put howmanyis;
      howmanythis_i=count('This is a thistle? Yes, this is a thistle.',
          'this', 'i');
      put howmanythis_i;
      variable1='This is a thistle? Yes, this is a thistle.';
      variable2='is ';
      variable3='i';
      howmanyis_i=count(variable1,variable2,variable3);
      put howmanyis_i;
      expression1='This is a thistle? ' || 'Yes, this is a thistle.';
      expression2=kscan('This is',2) || '     ';
      expression3=compress('i     ' || '     t');
      howmanyis_it=count(expression1,expression2,expression3);
      put howmanyis_it;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
3
6
4
4
6
```

- “INDEX Function” on page 713

COUNTC Function

Counts the number of characters in a string that appear or do not appear in a list of characters.

Category: Character

Returned data type: DOUBLE

Syntax

COUNTC(*string*, *charlist*[, *modifiers*])

Required Arguments

string
specifies a character constant, variable, or expression in which characters are counted.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

charlist
specifies a character constant, variable, or expression that initializes a list of characters. COUNTC counts characters in this list, provided that you do not specify the V modifier in the *modifiers* argument. If you specify the V modifier, then all characters that are not in this list are counted. You can add more characters to the list by using other modifiers.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tips: Enclose a literal string of characters in quotation marks.

If there are no characters in the list after processing the modifiers, COUNTC returns 0.

Optional Argument

modifiers
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTC function. Blanks are ignored. The following characters, in uppercase or lowercase, can be used as modifiers: A (adds alphabetic characters to the list), C (adds control characters), and D (adds digits). Additional modifiers are available. See *SAS DS2 Language Reference* for more information.

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTC function. Blanks are ignored.

The following characters, in uppercase or lowercase, can be used as modifiers:

A
adds alphabetic characters to the list of characters.

B
scans *string* from right to left, instead of from left to right.

C
adds control characters to the list of characters.

D
adds digits to the list of characters.

F
adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.

G
adds graphic characters to the list of characters.

H
adds a horizontal tab to the list of characters.

I
ignores case.

L
adds lowercase letters to the list of characters.

N
adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.

O
processes the *charlist* and *modifier* arguments only once, at the first call to this instance of COUNTC. If you change the value of *charlist* or *modifier* in subsequent calls, the change might be ignored by COUNTC.

P
adds punctuation marks to the list of characters.

S
adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).

T
trims trailing blanks from *string* and *chars*. If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the COUNTC function with the T modifier.

U
adds uppercase letters to the list of characters.

V
counts characters that do not appear in the list of characters. If you do not specify this modifier, then COUNTC counts characters that do appear in the list of characters.

W
adds printable characters to the list of characters.

X
adds hexadecimal characters to the list of characters.

Data type CHAR, VARCHAR

Tip If *modifier* is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks.

Details

The COUNTC function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. If there are no characters in the list of characters to be counted, COUNTC returns zero.

Note: Remember that strings with a CHAR data type are always padded out with blanks to the declared length. Strings with a VARCHAR data type return the length of the actual string instead of the declared length.

Comparisons

The COUNTC function counts individual characters in a character string, whereas the COUNT function counts substrings of characters in a character string.

Example

The following program uses the COUNTC function with and without modifiers to count the number of characters in a string.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(24) string a b b_i abc_i abc_iv abc_ivt;
      method run();
         string  = 'Baboons Eat Bananas     ';
         a= countc(string, 'a');
         b= countc(string,'b');
```

```
            b_i= countc(string,'b','i');
            abc_i= countc(string,'abc','i');
         /* Scan string for characters that are not "a", "b", */
         /* and "c", ignore case, (and include blanks).       */
            abc_iv  = countc(string,'abc','iv');
         /* Scan string for characters that are not "a", "b", */
         /* and "c", ignore case, and trim trailing blanks.   */
            abc_ivt = countc(string,'abc','ivt');
         end;
   enddata;
   run;
   quit;
   proc print data=test; run;
```

Output 7.6 *Results from Using the COUNTC Function With and Without Modifiers*

Obs	string	a	b	b_i	abc_i	abc_iv	abc_ivt
1	Baboons Eat Bananas	5	1	3	8	16	11

COUNTW Function

Counts the number of words in a character string.

Category: Character

Returned data type: DOUBLE

Syntax

COUNTW(*string*[, *chars*[, *modifiers*]])

Required Argument

string
specifies a character constant, variable, or expression in which words are counted.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Optional Arguments

chars
specifies an optional character constant, variable, or expression that initializes a list of characters. The characters in this list are the delimiters that separate words, provided that you do not use the K modifier in the *modifier* argument. If you specify the K modifier, then all characters that are not in this list are delimiters. You can add more characters to the list by using other modifiers.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

modifiers
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTW function. The following

characters, in uppercase or lowercase, can be used as modifiers: A (adds alphabetic characters to the list), C (adds control characters), and D (adds digits). Additional modifiers are available. See *SAS DS2 Language Reference* for more information.

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the COUNTW function.

The following characters, in uppercase or lowercase, can be used as modifiers:

A
adds alphabetic characters to the list of characters.

B
scans *string* from right to left, instead of from left to right.

C
adds control characters to the list of characters.

D
adds digits to the list of characters.

F
adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.

G
adds graphic characters to the list of characters.

H
adds a horizontal tab to the list of characters.

I
ignores case.

L
adds lowercase letters to the list of characters.

N
adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.

O
processes the *charlist* and *modifier* arguments only once, at the first call to this instance of COUNTC. If you change the value of *charlist* or *modifier* in subsequent calls, the change might be ignored by COUNTC.

P
adds punctuation marks to the list of characters.

Q
ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of *string* contains unmatched quotation marks, then scanning from left to right produces different words than scanning from right to left.

S
adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).

T
trims trailing blanks from *string* and *chars*. If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the COUNTC function with the T modifier.

U
adds uppercase letters to the list of characters.

V
counts characters that do not appear in the list of characters. If you do not specify this modifier, then COUNTC counts characters that do appear in the list of characters.

W
adds printable characters to the list of characters.

X
adds hexadecimal characters to the list of characters.

Data type CHAR, VARCHAR

Details

Definition of "Word"

In the COUNTW function, "word" refers to a substring that has one of the following characteristics:

- is bounded on the left by a delimiter or the beginning of the string
- is bounded on the right by a delimiter or the end of the string
- contains no delimiters, except if you use the Q modifier and the delimiters are within substrings that have quotation marks

Note: The definition of "word" is the same in both the SCAN function and the COUNTW function.

Delimiter refers to any of several characters that you can specify to separate words.

Using the COUNTW Function in an ASCII Environments

If you use the COUNTW function with only two arguments, here are the default delimiters.

- If your computer uses ASCII characters, then the default delimiters are as follows:

blank ! $ % & ( ) * + , - . / ; < ^ |

Using Null Arguments

The COUNTW function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.

Using the M Modifier

If you do not use the M modifier, then a word must contain at least one character. If you use the M modifier, then a word can have a length of zero. In this case, the number of words is one plus the number of delimiters in the string, not counting delimiters inside strings that are enclosed in quotation marks when you use the Q modifier.

Example

The following program shows how to use the COUNTW function with the M and P modifiers.

The explanation for the value of **mp** for each string is as follows:

- The period is the delimiter and the m modifier causes the period at the end to refer to a subsequent word with zero length, but still a word. So there is one word before the period and one word after the period for a total of two words.
- No delimiters, so there is only one word.
- The p modifier adds punctuation as a delimiter therefore 3 words.
- The p modifier adds punctuation, so / is a delimiter. The m modifier causes the leading / to refer to a word at beginning with zero length for a total of six words.
- The first \ is an escape character. The second \ is a delimiter, so there are six words.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(60) string1 having informat $char60. format $char60.;
   method init();
      string1='The quick brown fox jumps over the lazy dog.'; output;
      string1='        Leading blanks'; output;
      string1='2+2=4'; output;
      string1='/unix/path/names/use/slashes'; output;
      string1='\Windows\Path\Names\Use\Backslashes'; output;
   end;
enddata;
run;

data test_out (overwrite=yes);
```

```
   dcl double default blanks mp;
   method run();
      set test;
      default = countw(string1);
      blanks = countw(string1, ' ');
      mp = countw(string1, '.', 'mp');
      put 'String= ' string1 'Default= ' default 'Blanks= ' blanks
'MP= ' mp;
   end;
enddata;
run;
quit;
```

Output 7.7 *Results from Using the COUNTW Function with the M and P Modifiers*

default	blanks	mp	string1
9	9	2	The quick brown fox jumps over the lazy dog.
2	2	1	Leading blanks
2	1	3	2+2=4
5	1	6	/unix/path/names/use/slashes
1	1	6	\Windows\Path\Names\Use\Backslashes

Note: Double backslashes are used in the Windows pathname.

- “SCAN Function” on page 1123

CSC Function

Returns the cosecant.

Category:	Trigonometric
Returned data type:	DOUBLE

Syntax

CSC(*argument*)

Required Argument

argument
specifies a numeric constant, variable, or expression and is expressed in radians.

Restriction *argument* cannot be 0 or a multiple of PI.

Data type DOUBLE

Comparisons

The CSC function is related to the SIN function in this way:

```
csc(x)=1/sin(x)
```

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y z;
   method run();
      x=csc(.5);
      y=csc(1);
      z=csc(3.14159/3);
      put x;
      put y;
      put z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2.08582964293348
1.18839510577812
1.15470112806662
```

Note: If you use `x=csc(0);`, then the CSC function returns a missing value, and a note is written to the log that indicates you entered an invalid argument to the function. This is the correct behavior.

CSS Function

Returns the corrected sum of squares.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

CSS(*expression*[, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least one non-null or nonmissing expression is required.

Data type: DOUBLE

See: “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Example

The following program illustrates the CSS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3 x4;
```

```
      method run();
         x1=css(5,9,3,6);
         put x1=;
         x2=css(5,8,9,6,.);
         put x2=;
         x3=css(8,9,6,.);
         put x3=;
         x4=css(of x1-x3);
         put x4=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log.

```
x1=18.75
x2=10
x3=4.66666666666666
x4=101.11574074074
```

See Also

Functions:

- "USS Function" on page 1242

CUMIPMT Function

Returns the cumulative interest paid on a loan between the start and end period.

Category:	Financial
Returned data type:	DOUBLE

Syntax

CUMIPMT(*rate*, *number-of-periods*, *principal-amount*[, *start-period*][, *end-period*][, *type*])

Required Arguments

rate

specifies the interest rate per payment period.

Data type DOUBLE

number-of-periods
specifies the number of payment periods. *Number-of-periods* must be a positive, whole number.

Data type DOUBLE

principal-amount
specifies the principal amount of the loan. Zero is assumed if a missing value is specified.

Data type DOUBLE

Optional Arguments

start-period
specifies the start period for the calculation.

Data type DOUBLE

end-period
specifies the end period for the calculation.

Data type DOUBLE

type
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if *type* is omitted or if a missing value is specified.

Data type DOUBLE

Example

- The cumulative interest that is paid during the second year of a $125,000, 30-year loan with end-of-period monthly payments and a nominal annual interest rate of 9%, is computed as follows:

  Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
   dcl double TotalInterest having format dollar10.2;
   method run();
      TotalInterest= CUMIPMT(0.09/12, 360, 125000, 13, 24, 0);
      put 'Total Interest=' TotalInterest;
   end;
enddata;
run;
quit;
```

This computation returns a value of $11,135.23.

- The interest that is paid on the first period of the same loan is computed in the following way:

  Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
   dcl double first_period_interest having format dollar10.2;
   method run();
      first_period_interest= CUMIPMT(0.09/12, 360, 125000, 1, 1, 0);
      put 'Total Interest=' first_period_interest;
   end;

enddata;
run;
quit;
```

  This computation returns a value of $937.50.

See Also

Functions:

- “CUMPRINC Function” on page 492

CUMPRINC Function

Returns the cumulative principal paid on a loan between the start and end period.

Category: Financial

Returned data type: DOUBLE

Syntax

CUMPRINC(*rate*, *number-of-periods*, *principal-amount*[, *start-period*] [, *end-period*][, *type*])

Required Arguments

rate
specifies the interest rate per payment period.

Data type DOUBLE

number-of-periods
specifies the number of payment periods.

Requirement *Number-of-periods* must be a positive whole number.

Data type DOUBLE

principal-amount
specifies the principal amount of the loan.

Data type DOUBLE

Note Zero is assumed if a missing or null value is specified.

Optional Arguments

start-period
specifies the start period for the calculation.

Data type DOUBLE

end-period
specifies the end period for the calculation.

Data type DOUBLE

type
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if *type* is omitted or if a missing value is specified.

Data type DOUBLE

Example

- The cumulative principal that is paid during the second year of a $125,000, 30-year loan with end-of-period monthly payments and a nominal annual interest rate of 9%, is computed as follows:

  Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
   dcl double PrincipalYear2 having format dollar10.2;
   method run();
      PrincipalYear2=CUMPRINC(0.09/12, 360, 125000, 12, 24, 0);
      put 'Principal Year 2 EOP=' PrincipalYear2;
   end;
enddata;
run;
```

```
quit;
```

This computation returns a value of $1008.23.

- The principal that is paid on the second year of the same loan with beginning-of-period payments is computed as follows:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
   dcl double PrincipalYear2b having format dollar10.2;
   method run();
      PrincipalYear2b = CUMPRINC(0.09/12, 360, 125000, 12, 24, 1);
      put 'Principal Year 2 BOP=' PrincipalYear2b;
   end;
enddata;
run;
quit;
```

This computation returns a value of $1000.73.

CV Function

Returns the coefficient of variation.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

CV(*expression-1*, *expression-2* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement At least two arguments are required.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the CV function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3 x4;
   method run();
      x1=cv(5, 9, 3, 6);
      put x1=;
      x2=cv(5, 8, 9, 6, .);
      put x2=;
      x3=cv(8, 9, 6, .);
      put x3=;
      x4=cv(of x1-x3);
      put x4=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x1=43.4782608695652
x2=26.082026547865
x3=19.9242421519819
x4=40.9535392160926
```

DAIRY Function

Returns the derivative of the AIRY function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

DAIRY(*x*)

Required Argument

x
specifies a numeric constant, variable, or expression.

Details

The DAIRY function returns the value of the derivative of the AIRY function. (See a list of References.)

Example

The following program illustrates the DAIRY function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y;
   method run();
      x=dairy(2.0);
      put x;
      y=dairy(-2.0);
      put y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
-0.05309038443365
0.61825902074169
```

DATDIF Function

Returns the number of days between two dates after computing the difference between the dates according to specified day count conventions.

Category: Date and Time

Returned data type: DOUBLE

Syntax

DATDIF(*sdate*, *edate*, *basis*)

Required Arguments

sdate

specifies a SAS date value that identifies the starting date.

Data type DATE

Tip If *sdate* falls at the end of a month, then SAS treats the date as if it were the last day of a 30-day month.

edate

specifies a SAS date value that identifies the ending date.

Data type DATE

Tip If *edate* falls at the end of a month, then SAS treats the date as if it were the last day of a 30-day month.

basis

specifies a character string that represents the day count basis. The following values for *basis* are valid: '30/360', 'ACT/ACT', 'ACT/360', and 'ACT/365'. For example, 'ACT/365' uses the actual number of calendar days in a particular month, and 365 days as the number of days in a year, regardless of the actual number of days in a year. For more information, see *SAS DS2 Language Reference*.

specifies a character string that represents the day count basis. The following values for *basis* are valid:

'30/360'

specifies a 30-day month and a 360-day year, regardless of the actual number of calendar days in a month or year.

A security that pays interest on the last day of a month either always makes its interest payments on the last day of the month, or it always makes its payments on the numerically same day of a month. The only exception is when that day is not a valid day of the month, such as February 30. For more information, see "Method of Calculation for Day Count Basis (30/360)" in *SAS Functions and CALL Routines: Reference*.

Alias '360'

'ACT/ACT'

uses the actual number of days between dates. Each month is considered to have the actual number of calendar days in that month, and each year is considered to have the actual number of calendar days in that year.

Alias *'Actual'*

'ACT/360'
uses the actual number of calendar days in a particular month, and 360 days as the number of days in a year, regardless of the actual number of days in a year.

Tip *ACT/360* is used for short-term securities.

'ACT/365'
uses the actual number of calendar days in a particular month, and 365 days as the number of days in a year, regardless of the actual number of days in a year.

Tip *ACT/365* is used for short-term securities.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

The Basics

The DATDIF function has a specific meaning in the securities industry, and the method of calculation is not the same as the actual day count method. Calculations can use months and years that contain the actual number of days. Calculations can also be based on a 30-day month or a 360-day year. For more information about standard securities calculation methods, see the References section at the bottom of this function.

Note: When counting the number of days in a month, DATDIF *always* includes the starting date and excludes the ending date.

Method of Calculation for Day Count Basis (30/360)

To calculate the number of days between two dates, use the following formula:

$$Number of days = [(Y2 - Y1) * 360] + [(M2 - M1) * 30] + (D2 - D1)$$

Arguments

Y2
specifies the year of the later date.

Y1
specifies the year of the earlier date.

M2
specifies the month of the later date.

M1
specifies the month of the earlier date.

D2
specifies the day of the later date.

D1
specifies the day of the earlier date.

Because all months can contain only 30 days, you must adjust for the months that do not contain 30 days. Do this before you calculate the number of days between the two dates.

The following rules apply:

- If the security follows the End-of-Month rule, and D2 is the last day of February (28 days in a non-leap year, 29 days in a leap year), and D1 is the last day of February, then change D2 to 30.
- If the security follows the End-of-Month rule, and D1 is the last day of February, then change D1 to 30.
- If the value of D2 is 31 and the value of D1 is 30 or 31, then change D2 to 30.
- If the value of D1 is 31, then change D1 to 30.

Example

In the following program, DATDIF returns the actual number of days between two dates, as well as the number of days based on a 30-day month and a 360-day year.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl date sdate edate;
   dcl double actual days360;
   method run();
      sdate= date'1978-10-16';
      edate= date'1996-02-16';
      sassdate=to_double(sdate);
      sasedate=to_double(edate);
      actual=datdif(sassdate, sasedate, 'act/act');
      days360=datdif(sassdate, sasedate, '30/360');
      put  'Actual= ' actual;
      put 'Days 360 = ' days360;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
Actual= 6332
Days 360= 6240
```

DATE Function

Returns the current date as a SAS date value.

Category:	Date and Time
Alias:	TODAY
Returned data type:	DOUBLE

Syntax

DATE( )

Without Arguments

The DATE function has no arguments.

Comparisons

The DATE function does not take any arguments. The SAS date value returned is the number of days from January 1, 1960 to the current date.

For more information about how DS2 handles dates, see “DS2 Expressions” in *SAS DS2 Programmer’s Guide*.

Example

The following program illustrates the DATE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x having format nldate.;
   method run();
      x=date();
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
January 22, 2019
```

Functions:

- "TODAY Function" on page 1218

DATEJUL Function

Converts a Julian date to a SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

DATEJUL(*julian-date*)

Required Argument

julian-date
specifies any valid expression that evaluates to a numeric value and that represents a Julian date. A Julian date is a date in the form *yyddd* or *yyyyddd*, where *yy* or *yyyy* is a two-digit or four-digit whole number that represents the year and *ddd* is the number of the day of the year. The value of *ddd* must be between 1 and 365 (or 366 for a leap year).

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

A SAS date value is the number of days from January 1, 1960 to a specified date. The DATEJUL function returns the number of days from January 1, 1960 to the Julian date specified in *julian-date*.

For more information about how dates are handled in DS2, see "DS2 Expressions" in *SAS DS2 Programmer's Guide* .

Example

The following program illustrates the DATEJUL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double xstart xend having format nldate.;
   method run();
      xstart=datejul(94365);
      put xstart;
      xend=datejul(2001001);
      put xend;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
December 31, 1994
January 01, 2001
```

DATEPART Function

Extracts the date from a SAS datetime value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

DATEPART(*datetime*)

Required Argument

datetime
specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

A SAS datetime value is the number of seconds between January 1, 1960 and the hour, minute, and seconds within a specific date. The DATEPART function determines the date portion of the SAS datetime value and returns the date as a SAS date value, which is the number of days from January 1, 1960.

Example

The following program illustrates the DATEPART function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double dtvalue;
   dcl double dp having format date9.;
   method run();
      dtvalue=1652165417;
      dp=datepart(dtvalue);
      put dp;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
09MAY2012
```

See Also

- "TIMEPART Function" on page 1202

DATETIME Function

Returns the current date and time of day as a SAS datetime value.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

DATETIME( )

Comparisons

The DATETIME function does not take any arguments. The SAS datetime value returned is the number of seconds from January 1, 1960 to the current date and time.

Example

The following program illustrates the DATETIME function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double dt ;
   method run();
      dt=datetime();
      put dt;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1865079581.31599
```

See Also

Concepts:

- "Dates and Times in DS2" in *SAS DS2 Programmer's Guide*

Functions:

- "DATE Function" on page 500
- "TIME Function" on page 1200

DAY Function

Returns the day of the month from a SAS date value.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

DAY(*date*)

Required Argument

date
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The DAY function produces a whole number from 1 to 31 that represents the day of the month.

A SAS date value is the number of days from January 1, 1960 to a specific date.

Example

The following program illustrates the DAY function where `dayvalue`, the SAS date value, has a value of 22541, which is the 18th day of the month:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double dv;
   method run();
      dv=day(22541);
      put dv;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
18
```

DEQUOTE Function

Removes matching single quotation marks from a character string that begins with a single quotation mark, and deletes all characters to the right of the closing quotation mark.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

DEQUOTE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The value that is returned by the DEQUOTE function depends on the first character or the first two characters in *expression*:

- If the first character of *expression* is not a quotation mark, DEQUOTE returns a syntax error.
- If the first character of *expression* is a single quotation mark, the DEQUOTE function removes that single quotation mark from the result. DEQUOTE then scans *expression* from left to right, looking for more single quotation marks or double quotation marks.

  All paired single quotation marks are replaced with a single quotation mark.

  All paired double quotation marks are retained.

  If a double quotation mark is the second character, DEQUOTE removes the double quotation mark from the result. DEQUOTE then scans *expression* from left to right. If a matching double quotation mark is found, the text between the double quotation marks is returned. Any text to the right of the closing double quotation mark, to the end of *expression* is removed from the result.

The first non-paired single quotation mark in *expression* is the closing single quotation mark and is removed.

If a close parenthesis follows the close single quotation mark, the function returns the dequoted string. If characters exist to the right of the close single quotation mark, the function results in a syntax error and the error is printed in the SAS log.

- If *expression* is enclosed in double quotation marks, the DEQUOTE function returns a null or missing value.

Note: If *expression* is a constant enclosed in quotation marks, those quotation marks are not part of the value of *expression*. Therefore, you do not need to use DEQUOTE to remove the quotation marks that denote a constant.

Examples

Example 1: No Quotation Marks

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
   method run();
      string= dequote(Omitting quotation marks causes an error);
      put string;
   end;
enddata;
run;
quit;
```

SAS writes the following errors to the log.

```
ERROR: Compilation error.
ERROR: Line 8: Parse encountered identifier when expecting ')'.
ERROR: Line 8: Parse failed:  string= dequote(Omitting  >>> quotation <<<  marks causes an error
```

Example 2: No Leading Quotation Marks in the String

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
```

```
   method run();
      string= dequote(No 'leading' quotation marks cause an error);
      put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
ERROR: Compilation error.
ERROR: Line 28: Parse encountered constant when expecting ')'.
ERROR: Line 28: Parse failed:  string= dequote(No  >>> 'leading' <<<  quotation marks caus
```

Example 3: Single Matched Quotation Marks

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
   method run();
      string = dequote(' "Single matched quotation marks are removed"
');
      put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
"Single matched quotation marks are removed"
```

Example 4: Matched Double Quotation Marks

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
   method run();
      string= dequote("Matched double quotation marks cause an
error.");
      put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
ERROR: Compilation error.
WARNING: Line 68: No DECLARE for referenced variable "matched double quotation marks cause an
error."; creating it as a global variable of type double.
ERROR: BASE driver, Column name Matched double quotation marks cause an error. is too long for a
 SAS name
ERROR: Unable to execute CREATE TABLE statement for table work.test.
```

Example 5: Paired Single Quotation Marks

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
   method run();
       string= dequote('Paired '' single '' quotation marks are
reduced to a
          single quotation mark');
       put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
Paired ' single ' quotation marks are reduced to a single quotation mark
```

Example 6: Double Quotation Marks within Single Quotation Marks with a Space Before the Open Quotation Mark

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(100) string;
   method run();
       string= dequote(' "Double quotation marks within single
quotation marks,
          with space before open quotation mark" ');
       put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
"Double quotation marks within single quotation marks, with space before open quotation mark"
```

Example 7: Double Quotation Marks within Single Quotation Marks Without a Space Before the Open Quotation Mark

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(110) string;
   method run();
       string= dequote(dequote('"Double quotation marks within single
quotation
          marks, without space before open quotation mark causes an
error"'););
       put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
ERROR: Compilation error.
ERROR: Line 103: Parse encountered ';' when expecting ')'.
ERROR: Line 103: Parse failed: ) >>> ; <<< );
```

Example 8: Test after Closing Double Quotation Mark

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
   method run();
       string= dequote(' "Text after closing double quotation mark"
          is removed ');
       put string;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
"Text after closing double quotation mark" is removed
```

Example 9: No Matching Quotation Mark

The following program illustrates the DEQUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(75) string;
   method run();
        string= dequote(' No matching quotation mark);
        put string;
   end;
enddata;
run;
quit;
```

The request stops responding, searching for the closing quotation mark. Examine your code closely for unbalanced quotations before submitting it.

DEVIANCE Function

Returns the deviance based on a probability distribution.

Category: Mathematical

Returned data type: DOUBLE

Syntax

DEVIANCE(*distribution*, *variable*, *shape-parameter(s)*[, *ε*])

Required Arguments

distribution

is a character constant, variable, or expression that identifies the distribution. Valid distributions are 'BERNOULLI', 'BINOMIAL', 'GAMMA', 'IGAUSS', 'NORMAL', and 'POISSON'. See *SAS DS2 Language Reference* for descriptions of the parameters supported for each of these distributions.

is a character constant, variable, or expression that identifies the distribution. Valid distributions are listed in the following table:

Distribution	Argument
Bernoulli (p. 513)	'BERNOULLI' | 'BERN'

Distribution	Argument
Binomial (p. 514)	'BINOMIAL' | 'BINO'
Gamma (p. 514)	'GAMMA'
Inverse Gauss (Wald) (p. 515)	'IGAUSS' | 'WALD'
Normal (p. 515)	'NORMAL' | 'GAUSSIAN'
Poisson (p. 516)	'POISSON' | 'POIS'

variable
is a numeric constant, variable, or expression.

shape-parameter(s)
are one or more distribution-specific numeric parameters that characterize the shape of the distribution.

Optional Argument

ε
is an optional numeric small value used for all of the distributions, except for the normal distribution.

Details

The Bernoulli Distribution

DEVIANCE('BERNOULLI', *variable*, *p*[, *ε*])

Arguments

variable
is a binary numeric random variable that has the value of 1 for success and 0 for failure.

p
is a numeric probability of success with $\varepsilon \le p \le 1-\varepsilon$.

ε
is an optional positive numeric value that is used to bound *p*. Any value of *p* in the interval $0 \le p \le \varepsilon$ is replaced by *ε*. Any value of *p* in the interval $1 - \varepsilon \le p \le 1$ is replaced by $1 - \varepsilon$.

The DEVIANCE function returns the deviance from a Bernoulli distribution with a probability of success *p*, where success is defined as a random variable value of 1. The equation follows:

$$\text{DEVIANCE}('BERN', variable, p, \varepsilon) = \begin{cases} -2\log(1-p) & x = 0 \\ -2\log(p) & x = 1 \\ . & otherwise \end{cases}$$

The Binomial Distribution

DEVIANCE('BINO', *variable*, *μ*, *n*[, *ε*])

Arguments

variable
is a numeric random variable that contains the number of successes.

Range 0 ≤ *variable* ≤ 1

μ
is a numeric mean parameter.

Range $n\varepsilon \le \mu \le n(1-\varepsilon)$

n
is a whole number of Bernoulli trials parameter

Range $n \ge 0$

ε
is an optional positive numeric value that is used to bound *μ*. Any value of *μ* in the interval $0 \le \mu \le n\varepsilon$ is replaced by *nε*. Any value of *μ* in the interval $n(1-\varepsilon) \le \mu \le n$ is replaced by $n(1-\varepsilon)$.

The DEVIANCE function returns the deviance from a binomial distribution, with a probability of success *p*, and a number of independent Bernoulli trials *n*. The following equation describes the DEVIANCE function for the Binomial distribution, where *x* is the random variable:

$$\text{DEVIANCE}('BINO', x, \mu, n) = \begin{cases} . & x < 0 \\ 2\left(x\log\left(\frac{x}{\mu}\right) + (n-x)\log\left(\frac{n-x}{n-\mu}\right)\right) & 0 \le x \le n \\ . & x > n \end{cases}$$

The Gamma Distribution

DEVIANCE('GAMMA', *variable*, *μ*[, *ε*])

Arguments

variable
is a numeric random variable.

Range *variable* ≥ *ε*

μ
is a numeric mean parameter.

Range $\mu \ge \varepsilon$

ε
is an optional positive numeric value that is used to bound *variable* and *μ*. Any value of *variable* in the interval $0 \le variable \le \varepsilon$ is replaced by *ε*. Any value of *μ* in the interval $0 \le \mu \le \varepsilon$ is replaced by *ε*.

The DEVIANCE function returns the deviance from a gamma distribution with a mean parameter μ. The following equation describes the DEVIANCE function for the gamma distribution, where x is the random variable:

$$\text{DEVIANCE}('GAMMA', x, \mu) = \begin{cases} . & x < 0 \\ 2\left(-\log\left(\frac{x}{\mu}\right) + \frac{x-\mu}{\mu}\right) & x \geq \varepsilon, \mu \geq \varepsilon \end{cases}$$

The Inverse Gauss (Wald) Distribution

DEVIANCE('IGAUSS' | 'WALD', *variable*, μ[, ε])

Arguments

variable
is a numeric random variable.

Range *variable* ≥ ε

μ
is a numeric mean parameter.

Range $\mu \geq \varepsilon$

ε
is an optional positive numeric value that is used to bound *variable* and μ. Any value of *variable* in the interval 0 ≤ *variable* ≤ ε is replaced by ε. Any value of μ in the interval 0 ≤ μ ≤ ε is replaced by ε.

The DEVIANCE function returns the deviance from an inverse Gaussian distribution with a mean parameter μ. The following equation describes the DEVIANCE function for the inverse Gaussian distribution, where x is the random variable:

$$\text{DEVIANCE}('IGAUSS', x, \mu) = \begin{cases} . & x < 0 \\ \frac{(x-\mu)^2}{\mu^2 x} & x \geq \varepsilon, \mu \geq \varepsilon \end{cases}$$

The Normal Distribution

DEVIANCE('NORMAL' | 'GAUSSIAN', *variable*, μ)

Arguments

variable
is a numeric random variable.

μ
is a numeric mean parameter.

The DEVIANCE function returns the deviance from a normal distribution with a mean parameter μ. The following equation describes the DEVIANCE function for the normal distribution, where x is the random variable:

$$\text{DEVIANCE}('NORMAL', x, \mu) = (x-\mu)^2$$

The Poisson Distribution

DEVIANCE('POISSON', *variable*, μ[, ε])

Arguments

variable
is a numeric random variable.

Range *variable* ≥ 0

μ
is a numeric mean parameter.

Range $\mu \geq \varepsilon$

ε
is an optional positive numeric value that is used to bound μ. Any value of μ in the interval $0 \leq \mu \leq \varepsilon$ is replaced by ε.

The DEVIANCE function returns the deviance from a Poisson distribution with a mean parameter μ. The following equation describes the DEVIANCE function for the Poisson distribution, where x is the random variable:

$$\text{DEVIANCE}('POISSON', x, \mu) = \begin{cases} . & x < 0 \\ 2\left(x\log\left(\frac{x}{\mu}\right) - (x - \mu)\right) & x \geq 0, \mu \geq \varepsilon \end{cases}$$

DHMS Function

Returns a SAS datetime value from date, hour, minute, and second values.

Category: Date and Time

Returned data type: DOUBLE

Syntax

DHMS(*date*, *hour*, *minute*, *second*)

Required Arguments

date
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

hour
specifies a numeric expression that represents a whole number from 1 through 12.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

minute
specifies a numeric expression that represents a whole number from 1 through 59.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

second
specifies a numeric expression that represents a whole number from 1 through 59.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The DHMS function returns a numeric value that represents a SAS datetime value. This numeric value can be either positive or negative.

Examples

Example 1: Using the DHMS Function

The following program illustrates the DHMS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double dtvalue;
   method run();
      dtvalue=dhms(mdy(12,31,2018),12,01,01);
      put dtvalue;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1861876861
```

Example 2: Combining Date and Time Values

The following program illustrates how to combine a SAS date value with a SAS time value into a SAS datetime value, using the current day and time.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double day tme dt;
   method run();
      day=date();
      tme=time();
      dt=dhms(day,0,0,tme);
      put dt;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1863788289.77899
```

Example 3: Using Datetime Values

The following program illustrates how to use the DHMS function with datetime values.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double dtid dtid1 dtid2 having format datetime.;
   method run();
      dtid=dhms(mdy(01, 03, 2018), 15, 30, 15);
      put dtid;
      dtid1=dhms(mdy(01, 03, 2018), 15, 30, 61);
      put dtid1;
      dtid2=dhms(mdy(01, 03, 2018), 15, .5, 15);
      put dtid2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
03JAN18:15:30:15
03JAN18:15:31:01
03JAN18:15:00:45
```

See Also

Concepts:

- "Dates and Times in DS2" in *SAS DS2 Programmer's Guide*

Functions:

- "HMS Function" on page 700

DIF Function

Returns differences between an argument and its *n*th lag.

Category: Special

Returned data type: Same as the expression's data type

Syntax

DIF[*n*] (*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type BIGINT, DECIMAL, DOUBLE, INTEGER, TINYINT

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

n
specifies the number of lags.

Range 1 to 100

Data type INTEGER

Details

The DIF functions, DIF1, DIF2, ..., DIF*n*, return the differences between the expression value and its *n*th lag. DIF1 can also be written as DIF. DIF*n* is defined as DIF*n*(*x*)=*x*-LAG*n*(*x*).

Note: To avoid unexpected behavior with data underflow or overflow, if expression is a SMALLINT or a TINYINT, DS2 converts expression to INTEGER before processing the DIF function. After processing, DS2 converts expression back to SMALLINT and TINYINT and handle the underflow or overflow in the same way it is done for all other processing.

For details about storing and returning values from the LAG*n* queue, see the LAG function.

Comparisons

The function DIF2(X) is not equivalent to the difference DIF(DIF(X)).

Examples

Example 1

The following program illustrates the difference between the LAG and DIF functions.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data one (overwrite=yes);
    declare int x z d;
    method run();
       do x=1,2,6,4,7;
          z=lag(x);
          d=dif(x);
          output;
       end;
    end;
enddata;
run;
quit;

proc print data=one;
run;
```

Output 7.8 *Difference between the DIF and LAG Functions*

Obs	x	z	d
1	1	.	.
2	2	1	1
3	6	2	4
4	4	6	-2
5	7	4	3

Example 2: Using Expressions as Arguments

The following program illustrates how string expressions are converted to doubles.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(8) i difi;
   method init();
      do i=' 2', '  4', '   6', '10  ', 'abc';
         difi=dif(i);
         put i= difi=;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
i= 2       difi=.
i=  4      difi=2
i=   6     difi=2
i=10       difi=4
i=abc      difi=.
```

- "LAG Function" on page 804

DIGAMMA Function

Returns the value of the digamma function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

DIGAMMA(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Restriction: Zero and negative integers are not valid.

Data type: DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The DIGAMMA function returns the ratio that is given by the following equation.

$$\Psi(x) = \Gamma'(x)/\Gamma(x)$$

$\Gamma(.)$ and $\Gamma'(.)$ denote the gamma function and its derivative, respectively. For *expression*>0, the DIGAMMA function is the derivative of the lgamma function.

Example

The following program illustrates the DIGAMMA function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
```

```
        x=digamma(1.0);
        put x;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
-0.57721566490153
```

DIM Function

Returns the number of elements in an array.

Category: Array

Returned data type: INTEGER

Syntax

DIM(*array-name*[, *bound-n*])

Required Argument

array-name
specifies the name of a temporary or a variable array.

Optional Argument

bound-n
is a numeric constant, variable, or expression that specifies the dimension, in a multidimensional array, for which you want to know the number of elements. If no *bound-n* value is specified, the DIM function returns the number of elements in the first dimension of the array.

Bound-n evaluates to an integral value.

Data type INTEGER

Details

The DIM function returns the number of elements in a one-dimensional array, or the number of elements in a specified dimension of a multidimensional array.

If the DIM function is called with a *bound-n* dimension value that is outside the dimension of the array, then a run-time error occurs and the function returns a NULL integer value.

Comparisons

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
- LBOUND returns the value of the lower bound of an array dimension.
- NDIMS returns the number of dimensions in an array.

Example

The following program shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;

   method init();
      declare char(15) a1[4];
      declare double   a2[2,3,4] sum;

      a1 := ('red' 'yellow' 'green' 'blue');
      a2 := (24*2.0);

      do i = 1 to dim(a1);
         put a1[i];
      end;

      numelems = 0;
      do i = 1 to ndims(a2);
         numelems = numelems + dim(a2, i);
      end;

      sum = 0;

      do i = lbound(a2, 1) to hbound(a2, 1);
        do j = lbound(a2, 2) to hbound(a2, 2);
          do k = lbound(a2, 3) to hbound(a2, 3);
             sum = sum + a2[i,j,k];
          end;
        end;
      end;

      put sum=;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
red
yellow
green
blue
sum=48
```

DIVIDE Function

Returns the result of a division that handles special missing values for ODS output.

Category: Arithmetic

Returned data type: DOUBLE

Syntax

DIVIDE(*x*, *y*)

Required Arguments

x

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

y

specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The DIVIDE function divides two numbers and returns a result that is compatible with ODS conventions. The function handles special missing values for ODS output. The following list shows how certain special missing values are interpreted in ODS:

- .I as infinity
- .M as minus infinity
- ._ as a blank

The following table shows the values that are returned by the DIVIDE function, based on the values of *x* and *y*.

Figure 7.1 *Values That Are Returned by the DIVIDE Function*

		x						
		positive	zero	negative	.I	.M	._	other
y	positive	x/y or .I	0	x/y or .M	.I	.M	._	x
	zero	.I	.	.M	.I	.M	._	x
	negative	x/y or .M	0	x/y or .I	.M	.I	._	x
	.I	0	0	0	.	.	._	x
	.M	0	0	0	.	.	._	x
	._	._	._	._	._	._	._	._
	other	y	y	y	y	y	._	x

Note: The DIVIDE function never writes a note to the SAS log regarding missing values, division by zero, or overflow.

Example

The following program shows the results of using the DIVIDE function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c d;
   method run();
      a=divide(1, 0);
      put a='(infinity)';
      b=divide(2, .I);
```

```
        put b=;
        c=divide(.I, -1);
        put c='(minus infinity)';
        d=divide(constant('big'), constant('small'));
        put d='(infinity because of overflow)';
    end;
enddata;
run;
quit;
```

The following lines are written to the SAS log:

```
a=I (infinity)
b=0
c=M (minus infinity)
d=I (infinity because of overflow)
```

DUR Function

Returns the modified duration for an enumerated cash flow.

Category: Financial

Returned data type: DOUBLE

Syntax

DUR(*y*, *f*, *c(1), ..., c(k)*)

Required Arguments

y

specifies the effective per-period yield-to-maturity, expressed as a fraction.

Range $y > 0$

Data type DOUBLE

f

specifies the frequency of cash flows per period.

Range $f > 0$

Data type DOUBLE

c(1), ... ,c(k)

specifies a list of cash flows.

Data type DOUBLE

Details

The DUR function returns the value from the following equation.

$$C = \sum_{k=1}^{K} \frac{k\left(\frac{c(k)}{(1+y)^{\frac{k}{f}}}\right)}{(P(1+y)f)}$$

The following relationship applies to the preceding equation:

$$P = \sum_{k=1}^{K} \frac{c(k)}{(1+y)^{\frac{k}{f}}}$$

Example: Using the DUR Function

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double d;
   method run();
      d=dur(.05,1,.33,.44,.55,.49,.50,.22,.4,.8,.01,.36,.2,.4);
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
5.28402498798216
```

See Also

Functions:

- “DURP Function” on page 528

DURP Function

Returns the modified duration for a periodic cash flow stream, such as a bond.

Category: Financial

Returned data type: DOUBLE

Syntax

DURP(*A*, *c*, *n*, *K*, k_0, *y*)

Required Arguments

A

specifies the par value.

Range $A > 0$

Data type DOUBLE

c

specifies the nominal per-period coupon rate, expressed as a fraction.

Range $0 \le c < 1$

Data type DOUBLE

n

specifies the number of coupons per period.

Range $n > 0$ and is a whole number

Data type DOUBLE

K

specifies the number of remaining coupons.

Range $K > 0$ and is a whole number

Data type DOUBLE

k_o

specifies the time from the present date to the first coupon date, expressed in terms of the number of periods.

Range $0 < k_0 \le 1/n$

Data type DOUBLE

y

specifies the nominal per-period yield-to-maturity, expressed as a fraction.

Range $y > 0$

Data type DOUBLE

Details

The DURP function returns the value from the following equation.

$$D = \frac{1}{n}\frac{\sum_{k=1}^{K} t_k \frac{c(k)}{\left(1+\frac{y}{n}\right)^{t_k}}}{P\left(1+\frac{y}{n}\right)}$$

The following relationships apply to the preceding equation:

- $t_k = nk_0 + k - 1$
- $c(k) = \frac{c}{n}A \quad for\ k = 1, \ldots, K-1$
- $c(K) = \left(1+\frac{c}{n}\right)A$

The following relationship applies to the preceding equation:

$$P = \sum_{k=1}^{K} \frac{c(k)}{\left(1+\frac{y}{n}\right)^{t_k}}$$

Example: Using the DURP Function

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double d;
   method run();
      d=durp(1000,1/100,4,14,.33/2,.10);
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
3.33170731707317
```

Functions:

- “DUR Function” on page 527

EFFRATE Function

Returns the effective annual interest rate.

Category: Financial

Returned data type: DOUBLE

Syntax

EFFRATE(*compounding-interval*, *rate*)

Required Arguments

compounding-interval
is a SAS interval. This value represents how often *rate* compounds.

Data type CHAR

rate
is numeric. *Rate* is a nominal annual interest rate (expressed as a percentage) that is compounded at each compounding interval.

Data type DOUBLE

Details

The EFFRATE function returns the effective annual interest rate. The function computes the effective annual interest rate that corresponds to a nominal annual interest rate.

The following details apply to the EFFRATE function:

- The values for rates must be at least –99.
- In considering a nominal interest rate and a compounding interval, if *compounding-interval* is 'CONTINUOUS', then the value that is returned by EFFRATE equals $e^{rate/100}-1$.

  If *compounding-interval* is not 'CONTINUOUS', and *m* compounding intervals occur in a year, the value that is returned by EFFRATE equals $(1+[rate/100\ m])^{m-1}$.
- The following values are valid for *compounding-interval*:
  - 'CONTINUOUS'
  - 'DAY'

- 'SEMIMONTH'
- 'MONTH'
- 'QUARTER'
- 'SEMIYEAR'
- 'YEAR'

- If the interval is 'DAY', then *m*=365.

Example

The following programs show how the effective rate is calculated:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

- If a nominal rate is 10%, this program shows the corresponding effective rate when interest is compounded monthly.

```
proc ds2;
data test(overwrite=yes);
   dcl double effectiverate1;
   method run();
      effectiverate1=effrate('month', 10);
      put effectiverate1;
   end;
enddata;
run;
quit;
```

  The effective rate is 10.4713067441296.

- If a nominal rate is 10%, this program shows the corresponding effective rate when interest is compounded quarterly.

```
proc ds2;
data test(overwrite=yes);
   dcl double effectiverate1;
   method run();
      effectiverate1=effrate('quarter', 10);
      put effectiverate1;
   end;
enddata;
run;
quit;
```

  The effective rate is 10.3812890624999.

ERF Function

Returns the value of the (normal) error function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

ERF(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ERF function returns the integral, given by the following:

$$\mathrm{ERF}(x) = \frac{2}{\sqrt{\pi}} \int_0^x \varepsilon^{-z^2} dz$$

You can use the ERF function to find the probability (p) that a normally distributed random variable with mean 0 and standard deviation takes on a value less than X. For example, the quantity that is given by the following statement is equivalent to PROBNORM(X):

```
p=.5+.5*erf(x/sqrt(2));
```

Example

The following program illustrates the ERF function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y;
   method run();
      x=erf(1);
      y=erf(-1);
      put x=;
      put y=;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=0.84270079294971
y=-0.84270079294971
```

See Also

Functions:

- “ERFC Function” on page 534
- “PROBNORM Function” on page 1023

ERFC Function

Returns the value of the complementary (normal) error function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

ERFC(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The ERFC function returns the complement to the ERF function (that is, 1 – ERF(*argument*)).

Example

The following program illustrates the ERFC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y;
   method run();
      x=erfc(1);
      y=erfc(-1);
      put x=;
      put y=;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=0.15729920705028
y=1.84270079294971
```

See Also

Functions:

- "ERF Function" on page 532

EXP Function

Returns the value of the e constant raised to a specified power.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

EXP(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The EXP function raises the constant **e** to the power that is supplied by the argument. **e** is approximately given by 2.71828. The result is limited by the maximum value of a double decimal value on the computer.

Examples

Example 1: Using the EXP Function

The following program illustrates the EXP function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y;
   method run();
      x=exp(1.0);
      y=exp(0);
      put x=;
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=2.71828182845904
y=1
```

Example 2: Filling a Matrix Package Array

The following program creates two matrix packages and fills them with values of the EXP function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a[3, 3];
   dcl double c[3, 3];

   method run();
      dcl package matrix m;
      dcl package matrix r;
      dcl double i j;

      a := (1, 2, 3, 1, 2, 3, 1, 2, 3);

      m=_new_ matrix(a, 3, 3);
      r=m.exp();
      r.toarray(c);

      do i=1 to 3;
         do j=1 to 3;
            put c[i, j];
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2.71828182845904
7.38905609893065
20.0855369231876
2.71828182845904
7.38905609893065
20.0855369231876
2.71828182845904
7.38905609893065
20.0855369231876
```

FACT Function

Computes a factorial.

Category: Mathematical

Returned data type: DOUBLE

Syntax

FACT(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The mathematical representation of the FACT function is given by the following equation:

$$FACT(n) = n!$$

In this equation, $n \geq 0$.

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the FACT function.

Example

The following program illustrates the FACT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data;
  dcl double x y z;
  method run();
      x=fact(5);
      /* negative #s don't work */
      y=fact(-27);
      /* decimal #s do not work */
      z=fact(7.3);
      put x=;
      put y=;
      put z=;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=120
y=.
z=.
ERROR: Line 170: Invalid argument to function fact.
ERROR: Line 172: Invalid argument to function fact.
```

FINANCE Function

Computes financial calculations such as depreciation, maturation, accrued interest, net present value, periodic savings, and internal rates of return.

Category: Financial

Syntax

FINANCE(*string-identifier*, *parameter–1*, *parameter–2*, ...)

Required Arguments

string-identifier
specifies a character constant, variable, or expression. Valid values for *string-identifier* are listed in the following table.

string-identifier	**Description**
'ACCRINT'	computes the accrued interest for a security that pays periodic interest.
'ACCRINTM'	computes the accrued interest for a security that pays interest at maturity.
' AMORDEGRC'	computes the depreciation for each accounting period by using a depreciation coefficient.
'AMORLINC'	computes the depreciation for each accounting period.
'COUPDAYBS'	computes the number of days from the beginning of the coupon period to the settlement date.
'COUPDAYS'	computes the number of days in the coupon period that contains the settlement date.
'COUPDAYSNC'	computes the number of days from the settlement date to the next coupon date.

string-identifier	Description
'COUPNCD'	computes the next coupon date after the settlement date.
'COUPNUM'	computes the number of coupons that are payable between the settlement date and the maturity date.
'COUPPCD'	computes the previous coupon date before the settlement date.
'CUMIPMT'	computes the cumulative interest that is paid between two periods.
'CUMPRINC'	computes the cumulative principal that is paid on a loan between two periods.
'DB'	computes the depreciation of an asset for a specified period by using the fixed-declining balance method.
'DDB'	computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.
'DISC'	computes the discount rate for a security.
'DOLLARDE'	converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.
'DOLLARFR'	converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.
'DURATION'	computes the annual duration of a security with periodic interest payments.
'EFFECT'	computes the effective annual interest rate.
'FV'	computes the future value of an investment.
'FVSCHEDULE'	computes the future value of an initial principal after applying a series of compound interest rates.
'INTRATE'	computes the interest rate for a fully invested security.
'IPMT'	computes the interest payment for an investment for a given period.
'IRR'	computes the internal rate of return for a series of cash flows.

string-identifier	Description
'ISPMT'	calculates the interest paid during a specific period of an investment.
'MDURATION'	computes the Macaulay modified duration for a security with an assumed face value of $100.
'MIRR'	computes the internal rate of return where positive and negative cash flows are financed at different rates.
'NOMINAL'	computes the annual nominal interest rate.
'NPER'	computes the number of periods for an investment.
'NPV'	computes the net present value of an investment based on a series of periodic cash flows and a discount rate.
'ODDFPRICE'	computes the price per $100 face value of a security with an odd first period.
'ODDFYIELD'	computes the yield of a security with an odd first period.
'ODDLPRICE'	computes the price per $100 face value of a security with an odd last period.
'ODDLYIELD'	computes the yield of a security with an odd last period.
'PMT'	computes the periodic payment for an annuity.
'PPMT'	computes the payment on the principal for an investment for a given period.
'PRICE'	computes the price per $100 face value of a security that pays periodic interest.
'PRICEDISC'	computes the price per $100 face value of a discounted security.
'PRICEMAT'	computes the price per $100 face value of a security that pays interest at maturity.
'PV'	computes the present value of an investment.
'RATE'	computes the interest rate per period of an annuity.

string-identifier	Description
'RECEIVED'	computes the amount received at maturity for a fully invested security.
'SLN'	computes the straight-line depreciation of an asset for one period.
'SYD'	computes the sum-of-years digits depreciation of an asset for a specified period.
'TBILLEQ'	computes the bond-equivalent yield for a treasury bill.
'TBILLPRICE'	computes the price per $100 face value for a treasury bill.
'TBILLYIELD'	computes the yield for a treasury bill.
'VDB'	computes the depreciation of an asset for a specified or partial period by using a declining balance method.
'XIRR'	computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.
'XNPV'	computes the net present value for a schedule of cash flows that is not necessarily periodic.
'YIELD'	computes the yield on a security that pays periodic interest.
'YIELDDISC'	computes the annual yield for a discounted security (for example, a treasury bill).
'YIELDMAT'	computes the annual yield of a security that pays interest at maturity.

parameter
specifies a parameter that is associated with each *string-identifier*.

The following parameters are available:

basis
is an optional parameter that specifies a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360

Numeric Value	String Value	Day Count Method
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

interest-rates
specifies rates that are provided as numeric values and not as percentages.

dates
specifies that all dates in the financial functions are SAS dates.

sign-of-cash-values
for all the arguments, specifies that the cash that you pay out, such as deposits to savings or other withdrawals, is represented by negative numbers. It also specifies that the cash that you receive, such as dividend checks and other deposits, is represented by positive numbers.

FINANCE ACCRINT Function

Computes the accrued interest for a security that pays periodic interest.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('ACCRINT', *issue*, *first-interest*, *settlement*, *rate*, *par-value*, *frequency*, [*basis*]);

Required Arguments

issue
specifies the issue date of the security.

Requirement *Issue* is a SAS date.

Data type DOUBLE

first-interest
specifies the first interest date of the security.

Requirement *First-interest* is a SAS date.

Data type DOUBLE

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

par-value
specifies the par value of the security. If you omit *par-value*, SAS uses the value `$1000`.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Accrued Interest: ACCRINT

The following program computes the accrued interest for a security that pays periodic interest.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double issue firstinterest settlement rate;
   dcl double par frequency basis r;
   method init();
      issue=mdy(2, 28, 2016);
      firstinterest=mdy(8, 31, 2016);
      settlement=mdy(5, 1, 2016);
      rate=0.1;
      par=1000;
      frequency=2;
      basis=1;
      r=finance('accrint', issue, firstinterest,
         settlement, rate, par, frequency, basis);
     put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=17.1225513616818
```

FINANCE ACCRINTM Function

Computes the accrued interest for a security that pays interest at maturity.

Category:	Financial
Returned data type:	DOUBLE

Syntax

FINANCE('ACCRINTM', *issue*, *settlement*, *rate*, *par-value*, [*basis*]);

Required Arguments

issue
specifies the issue date of the security.

Requirement *Issue* is a SAS date.

Data type DOUBLE

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

par-value
specifies the par value of the security. If you omit *par-value*, SAS uses the value `$1000`.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Accrued Interest: ACCRINTM

The following example computes the accrued interest for a security that pays interest at maturity.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double issue maturity rate;
   dcl double par basis r;
   method init();
      issue=mdy(2, 28, 2015);
      maturity=mdy(8, 31, 2015);
      rate=0.1;
      par=1000;
      basis=0;
      r=finance('accrintm', issue, maturity, rate, par, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=50.5555555555555
```

FINANCE AMORDEGRC Function

Computes the depreciation for each accounting period by using a depreciation coefficient.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('AMORDEGRC', *cost*, *date-purchased*, *first-period*, *salvage*, *period*, *rate*, [*basis*]);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

date-purchased
specifies the date of the purchase of the asset.

Requirement *Date-purchased* is a SAS date.

Data type DOUBLE

first-period
specifies the date of the end of the first period.

Requirement *First-period* is a SAS date.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

period
specifies the depreciation period.

Data type DOUBLE

rate
specifies the rate of depreciation.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

> **TIP** When the first argument of the FINANCE function is AMORDEGRC and the value of *basis* is 2, the function returns a missing value.

Data type DOUBLE

Example: Computing Depreciation: AMORDEGRC

The following program computes the depreciation for each accounting period by using a depreciation coefficient.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost datepurchased firstperiod salvage;
   dcl double period rate basis r;
   method init();
      cost=2400;
      datepurchased=mdy(8, 19, 2016);
      firstperiod=mdy(12, 31, 2016);
      salvage=300;
      period=1;
      rate=0.15;
      basis=1;
      r=finance('amordegrc', cost, datepurchased,
         firstperiod, salvage, period, rate, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=776
```

FINANCE AMORLINC Function

Computes the depreciation for each accounting period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('AMORLINC', *cost*, *date-purchased*, *first-period*, *salvage*, *period*, *rate*, [*basis*]);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

date-purchased
specifies the date of the purchase of the asset.

Requirement *Date-purchased* is a SAS date.

Data type DOUBLE

first-period
specifies the date of the end of the first period.

Requirement *First-period* is a SAS date.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

period
specifies the depreciation period.

Data type DOUBLE

rate
specifies the rate of depreciation.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

TIP When the first argument of the FINANCE function is AMORLINC and the value of *basis* is 2, the function returns a missing value.

Data type DOUBLE

Example: Computing Description: AMORLINC

The following program computes the depreciation for each accounting period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost dp fp salvage;
   dcl double period rate basis r;
   method init();
      cost=2400;
      dp=mdy(9, 30, 2016);
      fp=mdy(12, 31, 2016);
      salvage=245;
      period=0;
      rate=0.115;
      basis=0;
      r=finance('amorlinc', cost, dp, fp, salvage, period, rate,
basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=69
```

FINANCE COUPDAYBS Function

Computes the number of days from the beginning of the coupon period to the settlement date.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPDAYBS', *settlement*, *maturity*, *frequency*, [*basis*]);

Required Arguments

settlement

specifies the settlement date of the security. The security settlement date is the date after the issue date when the security is traded to the buyer.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity

specifies the maturity date of the security. The maturity date is the date on which the security expires.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

frequency

specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360

Numeric Value	String Value	Day Count Method
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: COUPDAYBS

The following program computes the number of days from the beginning of the coupon period to the settlement date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity frequency basis r;
   method init();
      settlement=mdy(12,30,2013);
      maturity=mdy(11,29,2016);
      frequency=4;
      basis=2;
      r=finance('coupdaybs', settlement, maturity, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=31
```

Note: Dates should be entered using the DATE function, or as results of other formulas or functions. For example, use DATE(2016,5,23) for the 23rd day of May 2016. Problems can occur if dates are entered as text.

FINANCE COUPDAYS Function

Computes the number of days in the coupon period that contains the settlement date.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPDAYS', *settlement*, *maturity*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual

Numeric Value	String Value	Day Count Method
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: COUPDAYS

The following program computes the number of days in the coupon period that contains the settlement date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity frequency basis r;
   method init();
      settlement=mdy(1,25,2015);
      maturity=mdy(11,15,2016);
      frequency=2;
      basis=1;
      r=finance('coupdays', settlement, maturity, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=181
```

FINANCE COUPDAYSNC Function

Computes the number of days from the settlement date to the next coupon date.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPDAYSNC', *settlement*, *maturity*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: COUPDAYSNC

The following program computes the number of days from the settlement date to the next coupon date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity frequency basis r;
   method init();
      settlement=mdy(1,25,2007);
      maturity=mdy(11,15,2008);
      frequency=2;
      basis=1;
      r=finance('coupdaysnc', settlement, maturity, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=110
```

FINANCE COUPNCD Function

Computes the next coupon date after the settlement date.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPNCD', *settlement*, *maturity*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: COUPNCD

The following program computes the next coupon date after the settlement date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity frequency basis r;
   method init();
      settlement=mdy(1, 25, 2007);
      maturity=mdy(11, 15, 2008);
      frequency=2;
```

```
      basis=1;
      r=finance('coupncd', settlement, maturity, frequency, basis);
      put r date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
15MAY07
```

Note: *r* is a numeric SAS value and can be printed using the DATE7 format.

FINANCE COUPNUM Function

Computes the number of coupons that are payable between the settlement date and the maturity date.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPNUM', *settlement*, *maturity*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: COUPNUM

The following program computes the number of coupons that are payable between the settlement date and the maturity date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity frequency basis r;
   method init();
      settlement=mdy(1,25,2015);
      maturity=mdy(11,15,2016);
      frequency=2;
      basis=1;
      r=finance('coupnum', settlement, maturity, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=4
```

FINANCE COUPPCD Function

Computes the previous coupon date before the settlement date.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('COUPPCD', *settlement*, *maturity*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual

Numeric Value	String Value	Day Count Method
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: COUPPCD

The following program computes the previous coupon date before the settlement date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity frequency basis r;
   method init();
      settlement=mdy(1, 25, 2007);
      maturity=mdy(11, 15, 2008);
      frequency=2;
      basis=1;
      r=finance('couppcd', settlement, maturity, frequency, basis);
      put r date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
15NOV06
```

FINANCE CUMIPMT Function

Computes the cumulative interest paid between two periods.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('CUMIPMT', *rate*, *nper*, *pv*, *start-period*, *end-period*, [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently.

Data type DOUBLE

start-period
specifies the first period in the calculation. Payment periods are numbered beginning with 1.

Data type DOUBLE

end-period
specifies the last period in the calculation.

Data type DOUBLE

Optional Argument

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: CUMIPMT

The following program computes the cumulative interest that is paid between two periods.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate nper pv startperiod endperiod type r;
   method init();
      rate=0.09;
      nper=30;
      pv=125000;
      startperiod=13;
      endperiod=24;
      type=0;
      r=finance('cumipmt', rate, nper, pv, startperiod, endperiod,
type);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-94054.8203251095
```

FINANCE CUMPRINC Function

Computes the cumulative principal that is paid on a loan between two periods.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('CUMPRINC', *rate*, *nper*, *pv*, *start-period*, *end-period*, [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently.

Data type DOUBLE

start-period
specifies the first period in the calculation. Payment periods are numbered beginning with 1.

Data type DOUBLE

end-period
specifies the last period in the calculation.

Data type DOUBLE

Optional Argument

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: CUMPRINC

The following program computes the cumulative principal that is paid on a loan between two periods.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate nper pv startperiod endperiod type r;
   method init();
      rate=0.09;
      nper=30;
      pv=125000;
      startperiod=13;
      endperiod=24;
      type=0;
      r=finance('cumprinc', rate, nper, pv, startperiod, endperiod,
type);
      put r=;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-51949.7067612251
```

FINANCE DB Function

Computes the depreciation of an asset for a specified period by using the fixed-declining balance method.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('DB', *cost*, *salvage*, *life*, *period*, [*month*]);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

life
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type DOUBLE

period
specifies the period for which you want to calculate the depreciation. *Period* must use the same time units as *life*.

Data type DOUBLE

Optional Argument

month
specifies the number of months (month is an optional numeric argument). If month is omitted, it defaults to a value of 12.

Data type DOUBLE

Example: Computing Description: DB

The following program computes the depreciation of an asset for a specified period by using the fixed-declining balance method.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost salvage life period month r;
   method init();
      cost=1000000;
      salvage=100000;
      life=6;
      period=2;
      month=7;
      r=finance('db', cost, salvage, life, period, month);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=259639.416666666
```

FINANCE DDB Function

Computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('DDB', *cost*, *salvage*, *life*, *period*, [*factor*]);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

life
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type DOUBLE

period
specifies the period for which you want to calculate the depreciation. *Period* must use the same time units as *life*.

Data type DOUBLE

Optional Argument

factor
specifies the rate at which the balance declines. If *factor* is omitted, it is assumed to be 2 (the double-declining balance method).

Data type DOUBLE

Example: Computing Description: DDB

The following program computes the depreciation of an asset for a specified period by using the double-declining balance method or some other method that you specify.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost salvage life period factor r;
   method init();
```

```
      cost=2400;
      salvage=300;
      life=10*365;
      period=1;
      factor=.;
      r=finance('ddb', cost, salvage, life, period, factor);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1.31506849315068
```

FINANCE DISC Function

Computes the discount rate for a security.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('DISC', *settlement*, *maturity*, *price*, *redemption*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

price
specifies the price of security per $100 face value.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: DISC

The following program computes the discount rate for a security.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity price redemption basis r;
   method init();
      settlement=mdy(1, 25, 2007);
      maturity=mdy(6, 15, 2007);
      price=97.975;
      redemption=100;
      basis=1;
      r=finance('disc', settlement, maturity, price, redemption,
basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.05242021276595
```

FINANCE DOLLARDE Function

Converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('DOLLARDE', *fractional-dollar*, *fraction*);

Required Arguments

fractional-dollar
specifies the number expressed as a fraction.

Data type DOUBLE

fraction
specifies the whole number to use in the denominator of a fraction.

Data type DOUBLE

Example: Computing Description: DOLLARDE

The following program converts a dollar price, expressed as a fraction, to a dollar price, expressed as a decimal number.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double fractionaldollar fraction r;
   method init();
      fractionaldollar=1.125;
      fraction=16;
      r=finance('dollarde', fractionaldollar, fraction);
      put r=;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1.78125
```

FINANCE DOLLARFR Function

Converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('DOLLARFR', *decimal-dollar*, *fraction*);

Required Arguments

decimal-dollar
specifies a decimal number.

Data type DOUBLE

fraction
specifies the whole number to use in the denominator of a fraction.

Data type DOUBLE

Example: Computing Description: DOLLARFR

The following program converts a dollar price, expressed as a decimal number, to a dollar price, expressed as a fraction.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double decimaldollar fraction r;
   method init();
      decimaldollar=1.125;
```

```
      fraction=16;
      r=finance('dollarfr', decimaldollar, fraction);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1.02
```

In fraction form, the value of *r* is read as $1\frac{2}{16}$.

FINANCE DURATION Function

Computes the annual duration of a security with periodic interest payments.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('DURATION', *settlement*, *maturity*, *coupon*, *yield*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

coupon
specifies the annual coupon rate of the security.

Requirement *Coupon* is provided as a numeric value and not as a percentage.

Data type DOUBLE

yield
specifies the annual yield of the security.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: DURATION

The following program computes the annual duration of a security with periodic interest payments.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity couponrate yield
      frequency basis r;
      method init();
      settlement=mdy(1, 1, 2008);
      maturity=mdy(1, 1, 2016);
      couponrate=0.08;
```

```
        yield=0.09;
        frequency=2;
        basis=1;
        r=finance('duration', settlement, maturity, couponrate,
           yield, frequency, basis);
        put r=;
     end;
  enddata;
  run;
  quit;
```

SAS writes the following output to the log:

```
r=5.99377495554518
```

FINANCE EFFECT Function

Computes the effective annual interest rate.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('EFFECT', *nominal-rate*, *npery*);

Required Arguments

nominal-rate
specifies the nominal interest rate.

Data type DOUBLE

npery
specifies the number of compounding periods per year.

Data type DOUBLE

Example: Computing Description: EFFECT

The following program computes the effective annual interest rate.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double nominalrate npery r;
   method init();
      nominalrate=0.0525;
      npery=4;
      r=finance('effect', nominalrate, npery);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.05354266737075
```

FINANCE FV Function

Computes the future value of an investment.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('FV', *rate*, *nper*, [*payment*], [*present-value*], [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

Optional Arguments

payment
specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, *payment* contains principal and interest but no fees and taxes. If *payment* is omitted, you must include the *present-value* argument.

Data type DOUBLE

present-value
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *present-value* is omitted, it is assumed to be 0 (zero), and you must include the *payment* argument.

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: FV

The following program computes the future value of an investment.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate nper payment present_value type r;
   method init();
      rate=0.06/12;
      nper=10;
      payment=-200;
      present_value=-500;
      type=1;
      r=finance('fv', rate, nper, payment, present_value, type);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=2581.40337406018
```

FINANCE FVSCHEDULE Function

Computes the future value of the initial principal after applying a series of compound interest rates.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('FVSCHEDULE', *principal*, *schedule-1*, *schedule-2* ...);

Required Arguments

principal
specifies the present value.

Data type DOUBLE

schedule
specifies the sequence of interest rates to apply.

Requirement *Schedule* rates are provided as numeric values and not as percentages.

Data type DOUBLE

Example: Computing Description: FVSCHEDULE

The following program computes the future value of the initial principal after applying a series of compound interest rates.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double principal r1 r2 r3 r;
   method init();
      principal=1;
      r1=0.09;
      r2=0.11;
      r3=0.1;
      r=finance('fvschedule', principal, r1, r2, r3);
      put r=;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1.33089
```

FINANCE INTRATE Function

Computes the interest rate for a fully invested security.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('INTRATE', *settlement*, *maturity*, *investment*, *redemption*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

investment
specifies the amount that is invested in the security.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

Optional Argument

basis

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: INTRATE

The following program computes the interest rate for a fully invested security.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity investment redemption basis r;
   method init();
      settlement=mdy(2, 15, 2008);
      maturity=mdy(5, 15, 2008);
      investment=1000000;
      redemption=1014420;
      basis=2;
      r=finance('intrate', settlement, maturity, investment,
redemption, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.05768
```

FINANCE IPMT Function

Computes the interest payment for an investment for a specified period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('IPMT', *rate*, *period*, *nper*, *pv*, [*fv*], [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

period
specifies the period for which you want to calculate the depreciation. *Period* must use the same units as *life*.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *fv* argument.

Data type DOUBLE

Optional Arguments

fv
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: IPMT

The following program computes the interest payment for an investment for a specified period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate per nper pv fv type r;
   method init();
      rate=0.1/12;
      per=2;
      nper=3;
      pv=100;
      fv=.;
      type=.;
      r=finance('ipmt', rate, per, nper, pv, fv, type);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-0.5578575637229
```

FINANCE IRR Function

Computes the internal rate of return for a series of cash flows.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('IRR', *value-1*, *value-2*, ..., *value-n*);

Required Argument

value
specifies a list of numeric arguments that contain numbers for which you want to calculate the internal rate of return.

Data type DOUBLE

Example: Computing Description: IRR

The following program computes the internal rate of return for a series of cash flows.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double v1 v2 v3 v4 v5 v6 r;
   method init();
      v1=-70000;
      v2=12000;
      v3=15000;
      v4=18000;
      v5=21000;
      v6=26000;
      r=finance('irr', v1, v2, v3, v4, v5, v6);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.08663094803653
```

FINANCE ISPMT Function

Calculates the interest paid during a specific period of an investment.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('ISPMT', *interest-rate*, *period*, *number-payments*, *pv*);

Required Arguments

interest-rate
specifies the interest rate for the investment.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

period
specifies the period for which you want to calculate the interest rate. *Period* must be a value between 1 and *number-payments*.

Data type DOUBLE

number-payments
specifies the number of payments for the annuity.

Data type DOUBLE

pv
specifies the loan amount or present value of the payments.

Data type DOUBLE

Example: Computing Description: ISPMT

The following program computes the interest payment for a $5,000 investment that earns 7.5% annually for two years. The interest payment is calculated for the eighth month.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double interest;
   method init();
      interest=finance('ispmt', 0.075/12, 8, 2*12, 5000);
      put interest=;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
interest=-20.8333333333333
```

FINANCE MDURATION Function

Computes the Macaulay modified duration for a security with an assumed face value of $100.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('MDURATION', *settlement*, *maturity*, *coupon*, *yield*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

coupon
specifies the annual coupon rate of the security.

Requirement *Coupon* is provided as a numeric value and not as a percentage.

Data type DOUBLE

yield
specifies the annual yield of the security.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: MDURATION

The following program computes the Macaulay modified duration for a security with an assumed face value of $100.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity couponrate yield frequency basis r;
   method init();
      settlement=mdy(1, 1, 2008);
      maturity=mdy(1, 1, 2016);
      couponrate=0.08;
      yield=0.09;
      frequency=2;
      basis=1;
      r=finance('mduration', settlement, maturity, couponrate, yield,
         frequency, basis);
      put r=;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=5.73566981391883
```

FINANCE MIRR Function

Computes the internal rate of return where positive and negative cash flows are financed at different rates.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('MIRR', *value-1*, ..., *value-n*, *finance-rate*, *reinvest-rate*);

Required Arguments

value
specifies a list of numeric arguments that contain numbers. These numbers represent a series of payments (negative values) and income (positive values) that occur at regular periods. *Value* must contain at least one positive value and one negative value to calculate the modified internal rate of return.

Data type DOUBLE

finance-rate
specifies the interest rate that you pay on the money that is used in the cash flows.

Requirement *Finance-rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

reinvest-rate
specifies the interest rate that you receive on the cash flows as you reinvest them.

Requirement *Reinvest-rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

Example: Computing Description: MIRR

The following program computes the internal rate of return where positive and negative cash flows are financed at different rates.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double v1 v2 v3 v4 financerate reinvestrate r;
   method init();
      v1=-1000;
      v2=3000;
      v3=4000;
      v4=5000;
      financerate=0.08;
      reinvestrate=0.10;
      r=finance('mirr', v1, v2, v3, v4, financerate, reinvestrate);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1.35314201717001
```

FINANCE NOMINAL Function

Computes the annual nominal interest rates.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('NOMINAL', *effective-rate*, *npery*);

Required Arguments

effective-rate
specifies the effective interest rate.

Requirement *Effective-rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

npery
specifies the number of compounding periods per year.

Data type DOUBLE

Example: Computing Description: NOMINAL

The following program computes the annual nominal interest rate.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double effectrate npery r;
   method init();
      effectrate=0.08;
      npery=4;
      r= finance('nominal', effectrate, npery);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.07770618763309
```

FINANCE NPER Function

Computes the number of periods for an investment.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('NPER', *rate*, *payment*, *pv*, [*fv*], [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

payment
specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, *payment* contains principal and interest but no other fees or taxes. If *payment* is omitted, you must include the *pv* argument.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *payment* argument.

Data type DOUBLE

Optional Arguments

fv
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: NPER

The following program computes the number of periods for an investment.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate payment pv fv type r;
   method init();
      rate=0.08;
      payment=200;
      pv=1000;
      fv=0;
      type=0;
      r=finance('nper', rate, payment, pv, fv, type);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-4.37198135126657
```

FINANCE NPV Function

Computes the net present value of an investment based on a series of periodic cash flows and a discount rate.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('NPV', *rate*, *value-1*, [, ... *value-n*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

value
represents the sequence of the cash flows.

Data type DOUBLE

Example: Computing Description: NPV

The following program computes the net present value of an investment based on a series of periodic cash flows and a discount rate.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate v1 v2 v3 r;
   method init();
      rate=0.08;
      v1=200;
      v2=1000;
      v3=0.;
      r=finance('npv', rate, v1, v2, v3);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1042.52400548696
```

FINANCE ODDFPRICE Function

Computes the price of a security per $100 face value with an odd first period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('ODDFPRICE', *settlement*, *maturity*, *issue*, *first-coupon*, *rate*, *yield*, *redemption*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

issue
specifies the issue date of the security.

Requirement *Issue* is a SAS date.

Data type DOUBLE

first-coupon
specifies the first coupon date of the security.

Requirement *First-coupon* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

yield
specifies the annual yield of the security.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: ODDFPRICE

The following program computes the price of a security per $100 face value with an odd first period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity issue firstcoupon
   rate yield redemption frequency basis r;
   method init();
      settlement=mdy(1, 15, 93);
      maturity=mdy(1, 1, 98);
      issue=mdy(1, 1, 93);
      firstcoupon=mdy(7, 1, 94);
      rate=0.07;
      yield=0.06;
      redemption=100;
      frequency=2;
      basis=0;
      r=finance('oddfprice', settlement, maturity, issue, firstcoupon,
         rate, yield, redemption, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=103.941039839766
```

FINANCE ODDFYIELD Function

Computes the yield of a security with an odd first period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('ODDFYIELD', *settlement*, *maturity*, *issue*, *first-coupon*, *rate*, *price*, *redemption*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

issue
specifies the issue date of the security.

Requirement *Issue* is a SAS date.

Data type DOUBLE

first-coupon
specifies the first coupon date of the security.

Requirement *First-coupon* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

price
specifies the price of the security per $100 face value.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: ODDFYIELD

The following program computes the interest of a yield with an odd first period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity issue firstcoupon
      rate price redemption frequency basis r;
      method init();
      settlement=mdy(1, 15, 93);
      maturity=mdy(1, 1, 98);
      issue=mdy(1, 1, 93);
      firstcoupon=mdy(7, 1, 94);
      rate=0.07;
      price=103.94103984;
      redemption=100;
      frequency=2;
      basis=0;
      r=finance('oddfyield', settlement, maturity, issue, firstcoupon,
         rate, price, redemption, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.05999999999946
```

FINANCE ODDLPRICE Function

Computes the price of a security per $100 face value with an odd last period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('ODDLPRICE', *settlement*, *maturity*, *last-interest*, *rate*, *yield*, *redemption*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

last-interest
specifies the last coupon date of the security.

Requirement *Last-interest* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

yield
specifies the annual yield of the security.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360

Numeric Value	String Value	Day Count Method
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: ODDLPRICE

The following program computes the price of a security per $100 face value with an odd last period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data;
   dcl double settlement maturity lastinterest
      rate yield redemption frequency basis r;
   method init();
      settlement=mdy(2, 7, 2008);
      maturity=mdy(6, 15, 2008);
      lastinterest=mdy(10, 15, 2007);
      rate=0.0375;
      yield=0.0405;
      redemption=100;
      frequency=2;
      basis=0;
      r=finance('oddlprice', settlement, maturity, lastinterest,
         rate, yield, redemption, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=99.8782860147213
```

FINANCE ODDLYIELD Function

Computes the yield of a security with an odd last period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('ODDLYIELD', *settlement*, *maturity*, *last-interest*, *rate*, *price*, *redemption*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

last-interest
specifies the last coupon date of the security.

Requirement *Last-interest* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

price
specifies the price of the security per $100 face value.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: ODDLYIELD

The following program computes the yield of a security with an odd last period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity lastinterest
      rate price redemption frequency basis r;
   method init();
      settlement=mdy(2, 7, 2008);
      maturity=mdy(6, 15, 2008);
      lastinterest=mdy(10, 15, 2007);
      rate=0.0375;
      price=99.878286015;
      redemption=100;
      frequency=2;
      basis=0;
      r=finance('oddlyield', settlement, maturity, lastinterest,
         rate, price, redemption, frequency, basis);
      put r=;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
r=0.04049999999213
```

FINANCE PMT Function

Computes the periodic payment of an annuity.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('PMT', *rate*, *nper*, *pv*, [*fv*], [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *fv* argument.

Data type DOUBLE

Optional Arguments

fv
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: PMT

The following program computes the periodic payment for an annuity.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate nper pv fv type r;
   method init();
      rate=0.08;
      nper=5;
      pv=91;
      fv=3;
      type=0;
      r=finance('pmt', rate, nper, pv, fv, type);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-23.3029067292826
```

FINANCE PPMT Function

Computes the payment on the principal for an investment for a specified period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('PPMT', *rate*, *period*, *nper*, *pv*, [*fv*], [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

period
specifies the period.

Range: 1–*nper*

Data type DOUBLE

nper
specifies the number of payment periods.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *fv* argument.

Data type DOUBLE

Optional Arguments

fv
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: PPMT

The following program computes the payment on the principal for an investment for a specified period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate period nper pv fv type r;
   method init();
      rate=0.08;
      period=10;
      nper=10;
      pv=200000;
      fv=0;
      type=0;
      r=finance('ppmt', rate, period, nper, pv, fv, type);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-27598.0534624213
```

FINANCE PRICE Function

Computes the price of a security per $100 face value that pays periodic interest.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('PRICE', *settlement*, *maturity*, *rate*, *yield*, *redemption*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

yield
specifies the annual yield of the security.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: PRICE

The following program computes the price of a security per $100 face value that pays periodic interest.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity rate yield redemption
      frequency basis r;
   method init();
      settlement=mdy(2,15,2008);
      maturity=mdy(11,15,2017);
      rate=0.0575;
      yield=0.065;
      redemption=100;
      frequency=2;
      basis=0;
      r=finance('price', settlement, maturity, rate, yield,
         redemption, frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=94.6343616213221
```

FINANCE PRICEDISC Function

Computes the price of a discounted security per $100 face value.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('PRICEDISC', *settlement*, *maturity*, *discount*, *redemption*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

discount
specifies the discount rate of the security.

Requirement *Discount* is provided as a numeric value and not as a percentage.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: PRICEDISC

The following program computes the price of a discounted security per $100 face value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity discount redemption basis r;
   method init();
      settlement=mdy(2, 15, 2008);
      maturity=mdy(11, 15, 2017);
      discount=0.0525;
      redemption=100;
      basis=0;
      r=finance('pricedisc', settlement, maturity, discount,
redemption,
         basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=48.8125
```

FINANCE PRICEMAT Function

Computes the price of a security per $100 face value that pays interest at maturity.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('PRICEMAT', *settlement*, *maturity*, *issue*, *rate*, *yield*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

issue
specifies the issue date of the security.

Requirement *Issue* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

yield
specifies the annual yield of the security.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: PRICEMAT

The following program computes the price of a security per $100 face value that pays interest at maturity.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity issue rate yield basis r;
   method init();
      settlement=mdy(2, 15, 2008);
      maturity=mdy(4, 13, 2008);
      issue=mdy(11, 11, 2007);
      rate=0.061;
      yield=0.061;
      basis=0;
      r=finance('pricemat', settlement, maturity, issue, rate, yield,
basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=99.9844988755569
```

FINANCE PV Function

Computes the present value of an investment.

Category:	Financial
Returned data type:	DOUBLE

Syntax

FINANCE('PV', *rate*, *nper*, *payment*, [*fv*], [*type*]);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

nper
specifies the total number of payment periods.

Data type DOUBLE

payment
specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, *payment* contains principal and interest but no other fees or taxes.

Data type DOUBLE

Optional Arguments

fv
specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

type
specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: PV

The following program computes the present value of an investment.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate nper payment fv type r;
   method init();
      rate=0.05;
      nper=10;
      payment=1000;
      fv=200;
      type=0;
      r=finance('pv', rate, nper, payment, fv, type);
```

```
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=-7844.51757989297
```

FINANCE RATE Function

Computes the interest rate per period of an annuity.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('RATE', *nper*, *payment*, *pv*, [*fv*], [*type*]);

Required Arguments

nper
specifies the total number of payment periods.

Data type DOUBLE

payment
specifies the payment that is made each period; the payment cannot change over the life of the annuity. Typically, *payment* contains principal and interest but no other fees or taxes. If *payment* is omitted, you must include the *pv* argument.

Data type DOUBLE

pv
specifies the present value or the lump-sum amount that a series of future payments is worth currently. If *pv* is omitted, it is assumed to be 0 (zero), and you must include the *fv* argument.

Data type DOUBLE

Optional Arguments

fv

specifies the future value or a cash balance that you want to attain after the last payment is made. If *fv* is omitted, it is assumed to be 0 (for example, the future value of a loan is 0).

Data type DOUBLE

type

specifies the number 0 or 1 and indicates when payments are due. If *type* is omitted, it is assumed to be 0.

If payments are due at the end of the period, then either omit the *type* argument or set it to 0. If payments are due at the beginning of the period, then set *type* to 1.

Data type DOUBLE

Example: Computing Description: RATE

The following program computes the interest rate per period of an annuity.

```
proc ds2;
data test(overwrite=yes);
   dcl double nper payment pv r;
   method init();
      nper=4;
      payment=-2481;
      pv=8000;
      r=finance('rate', nper, payment, pv);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.09214768406875
```

FINANCE RECEIVED Function

Computes the amount that is received at maturity for a fully invested security.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('RECEIVED', *settlement*, *maturity*, *investment*, *discount*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

investment
specifies the amount that is invested in the security.

Data type DOUBLE

discount
specifies the discount rate of the security.

Requirement *Discount* is provided as a numeric value and not as a percentage.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: RECEIVED

The following program computes the amount that is received at maturity for a fully invested security.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity investment discount basis r;
   method init();
      settlement=mdy(2, 15, 2008);
      maturity=mdy(5, 15, 2008);
      investment=1000000;
      discount=0.0575;
      basis=2;
      r=finance('received', settlement, maturity, investment,
discount, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=1014584.6544071
```

FINANCE SLN Function

Computes the straight-line depreciation of an asset for one period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('SLN', *cost*, *salvage*, *life*);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

life
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type DOUBLE

Example: Computing Description: SLN

The following program computes the straight-line depreciation of an asset for one period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost salvage life r;
   method init();
      cost=2000;
      salvage=200;
      life=11;
      r=finance('sln', cost, salvage, life);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=163.636363636363
```

FINANCE SYD Function

Computes the sum-of-years digits depreciation of an asset for a specified period.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('SYD', *cost*, *salvage*, *life*, *period*);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

life
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type DOUBLE

period
specifies a period in the same time units that are used for the argument *life*.

Data type DOUBLE

Example: Computing Description: SYD

The following program computes the sum-of-years digits depreciation of an asset for a specified period.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost salvage life period r;
   method init();
      cost=2000;
      salvage=200;
      life=11;
      period=1;
      r=finance('syd', cost, salvage, life, period);
```

```
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=300
```

FINANCE TBILLEQ Function

Computes the bond-equivalent yield for a treasury bill.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('TBILLEQ', *settlement*, *maturity*, *discount*);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

discount
specifies the discount rate of the security.

Requirement *Discount* is provided as a numeric value and not as a percentage.

Data type DOUBLE

Example: Computing Description: TBILLEQ

The following program computes the bond-equivalent yield for a treasury bill.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity discount r;
   method init();
      settlement=mdy(3, 31, 2008);
      maturity=mdy(6, 1, 2008);
      discount=0.0914;
      r=finance('tbilleq', settlement, maturity, discount);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.09415149356594
```

FINANCE TBILLPRICE Function

Computes the price of a treasury bill per $100 face value.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('TBILLPRICE', *settlement*, *maturity*, *discount*);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

discount
specifies the discount rate of the security.

Requirement *Discount* is provided as a numeric value and not as a percentage.

Data type DOUBLE

Example: Computing Description: TBILLPRICE

The following program computes the price of a treasury bill per $100 face value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity discount r;
   method init();
      settlement=mdy(3, 31, 2008);
      maturity=mdy(6, 1, 2008);
      discount=0.09;
      r=finance('tbillprice', settlement, maturity, discount);
      put r=;
   end;
enddata;
run;
quit;
```

The value of *r* that is returned is 98.45.

FINANCE TBILLYIELD Function

Computes the yield for a treasury bill.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('TBILLYIELD', *settlement*, *maturity*, *price*);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

price
specifies the price of the security per $100 face value.

Data type DOUBLE

Example: Computing Description: TBILLYIELD

The following program computes the yield for a treasury bill.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity price r;
   method init();
      settlement=mdy(3, 31, 2008);
      maturity=mdy(6, 1, 2008);
      price=98;
      r=finance('tbillyield', settlement, maturity, price);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.11849901250822
```

FINANCE VDB Function

Computes the depreciation of an asset for a specified or partial period by using a declining balance method.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('VDB', *cost*, *salvage*, *life*, *start-period*, *end-period*, [*factor*], [*noswitch*]);

Required Arguments

cost
specifies the initial cost of the asset.

Data type DOUBLE

salvage
specifies the value at the end of the depreciation (also called the salvage value of the asset).

Data type DOUBLE

life
specifies the number of periods over which the asset is depreciated (also called the useful life of the asset).

Data type DOUBLE

start-period
specifies the first period in the calculation. Payment periods are numbered beginning with 1.

Data type DOUBLE

end-period
specifies the last period in the calculation.

Data type DOUBLE

Optional Arguments

factor
specifies the rate at which the balance declines. If *factor* is omitted, it is assumed to be 2 (the double-declining balance method).

Data type DOUBLE

noswitch
specifies a logical value that determines whether to switch to straight-line depreciation when the depreciation is greater than the declining balance calculation. If *noswitch* is omitted, it is assumed to be 1.

Data type DOUBLE

Example: Computing Description: VDB

The following program computes the depreciation of an asset for a specified or partial period by using a declining balance method.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double cost salvage life startperiod endperiod factor r;
   method init();
      cost=2400;
      salvage=300;
      life=10;
      startperiod=0;
      endperiod=1;
      factor=1.5;
      r=finance('vdb', cost, salvage, life, startperiod, endperiod,
factor);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=360
```

FINANCE XIRR Function

Computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('XIRR', *values*, *dates*, [*guess*]);

Required Arguments

values

specifies a series of cash flows that corresponds to a schedule of payments in dates. The first payment is optional and corresponds to a cost or payment that occurs at the beginning of the investment. If the first value is a cost or payment, it must be a negative value. All succeeding payments are discounted based on a 365-day year. The series of values must contain at least one positive value and one negative value.

Data type DOUBLE

dates

specifies a schedule of payment dates that corresponds to the cash flow payments. The first payment date indicates the beginning of the schedule of payments. All other dates must be later than this date, but they can occur in any order.

Requirement *Dates* are SAS dates.

Data type DOUBLE

Optional Argument

guess

specifies an optional number that you guess is close to the result of XIRR.

Data type DOUBLE

Example: Computing Description: XIRR

The following program computes the internal rate of return for a schedule of cash flows that is not necessarily periodic.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
```

```
      dcl double v1 v2 v3 v4 v5 d1 d2 d3 d4 d5 r;
      method init();
         v1=-10000; d1=mdy(1, 1, 2008);
         v2=2750; d2=mdy(3, 1, 2008);
         v3=4250; d3=mdy(10, 30, 2008);
         v4=3250; d4=mdy(2, 15, 2009);
         v5=2750; d5=mdy(4, 1, 2009);
         r=finance('xirr', v1, v2, v3, v4, v5, d1, d2, d3, d4, d5, 0.1);
         put r=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log:

```
r=0.37336253351883
```

FINANCE XNPV Function

Computes the net present value for a schedule of cash flows that is not necessarily periodic.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('XNPV', *rate*, *values*, *dates*);

Required Arguments

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

values
specifies a series of cash flows that corresponds to a schedule of payments in dates. The first payment is optional and corresponds to a cost or payment that occurs at the beginning of the investment. If the first value is a cost or payment, it must be a negative value. All succeeding payments are discounted based on a 365-day year. The series of values must contain at least one positive value and one negative value.

Data type DOUBLE

dates
specifies a schedule of payment dates that corresponds to the cash flow payments. The first payment date indicates the beginning of the schedule of payments. All other dates must be later than this date, but they can occur in any order.

Requirement *Dates* are SAS dates.

Data type DOUBLE

Example: Computing Description: XNPV

The following program computes the net present value for a schedule of cash flows that is not necessarily periodic.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double rate v1 v2 v3 v4 v5 d1 d2 d3 d4 d5 r;
   method init();
      rate=.09;
      v1=-10000; d1=mdy(1, 1, 2008);
      v2=2750; d2=mdy(3, 1, 2008);
      v3=4250; d3=mdy(10, 30, 2008);
      v4=3250; d4=mdy(2, 15, 2009);
      v5=2750; d5=mdy(4, 1, 2009);
      r=finance('xnpv', rate, v1, v2, v3, v4, v5, d1, d2, d3, d4, d5);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=2086.64760203153
```

FINANCE YIELD Function

Computes the yield on a security that pays periodic interest.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('YIELD', *settlement*, *maturity*, *rate*, *price*, *redemption*, *frequency*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

price
specifies the price of the security per $100 face value.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

frequency
specifies the number of coupon payments per year. For annual payments, *frequency*=1; for semiannual payments, *frequency*=2; for quarterly payments, *frequency*=4.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: YIELD

The following program computes the yield on a security that pays periodic interest.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity rate pr redemption frequency basis r;
   method init();
      settlement=mdy(2, 15, 2008);
      maturity=mdy(11, 15, 2016);
      rate=0.0575;
      pr=95.04287;
      redemption=100;
      frequency=2;
      basis=0;
      r=finance('yield', settlement, maturity, rate, pr, redemption,
         frequency, basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.06500000688075
```

FINANCE YIELDDISC Function

Computes the annual yield for a discounted security (for example, a treasury bill).

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('YIELDDISC', *settlement*, *maturity*, *price*, *redemption*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

price
specifies the price of the security per $100 face value.

Data type DOUBLE

redemption
specifies the amount to be received at maturity.

Data type DOUBLE

Optional Argument

basis
specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: YIELDDISC

The following program computes the annual yield for a discounted security (for example, a treasury bill).

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity pr redemption basis r;
   method init();
      settlement=mdy(2, 15, 2008);
      maturity=mdy(11, 15, 2016);
      pr=95.04287;
      redemption=100;
      basis=0;
      r=finance('yielddisc', settlement, maturity, pr, redemption,
basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.0059607747836
```

FINANCE YIELDMAT Function

Computes the annual yield of a security that pays interest at maturity.

Category: Financial

Returned data type: DOUBLE

Syntax

FINANCE('YIELDMAT', *settlement*, *maturity*, *issue*, *rate*, *price*, [*basis*]);

Required Arguments

settlement
specifies the settlement date.

Requirement *Settlement* is a SAS date.

Data type DOUBLE

maturity
specifies the maturity date.

Requirement *Maturity* is a SAS date.

Data type DOUBLE

issue
specifies the issue date of the security.

Requirement *Issue* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate.

Requirement *Rate* is provided as a numeric value and not as a percentage.

Data type DOUBLE

price
specifies the price of the security per $100 face value.

Data type DOUBLE

Optional Argument

basis

specifies an optional parameter as a character or numeric value that indicates the type of day count basis to use.

Numeric Value	String Value	Day Count Method
0	"30/360"	US (NASD) 30/360
1	"ACTUAL"	Actual/actual
2	"ACT/360"	Actual/360
3	"ACT/365"	Actual/365
4	"EU30/360"	European 30/360

Data type DOUBLE

Example: Computing Description: YIELDMAT

The following program computes the annual yield of a security that pays interest at maturity.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double settlement maturity issue rate pr basis r;
   method init();
      settlement=mdy(3, 15, 2008);
      maturity=mdy(11, 3, 2008);
      issue=mdy(11, 8, 2007);
      rate=0.0625;
      pr=100.0123;
      basis=0;
      r=finance('yieldmat', settlement, maturity, issue, rate, pr,
basis);
      put r=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
r=0.06095433369153
```

FIND Function

Searches for a specific substring of characters within a character string.

Category: Character

Returned data type: DOUBLE

Tip: Use the "KINDEX Function" in *SAS National Language Support (NLS): Reference Guide* instead to write encoding independent code.

Syntax

FIND(*string*, *substring*[, *modifier(s)*][, *startpos*])

FIND(*string*, *substring*[, *startpos*][, *modifier(s)*])

Required Arguments

string

specifies a character constant, variable, or expression that evaluates or can be coerced to a character string and that will be searched for substrings.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

substring

is a character constant, variable, or expression that evaluates or can be coerced to a character string and that specifies the substring of characters to search for in *string*.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

Optional Arguments

modifier(s)

is a character constant, variable, or expression that specifies one or more modifiers. The following characters, in uppercase or lowercase, can be used as modifiers: I (ignores character case) or T (trims trailing blanks). If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the FIND function with the T modifier.

is a character constant, variable, or expression that specifies one or more modifiers. The following characters, in uppercase or lowercase, can be used as modifiers:

i or I
ignores character case during the search. If this modifier is not specified, FIND searches only for character substrings with the same case as the characters in *substring*.

t or T
trims trailing blanks from *string* and *substring*.

Note: If you want to remove trailing blanks from only one character argument instead of both (or all) character arguments, use the TRIM function instead of the FIND function with the T modifier.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip If *modifier* is a constant, enclose it in quotation marks. Specify multiple constants in a single set of quotation marks. *Modifier* can also be expressed as a variable or an expression.

startpos
is a numeric constant, variable, or expression that specifies the position at which the search should start and the direction of the search. The expression must resolve to a whole number

Data type DOUBLE

Details

The FIND function searches *string* for the first occurrence of the specified *substring*, and returns the position of the first character in that substring. If the substring is not found in *string*, FIND returns a value of 0.

If *startpos* is not specified, FIND starts the search at the beginning of the *string* and searches the *string* from left to right. If *startpos* is specified, the absolute value of *startpos* determines the position at which to start the search. The sign of *startpos* determines the direction of the search.

Value of *startpos*	Action
greater than 0	starts the search at position *startpos* and the direction of the search is to the right. If *startpos* is greater than the length of *string*, FIND returns a value of 0.
less than 0	starts the search at position –*startpos* and the direction of the search is to the left. If –*startpos* is greater than the length of *string*, the search starts at the end of *string*.

Value of *startpos*	Action
equal to 0	returns a value of 0.

Comparisons

- The FIND function searches for substrings of characters in a character string, whereas the FINDC function searches for individual characters in a character string.
- The FIND function and the INDEX function both search for substrings of characters in a character string. However, the INDEX function does not have the *modifiers* nor the *startpos* arguments.

Example

The following program illustrates the FIND function using different data types:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(35) char1 char2 char3;
   dcl varchar(35) varchar1 varchar2 varchar3;
   dcl double i;
   method run();
      i=find('She sells seashells? Yes, she does.', 'she ', 'i');
      put 'literal' i=;
      char1='She sells seashells? Yes, she does.';
      char2='she ';
      char3='i';
      i=find(char1, char2, char3);
      put 'char' i=;
      varchar1='She sells seashells? Yes, she does.';
      varchar2='she ';
      varchar3='i';
      i=find(varchar1, varchar2, varchar3);
      put 'varchar' i=;
      char1='She sells seashells? Yes, she does.';
      char2='she ';
      char3='i';
      i=find(char1, trim(char2), char3);
      put 'trim char' i=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
literal i=1
char i=0
varchar i=1
trim char i=1
```

FINDC Function

Searches a string for any character in a list of characters.

Category: Character

Returned data type: DOUBLE

Tip: Use the “KINDEXC Function” in *SAS National Language Support (NLS): Reference Guide* instead to write encoding independent code.

Syntax

FINDC(*string*, *charlist*[, *startpos*][, *modifiers*])

FINDC(*string*, *charlist*, *modifiers*[, *startpos*])

FINDC(*string*, *charlist*[, *modifiers*])

FINDC(*string*[, *charlist*])

Required Arguments

string

is a character constant, variable, or expression that evaluates or can be coerced to a character string and that specifies the character string to be searched.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

charlist
is a constant, variable, or character expression that initializes a list of characters. FINDC searches for the characters in this list provided that you do not specify the K modifier in the *modifiers* argument. If you specify the K modifier, FINDC searches for all characters that are not in this list of characters. You can add more characters to the list by using other modifiers.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip Enclose a literal string of characters in quotation marks.

Optional Arguments

modifiers
is a character constant, variable, or expression in which each character modifies the action of the FINDC function. The following characters, in uppercase or lowercase, can be used as modifiers:

A
adds alphabetic characters to the list of characters.

B
searches from right to left, instead of from left to right, regardless of the sign of the *startpos* argument.

C
adds control characters to the list of characters.

D
adds digits to the list of characters.

F
adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.

G
adds graphic characters to the list of characters.

H
adds a horizontal tab to the list of characters.

I
ignores character case during the search.

K
searches for any character that does not appear in the list of characters. If you do not specify this modifier, then FINDC searches for any character that appears in the list of characters. The V and K modifiers perform the same function.

L
adds lowercase letters to the list of characters.

N
adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.

O
processes the *charlist* and the *modifiers* arguments only once, rather than every time the FINDC function is called. Using the O modifier in DS2 (excluding WHERE clauses) can make FINDC run faster when you call it in a loop where the *charlist* and the *modifiers* arguments do not change.

P
adds punctuation marks to the list of characters.

S
adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).

T
trims trailing blanks from the *string* and *charlist* arguments. Note that if you want to remove trailing blanks from just one character argument instead of both (or all) character arguments, use the TRIM function instead of the FINDC function with the T modifier.

U
adds uppercase letters to the list of characters.

V
causes all character that are not in the list of characters to be treated as delimiters. If V is not specified, then all characters that are in the list of characters are treated as delimiters. The V and K modifiers perform the same function.

W
adds printable characters to the list of characters.

X
adds hexadecimal characters to the list of characters.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: If *modifiers* is a constant, then enclose it in quotation marks. Specify multiple constants in a single set of quotation marks. *Modifiers* can also be expressed as a variable or an expression. Blanks are ignored.

startpos
is an optional numeric constant, variable, or expression that specifies the position at which the search should start and the direction in which to search. The expression must resolve to a whole number.

Data type: DOUBLE

Details

The FINDC function searches *string* for the first occurrence of the specified characters, and returns the position of the first character found. If no characters are found in *string*, then FINDC returns a value of 0.

The FINDC function allows character arguments to be null. Null arguments are treated as character strings that have a length of zero. Numeric arguments cannot be null.

If *startpos* is not specified, FINDC begins the search at the end of the string if you use the B modifier, or at the beginning of the string if you do not use the B modifier.

If *startpos* is specified, the absolute value of *startpos* specifies the position at which to begin the search. If you use the B modifier, the search always proceeds from right to left. If you do not use the B modifier, the sign of *startpos* specifies the direction in which to search. The following table summarizes the search directions:

Value of *startpos*	**Action**
greater than 0	search begins at position *startpos* and proceeds to the right. If *startpos* is greater than the length of the string, FINDC returns a value of 0.
less than 0	search begins at position –*startpos* and proceeds to the left. If *startpos* is less than the negative of the length of the string, the search begins at the end of the string.
equal to 0	returns a value of 0.

Comparisons

- The FINDC function searches for individual characters in a character string, whereas the FIND function searches for substrings of characters in a character string.
- The FINDC function and the INDEXC function both search for individual characters in a character string. However, the INDEXC function does not have the *modifiers* nor the *startpos* arguments.
- The FINDC function searches for individual characters in a character string, whereas the VERIFY function searches for the first character that is unique to an expression. The VERIFY function does not have the *modifiers* nor the *startpos* arguments.

Examples

Example 1: Searching for Characters in a String

The following program searches a character string and returns the characters that are found.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double j i;
   dcl char c;
   method run();
      j=0;
      do until(j=0);
         j = findc('Hi, ho!','hi',j+1);
         if j= 0 then put 'The End';
         else do;
            c = substr('Hi, ho!', j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=2 c=i
j=5 c=h
The End
```

Example 2: Searching for Characters in a String and Ignoring Case

The following program searches a character string and returns the characters that are found. The I modifier is used to ignore the case of the characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char string charlist c;
   dcl double j i;
   method run();
      string='Hi, ho!';
      charlist='ho';
      j=0;
      do until(j=0);
         j=findc(string,charlist,j+1,'i');
         if j=0 then put 'The End';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=H
j=4 c=
j=5 c=h
j=6 c=o
j=8 c=
The End
```

Example 3: Searching for Characters and Using the K Modifier

The following program searches a character string and returns the characters that do not appear in the character list.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double j;
   dcl char c string charlist;
   method run();
      string='Hi, ho!';
      charlist='hi';
      j=0;
      do until(j = 0);
      j = findc(string,charlist,'k',j+1);
      if j=0 then put 'The End';
         else do;
            c = substr(string,j,1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=H
j=3 c=,
j=6 c=o
j=7 c=!
The End
```

Example 4: Searching for the Characters h, i, and Blank

The following program searches for the three characters h, i, and blank. The characters h and i are in lowercase. The uppercase characters H and I are ignored in this search.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double whereishi;
```

```
   dcl char whatfound;
   method run();
      whereishi=0;
      do until(whereishi=0);
         whereishi=findc('Hi there, Ian!','hi ',whereishi+1);
         if whereishi=0 then put 'The End';
         else do;
            whatfound=substr('Hi there, Ian!',whereishi,1);
            put whereishi= whatfound=;
         end;
     end;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
whereishi=2 whatfound=i
whereishi=3 whatfound=
whereishi=5 whatfound=h
whereishi=10 whatfound=
The End
```

Example 5: Searching for the Characters h and i While Ignoring Case

The following program searches for the four characters h, i, H, and I. FINDC with the i modifier ignores character case during the search.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double whereishi_i;
   dcl char whatfound variable1 variable2 variable3;
   method run();
      whereishi_i=0;
      do until(whereishi_i=0);
         whereishi_i=findc('Hi there, Ian!','hi ',whereishi_i+1);
         if whereishi_i=0 then put 'The End';
            else do;
                whatfound=substr('Hi there, Ian!',whereishi_i,1);
                put whereishi_i= whatfound=;
            end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
whereishi_i=2 whatfound=i
whereishi_i=3 whatfound=
whereishi_i=5 whatfound=h
whereishi_i=10 whatfound=
The End
```

Example 6: Searching for the Characters h and i with Trailing Blanks Trimmed

The following program searches for the two characters h and i. FINDC with the t modifier trims trailing blanks from the string argument and the characters argument.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
dcl char(14) expression1 expression2 expression3 whatfound;
dcl double whereishi_t;
method run();
   whereishi_t=0;
      do until(whereishi_t=0);
         expression1='Hi there, '||'Ian!';
         expression2=kscan('bye or hi',3)||'  ';
         expression3=trim('t   ');

whereishi_t=findc(expression1,expression2,expression3,whereishi_t+1);
         if whereishi_t=0 then put 'The End';
            else do;
               whatfound=substr(expression1,whereishi_t,1);
               put whereishi_t= whatfound=;
            end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following lines output to the log:

```
whereishi_t=2 whatfound=i
whereishi_t=5 whatfound=h
The End
```

Example 7: Searching for All Characters, Excluding h, i, H, and I

The following program searches for all of the characters in the string, excluding the characters h, i, H, and I. FINDC with the v modifier counts only the characters that do not appear in the characters argument. This example also includes the i modifier and therefore ignores character case during the search.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(14) xyz;
   dcl double whereishi_iv;
   method run();
      whereishi_iv=0;
      do until(whereishi_iv=0);
         xyz='Hi there, Ian!';
         whereishi_iv=findc(xyz,'hi',whereishi_iv+1,'iv');
         if whereishi_iv=0 then put 'The End';
         else do;
            whatfound=substr(xyz,whereishi_iv,1);
            put whereishi_iv= whatfound=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
whereishi_iv=3 whatfound=
whereishi_iv=4 whatfound=t
whereishi_iv=6 whatfound=e
whereishi_iv=7 whatfound=r
whereishi_iv=8 whatfound=e
whereishi_iv=9 whatfound=,
whereishi_iv=10 whatfound=
whereishi_iv=12 whatfound=a
whereishi_iv=13 whatfound=n
whereishi_iv=14 whatfound=!
The End
```

FINDW Function

Returns the character position of a word in a string, or returns the number of the word in a string.

Category: Character

Returned data type: DOUBLE

Syntax

FINDW(*string*, *word*[, *chars*])

FINDW(*string*, *word*, *chars*, *modifier(s)*[, *startpos*])

FINDW(*string*, *word*, *chars*, *startpos*[, *modifier(s)*])

FINDW(*string*, *word*, *startpos*[, *chars*[, *modifier(s)*]])

Required Arguments

string

is a character constant, variable, or expression that evaluates or can be coerced to a character string and that specifies the character string to be searched.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Tip: Enclose a literal string of characters in quotation marks.

word
is a character constant, variable, or expression that evaluates or can be coerced to a character string and that specifies the word to be searched.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip Enclose a literal string of characters in quotation marks.

chars
is an optional character constant, variable, or expression that initializes a list of characters. The characters in this list are the delimiters that separate words, provided that you do not specify the K modifier in the *modifier* argument. If you specify the K modifier, then all characters that are not in this list are delimiters. You can add more characters to this list by using other modifiers.

is an optional character constant, variable, or expression that initializes a list of characters.

The characters in this list are the delimiters that separate words, provided that you do not specify the K modifier in the *modifier* argument. If you specify the K modifier, then all characters that are not in this list are delimiters. You can add more characters to this list by using other modifiers.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip Enclose a literal string of characters in quotation marks.

startpos
is an optional numeric constant, variable, or expression that is a whole number that specifies the position at which the search should begin and the direction in which to search.

Data type DOUBLE

'modifier(s)'
specifies a character constant, variable, or expression in which each non-blank character modifies the action of the FINDW function. The following characters, in uppercase or lowercase, can be used as modifiers: A (adds alphabetic characters to the list), C (adds control characters), and D (adds digits). Additional modifiers are available. See *SAS DS2 Language Reference* for more information.

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the FINDW function.

You can use the following characters as modifiers:

blank
is ignored.

a or A
adds alphabetic characters to the list of characters.

b or B
searches from right to left, instead of from left to right, regardless of the sign of the *startpos* argument.

c or C
adds control characters to the list of characters.

d or D
adds digits to the list of characters.

e or E
counts the words that are scanned until the specified word is found, instead of determining the character position of the specified word in the string. Fragments of words are not counted.

f or F
adds an underscore and English letters (that is, the characters that can begin a SAS variable name using VALIDVARNAME=V7) to the list of characters.

g or G
adds graphic characters to the list of characters.

h or H
adds a horizontal tab to the list of characters.

i or I
ignores the case of the characters.

k or K
causes all character that are not in the list of characters to be treated as delimiters. If K is not specified, then all characters that are in the list of characters are treated as delimiters. The K and V modifiers perform the same function.

l or L
adds lowercase letters to the list of characters.

m or M
specifies that multiple consecutive delimiters, and delimiters at the beginning or end of the *string* argument, refer to words that have a length of zero.

n or N
adds digits, an underscore, and English letters (that is, the characters that can appear in a SAS variable name using VALIDVARNAME=V7) to the list of characters.

o or O
processes the *chars* and the *modifier* arguments only once, rather than every time the FINDW function is called. Using the O modifier in DS2 (excluding WHERE clauses) can make FINDW run faster when you call it in a loop where the *chars* and the *modifier* arguments do not change.

p or P
adds punctuation marks to the list of characters.

q or Q
ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of the *string* argument contains unmatched quotation marks, then scanning from left to right produces different words than scanning from right to left.

r or R
removes leading and trailing delimiters from the *word* argument.

s or S
adds space characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed) to the list of characters.

t or T
trims trailing blanks from the *string*, *word*, and *chars* arguments.

u or U
adds uppercase letters to the list of characters.

v or V
causes all character that are not in the list of characters to be treated as delimiters. If V is not specified, then all characters that are in the list of characters are treated as delimiters. The V and K modifiers perform the same function.

w or W
adds printable characters to the list of characters.

x or X
adds hexadecimal characters to the list of characters.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip If you use the *modifier* argument, then it must be positioned after the *chars* argument.

Details

Definition of "Delimiter"

"Delimiter" refers to any of several characters that are used to separate words. You can specify the delimiters by using the *chars* argument, the *modifier* argument, or both. If you specify the Q modifier, then the characters inside substrings that are enclosed in quotation marks are not treated as delimiters.

Definition of "Word"

"Word" refers to a substring that has both of the following characteristics:

- bounded on the left by a delimiter or the beginning of the string
- bounded on the right by a delimiter or the end of the string

Note: A word can contain delimiters. In this case, the FINDW function differs from the SCAN function, in which words are defined as not containing delimiters.

Searching for a String

If the FINDW function fails to find a substring that both matches the specified word and satisfies the definition of a word, then FINDW returns a value of 0.

If the FINDW function finds a substring that both matches the specified word and satisfies the definition of a word, the value that is returned by FINDW depends on whether the E modifier is specified:

- If you specify the E modifier, then FINDW returns the number of complete words that were scanned while searching for the specified word. If *startpos* specifies a position in the middle of a word, then that word is not counted.
- If you do not specify the E modifier, then FINDW returns the character position of the substring that is found.

If you specify the *startpos* argument, then the absolute value of *startpos* specifies the position at which to begin the search. The sign of *startpos* specifies the direction in which to search:

Value of *startpos*	**Action**
greater than 0	search begins at position *startpos* and proceeds to the right. If *startpos* is greater than the length of the string, then FINDW returns a value of 0.
less than 0	search begins at position –*startpos* and proceeds to the left. If *startpos* is less than the negative of the length of the string, then the search begins at the end of the string.
equal to 0	FINDW returns a value of 0.

If you do not specify the *startpos* argument or the B modifier, then FINDW searches from left to right starting at the beginning of the string. If you specify the B modifier, but do not use the *startpos* argument, then FINDW searches from right to left starting at the end of the string.

Using the FINDW Function in an ASCII Environment

If you use the FINDW function with only two arguments, here are the default delimiters.

- If your computer uses ASCII characters, then the default delimiters are as follows:

  blank ! $ % & ( ) * + , - . / ; < ^ |

Using Null Arguments

The FINDW function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.

Examples

Example 1: Searching a Character String for a Word

The following program searches a character string for the word “she”, and returns the position of the beginning of the word.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double whereisshe;
   method run();
      whereisshe=findw('She sells sea shells? Yes, she does.','she');
      put whereisshe=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
whereisshe=28
```

Example 2: Searching a Character String and Using the Chars and Startpos Arguments

The following program contains two occurrences of the word “rain.” Only the second occurrence is found by FINDW because the search begins in position 25. The *chars* argument specifies a space as the delimiter.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double result;
   method run();
      result = findw('At least 2.5 meters of rain falls in a rain
forest.',
         'rain', ' ', 25);
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=40
```

Example 3: Searching a Character String and Using the I Modifier and the Startpos Argument

The following program uses the I modifier and returns the position of the beginning of the word. The I modifier disregards case, and the *startpos* argument identifies the starting position from which to search.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double result;
   dcl char(75) string;
   method run();
      string='Artists from around the country display their art at
         an art festival.';
      result=findw(string, 'Art',' ', 'i', 10);
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=47
```

Example 4: Searching a Character String and Using the E Modifier

The following program uses the E modifier and returns the number of complete words that are scanned while searching for the word "art."

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double result;
   dcl char(75) string;
   method run();
      string='Artists from around the country display their art at
         an art festival.';
      result=findw(string,'art',' ','E');
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=8
```

Example 5: Searching a Character String and Using the E Modifier and the Startpos Argument

The following program uses the E modifier to count words in a character string. The word count begins at position 50 in the string. The result is 3 because "art" is the third word after the 50th character position.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double result;
   dcl char(75) string;
   method run();
      string='Artists from around the country display their art at
         an art festival.';
      result=findw(string, 'art',' ','E',50);
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=3
```

Example 6: Searching a Character String and Using Two Modifiers

The following program uses the I and the E modifiers to find a word in a string.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double result;
   dcl char(130) string;
   method run();
      string='The Great Himalayan National Park was created in 1984.
Because
         of its terrain and altitude, the park supports a diversity
         of wildlife and vegetation.';
      result=findw(string,'park',' ','I E');
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=5
```

Example 7: Searching a Character String and Using the R Modifier

The following program uses the R modifier to remove leading and trailing delimiters from a word.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double result;
   dcl char(75) string;
   dcl char word;
   method run();
      string='Artists from around the country display their art at
         an art festival.';
      word='  art  ';
      result=findw(string, word, ' ', 'R');
      put result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
result=47
```

FIPNAME Function

Converts two-digit FIPS codes to uppercase state names.

Category: State and ZIP code

Restriction: This function is not supported on the CAS server.

Returned data type: CHAR

Syntax

FIPNAME(*expression*)

Required Argument

expression
specifies a numeric constant, variable, or expression that represents a U.S. FIPS code.

Data type CHAR(), DOUBLE

Details

If the FIPNAME function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

The FIPNAME function converts a U.S. Federal Information Processing Standards (FIPS) code to the corresponding state or U.S. territory name in uppercase, returning a value of up to 20 characters.

Comparisons

The FIPNAME, FIPNAMEL, and FIPSTATE functions take the same argument but return different values.

- FIPNAME returns uppercase state names.
- FIPNAMEL returns mixed case state names.
- FIPSTATE returns a two-character state postal code (or worldwide GSA geographic code for U.S. territories) in uppercase.

Example

The following example shows the difference when using FIPNAME, FIPNAMEL, and FIPSTATE on the two-digit FIPS code for the state of North Carolina:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
 data _null_;
```

```
    method run();
    dcl char(15) state;
    dcl char(2) statecode;
    state=fipname(37);
    put state=;
    state=fipnamel(37);
    put state=;
    statecode=fipstate(37);
    put statecode=;
    end;
  enddata;
run;
quit;
```

These statements produce these results:

```
state=NORTH CAROLINA
state=North Carolina
statecode=NC
```

- “STNAMEL Function” on page 1172

FIPNAMEL Function

Converts two-digit FIPS codes to mixed case state names.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR

Syntax

FIPNAMEL(*expression*)

Required Argument

expression
specifies a numeric constant, variable, or expression that represents a U.S. FIPS code.

Data type CHAR(), DOUBLE

Details

If the FIPNAMEL function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

The FIPNAMEL function converts a U.S. Federal Information Processing Standards (FIPS) code to the corresponding state or U.S. territory name in mixed case, returning a value of up to 20 characters.

Comparisons

The FIPNAME and FIPNAMEL functions both take a two-digit FIPS code as an argument and return a state name. FIPNAME returns uppercase state names. FIPNAMEL returns mixed case state names.

Example

The following example shows the result of the FIPNAMEL function on the two-digit FIPS code for the state of North Carolina:

```
proc ds2;
   data _null_;
   method run();
   dcl char(15) state;
   state=fipnamel(37);
   put state=;
   end;
   enddata;
run;
quit;
```

These statements produce these results:

```
state=North Carolina
```

- “FIPSTATE Function” on page 658
- “STFIPS Function” on page 1169
- “STNAME Function” on page 1170
- “STNAMEL Function” on page 1172

FIPSTATE Function

Converts two-digit FIPS codes to two-character state postal codes.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR(2)

Syntax

FIPSTATE(*expression*)

Required Argument

expression
specifies a numeric constant, variable, or expression that represents a U.S. FIPS code.

Details

If the FIPSTATE function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

The FIPSTATE function converts a U.S. Federal Information Processing Standards (FIPS) code to a two-character state postal code (or worldwide GSA geographic code for U.S. territories) in uppercase.

Example

The following example shows the result of the FIPSTATE function on the two-digit FIPS code for the state of North Carolina:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
 data _null_;
   method run();
   dcl char(2) statecode;
   statecode=fipstate(37);
   put statecode=;
   end;
 enddata;
run;
quit;
```

These statements produce these results:

```
statecode=NC
```

FLOOR Function

Returns the largest integer less than or equal to a numeric value expression.

Category:	Truncation
Returned data type:	DECIMAL, DOUBLE, NUMERIC

Syntax

FLOOR(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DECIMAL, DOUBLE, NUMERIC

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If *expression* is within 1E-12 of an integer, the function returns that integer. If the result is a number that does not fit into the range of a DOUBLE, the FLOOR function fails.

If the argument is DECIMAL, the result is DECIMAL. Otherwise, the argument is converted to DOUBLE (if not so already), and the result is DOUBLE.

Comparisons

The FLOOR function fuzzes the results so that if the results are within 1E-12 of an integer, the FLOOR function returns that integer. The FLOORZ function uses zero fuzzing. Therefore, with the FLOORZ function, you might get unexpected results.

Examples

Example 1: FLOOR Function Example

The following program illustrates the FLOOR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=floor(1.95);
      put x;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log.

```
1
```

Example 2: FLOOR Function with Matrix Package Example

The following program illustrates the FLOOR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a[2, 2];
   dcl double c[2, 2];

   method run();
      dcl package matrix m;
      dcl package matrix r;
      dcl double i j;

      a := (1323.43, -.72, 3.38, 45);

      m=_new_ matrix(a, 2, 2);
      r=m.floor();
      r.toarray(c);

      do i=1 to 2;
         do j=1 to 2;
            put c[i, j];
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1323
0
3
45
```

See Also

Functions:

- “CEIL Function” on page 414
- “CEILZ Function” on page 416
- “FLOORZ Function” on page 662

FLOORZ Function

Returns the largest integer that is less than or equal to the argument, using zero fuzzing.

Category: Truncation

Returned data type: DOUBLE

Syntax

FLOORZ(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Comparisons

Unlike the FLOOR function, the FLOORZ function uses zero fuzzing. If the argument is within 1E-12 of an integer, the FLOOR function fuzzes the result to be equal to that integer. The FLOORZ function does not fuzz the result. Therefore, with the FLOORZ function, you might get unexpected results.

Example

The following program illustrates the FLOORZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b c d e f var1 var2 var6;
   method run();
      var1=2.1;
      a=floorz(var1);
      put a=;
```

```
        var2=-2.4;
        b=floorz(var2);
        put b=;

        c=floorz(-1.6);
        put c=;

        var6=(1.-1.e-13);
        d=floorz(1-1.e-13);
        put d=;

        e=floorz(763);
        put e=;

        f=floorz(-223.456);
        put f=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a=2
b=-3
c=-2
d=0
e=763
f=-224
```

FMTINFO Function

Returns information about a SAS format or informat.

Category: Special

Restriction: This function returns information about formats that are supplied by SAS. It cannot be used for user-defined formats that are created with the FORMAT procedure.

Syntax

FMTINFO('*format-name*', '*information-type*');

Required Arguments

'format-name'
specifies the name of a SAS format or informat.

Requirement *format-name* must be enclosed in single quotation marks.

information-type
specifies the type of information that is returned. The *format-information* can be one of the following values: 'DESC' (short description), 'MINW' (minimum width), and 'MAXW' (maximum width). Additional information types are available. See *SAS DS2 Language Reference* for additional information.

specifies the type of information that is returned. *format-information* can be one of the following values:

'CAT'
returns the function category.

See For a complete list, see "Function Categories" on page 248.

'TYPE'
returns whether the *format-name* is a format, an informat, or both.

'DESC'
returns a short description of the format or informat.

'MIND'
returns the minimum number of digits to the right of the decimal place in the format or informat.

'MAXD'
returns the maximum number of digits to the right of the decimal place in the format or informat.

'DEFD'
returns the default number of digits to the right of the decimal place in the format or informat.

'MINW'
returns the minimum width value of the format or informat.

'MAXW'
returns the maximum width value of the format or informat.

'DEFW'
returns the default width value of the format or informat.

Restriction You can specify only one *information-type* argument.

Requirement *information-type* must be enclosed in single quotation marks.

Details

The FMTINFO function returns information about a format or informat. You can return the following information about a format or informat's category: the type of language element, a description of the language element, and the minimum, maximum, and default decimal and width values.

You cannot specify multiple arguments with the FMTINFO function.

The FMTINFO function returns a character string for all data values, including the numeric value arguments MIND, MAXD, DEFD, MINW, MAXW, and DEFW.

Example

The following program returns information about the DATE format.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(30) fdesc fcat ftype;
   dcl double fmind fmaxd fdefd fminw fmaxw fdefw;
   method run();
      ftype=fmtinfo('date','type');
      fcat= fmtinfo('date','cat');
      fdesc= fmtinfo('date','desc');
      fmind= fmtinfo('date','mind');
      fmaxd= fmtinfo('date','maxd');
      fdefd= fmtinfo('date','defd');
      fminw= fmtinfo('date','minw');
      fmaxw= fmtinfo('date','maxw');
      fdefw= fmtinfo('date','defw');
      put ftype=;
      put fcat=;
      put fdesc= ;
      put fmind= ;
      put fmaxd= ;
      put fdefd= ;
      put fminw= ;
      put fmaxw= ;
      put fdefw= ;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
ftype=BOTH
fcat=date
fdesc=date value
fmind=0
fmaxd=8
fdefd=0
fminw=5
fmaxw=11
fdefw=7
```

FNONCT Function

Returns the value of the noncentrality parameter of an F distribution.

Category: Mathematical

Returned data type: DOUBLE

Syntax

FNONCT(*x*, *ndf*, *ddf*, *probability*)

Required Arguments

x
is a numeric random variable.

Range $x \geq 0$

Data type DOUBLE

ndf
is a numeric numerator degree of freedom parameter.

Range $ndf > 0$

Data type DOUBLE

ddf
is a numeric denominator degree of freedom parameter.

Range $ddf > 0$

Data type DOUBLE

probability
is a probability.

Range $0 < probability < 1$

Data type DOUBLE

Details

The FNONCT function returns the nonnegative noncentrality parameter from a noncentral *F* distribution whose parameters are *x*, *ndf*, *ddf*, and *nc*. If *probability* is greater than the probability from the central *F* distribution whose parameters are *x*, *ndf*, and *ddf*, a root to this problem does not exist. In this case a missing value is returned. A Newton-type algorithm is used to find a nonnegative root *nc* of the equation

$$P_f(x|ndf, ddf, nc) - prob = 0$$

The following relationship applies to the preceding equation:

$$P_f(x|ndf, ddf, nc) = \varepsilon^{\frac{-nc}{2}} \sum_{j=0}^{\infty} \frac{\left(\frac{nc}{2}\right)^j}{j!} I_{\frac{(ndf)x}{ddf+(ndf)x}}\left(\frac{ddf}{2} + j, \frac{ddf}{2}\right)$$

In the equation, *I* (. . .) is the probability from the beta distribution that is given by the following equation:

$$I_x(a,b) = \frac{}{\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}} \int_0^x t^{a-1}(1-t)^{b-1} dt$$

If the algorithm fails to converge to a fixed point, a missing value is returned.

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data work /overwrite=yes;
   dcl double x df ddf nc prob ncc;
   method init();
      x=2;
      df=4;
      ddf=5;
      do nc=1 to 3 by .5;
         prob=probf(x, df, ddf, nc);
         ncc=fnonct(x, df, ddf, prob);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=work;
```

```
run;
```

Output 7.9 *Output from the FNONCT Function*

The SAS System

Obs	x	df	ddf	nc	prob	ncc
1	2	4	5	1.0	0.69277	1.00000
2	2	4	5	1.5	0.65701	1.50000
3	2	4	5	2.0	0.62232	2.00000
4	2	4	5	2.5	0.58878	2.50000

FUZZ Function

Returns the nearest whole number if the argument is within 1E-12 of that number.

Category: Truncation

Returned data type: DOUBLE

Syntax

FUZZ(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The FUZZ function returns the nearest whole number if the expression is within 1E-12 of the number (that is, if the absolute difference between the whole number and argument is less than 1E-12). Otherwise, the expression is returned.

Example

The following programs illustrate the FUZZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/**** returns nearest whole number ******/
proc ds2;
data test (overwrite=yes);
   dcl double var1 x;
   method run();
      var1=5.9999999999999;
      x=put(fuzz(var1),16.14);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
6
```

```
/**** returns the original expression ******/
proc ds2;
data test (overwrite=yes);
   dcl double var1 x;
   method run();
      var1=5.99999999;
      x=put(fuzz(var1),16.14);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
5.99999999
```

GAMINV Function

Returns a quantile from the gamma distribution.

Category: Quantile

Returned data type: DOUBLE

Syntax

GAMINV(*p*, *a*)

Required Arguments

p

specifies any valid expression that evaluates to a numeric probability.

Range $0 \leq p < 1$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

a

specifies any valid expression that evaluates to a numeric shape parameter.

Range $a > 0$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The GAMINV function returns the p^{th} quantile from the gamma distribution, with shape parameter *a*. The probability that a row from a gamma distribution is less than or equal to the returned quantile is *p*.

Note: GAMINV is the inverse of the PROBGAM function.

Example

The following program illustrates the GAMINV function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
  dcl double x y;
  method run();
      x=gaminv(0.5, 9);
      y=gaminv(.1, 2.1);
      put x;
      put y;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
8.66895118437038
0.5841932368992
```

See Also

Functions:

- "PROBGAM Function" on page 1004

GAMMA Function

Returns the value of the gamma function.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

GAMMA(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Restriction Nonpositive integers are invalid.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The GAMMA function returns the integral, which is given by the following equation.

$$\text{GAMMA}(x) = \int_0^\infty t^{x-1} e^{-t}\, dt.$$

For positive integers, GAMMA(x) is (x − 1)!. This function is commonly denoted by $\Gamma(x)$.

Example

The following program illustrates the GAMMA function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=gamma(6);
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
120
```

GARKHCLPRC Function

Calculates call prices for European options on stocks, based on the Garman-Kohlhagen model.

Category: Financial

Returned data type: DOUBLE

Syntax

GARKHCLPRC(*E*, *t*, *S*, R_d, R_f, *sigma*)

Required Arguments

E

is a nonmissing, positive value that specifies the exercise price.

Requirement Specify *E* and *S* in the same units.

Data type DOUBLE

t

is a nonmissing value that specifies the time to maturity.

Data type DOUBLE

S

is a nonmissing, positive value that specifies the spot currency price.

Requirement Specify *S* and *E* in the same units.

Data type DOUBLE

R_d

is a nonmissing, positive fraction that specifies the risk-free domestic interest rate for period *t*.

Requirement Specify a value for R_d for the same time period as the unit of *t*.

Data type DOUBLE

R_f

is a nonmissing, positive fraction that specifies the risk-free foreign interest rate for period *t*.

Requirement Specify a value for R_f for the same time period as the unit of *t*.

Data type DOUBLE

sigma
is a nonmissing, positive fraction that specifies the volatility of the currency rate.

Requirement Specify a value for *sigma* for the same time period as the unit of *t*.

Data type DOUBLE

Details

The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. The function is based on the following relationship:

$$\text{CALL} = SN(d_1)\left(\varepsilon^{-R_f t}\right) - EN(d_2)\left(\varepsilon^{-R_d t}\right)$$

Arguments

S
specifies the spot currency price.

N
specifies the cumulative normal density function.

E
specifies the exercise price of the option.

t
specifies the time to expiration.

R_d
specifies the risk-free domestic interest rate for period *t*.

R_f
specifies the risk-free foreign interest rate for period *t*.

$$d_1 = \frac{\left(\ln\left(\frac{S}{E}\right) + \left(R_d - R_f + \frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$d_2 = d_1 - \sigma\sqrt{t}$$

The following arguments apply to the preceding equation:

σ
specifies the volatility of the underlying asset.

σ^2
specifies the variance of the rate of return.

For the special case of *t*=0, the following equation is true:

$$\text{CALL} = \max((S - E), 0)$$

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. These functions return a scalar value.

Example

The following program illustrates the GARKHCLPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b;
   method run();
      a=garkhclprc(40, .5, 38, .06, .04, .2);
      b=garkhclprc(19, .25, 20, .05, .03, .09);
      put a=;
      put b=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1.44942510595479
1.1304209447635
```

Functions:

- "GARKHPTPRC Function" on page 675

GARKHPTPRC Function

Calculates put prices for European options on stocks, based on the Garman-Kohlhagen model.

Category: Financial

Returned data type: DOUBLE

Syntax

GARKHPTPRC(*E*, *t*, *S*, R_d, R_f, *sigma*)

Required Arguments

E

is a nonmissing, positive value that specifies the exercise price.

Requirement Specify *E* and *S* in the same units.

Data type DOUBLE

t

is a nonmissing value that specifies the time to maturity, in years.

Data type DOUBLE

S

is a nonmissing, positive value that specifies the spot currency price.

Requirement Specify *S* and *E* in the same units.

Data type DOUBLE

R_d

is a nonmissing, positive fraction that specifies the risk-free domestic interest rate for period *t*.

Requirement Specify a value for R_d for the same time period as the unit of *t*.

Data type DOUBLE

R_f

is a nonmissing, positive fraction that specifies the risk-free foreign interest rate for period *t*.

Requirement Specify a value for R_t for the same time period as the unit of *t*.

Data type DOUBLE

sigma

is a nonmissing, positive fraction that specifies the volatility of the currency rate.

Data type DOUBLE

Details

The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. The function is based on the following relationship:

$$\text{PUT} = \text{CALL} - S\left(\varepsilon^{-R_f t}\right) + E\left(\varepsilon^{-R_d t}\right)$$

Arguments

S
specifies the spot currency price.

E
specifies the exercise price of the option.

t
specifies the time to expiration, in years.

R_d
specifies the risk-free domestic interest rate for period *t*.

R_f
specifies the risk-free foreign interest rate for period *t*.

$$d_1 = \frac{\left(\ln\left(\frac{S}{E}\right) + \left(R_d - R_f + \frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$d_2 = d_1 - \sigma\sqrt{t}$$

The following arguments apply to the preceding equation:

σ
specifies the volatility of the underlying asset.

σ^2
specifies the variance of the rate of return.

For the special case of *t*=0, the following equation is true:

$$\text{PUT} = \max((E - S), 0)$$

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The GARKHPTPRC function calculates the put prices for European options on stocks, based on the Garman-Kohlhagen model. The GARKHCLPRC function calculates the call prices for European options on stocks, based on the Garman-Kohlhagen model. These functions return a scalar value.

Example

The following program illustrates the GARKHPTPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method run();
      a=garkhptprc(50, .7, 55, .05, .04, .2);
      b=garkhptprc(32, .3, 33, .05, .03, .3);
      put a=;
      put b=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1.4050880944848
1.56473205137371
```

GCD Function

Returns the greatest common divisor for a set of integers.

Category:	Mathematical
Returned data type:	DOUBLE
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

GCD(*expression-1*, *expression-2* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement At least two arguments are required.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The GCD (greatest common divisor) function returns the greatest common divisor of one or more integers. For example, the greatest common divisor for 30 and 42 is 6. The greatest common divisor is also called the highest common factor.

Example

The following program illustrates the GCD function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y;
   method run();
      x=gcd(10, 15);
      y=gcd(36, 45);
      put x;
      put y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
5
9
```

See Also

Functions:

- "LCM Function" on page 813

GEODIST Function

Returns the geodetic distance between two latitude and longitude coordinates.

Category: Distance

Returned data type: DOUBLE

Syntax

GEODIST(*latitude-1*, *longitude-1*, *latitude-2*, *longitude-2* [,*options*])

Required Arguments

latitude

is a numeric constant, variable, or expression that specifies the coordinate of a given position north or south of the equator. Coordinates that are located north of the equator have positive values; coordinates that are located south of the equator have negative values.

Restriction: If the value is expressed in degrees, it must be between 90 and -90. If the value is expressed in radians, it must be between pi/2 and -pi/2.

Data type: DOUBLE

longitude

is a numeric constant, variable, or expression that specifies the coordinate of a given position east or west of the prime meridian, which runs through Greenwich, England. Coordinates that are located east of the prime meridian have positive values; coordinates that are located west of the prime meridian have negative values.

Restriction: If the value is expressed in degrees, it must be between 540 and -540. If the value is expressed in radians, it must be between 3*pi and -3*pi.

Data type: DOUBLE

Optional Argument

options

specifies a character constant that indicates how to describe the distance.

The following descriptors are supported:

M
specifies distance in miles.

K
specifies distance in kilometers. K is the default value for distance.

D
specifies that input values are expressed in degrees. D is the default for input values.

R
specifies that input values are expressed in radians.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

The GEODIST function computes the geodetic distance between any two arbitrary latitude and longitude coordinates. Input values can be expressed in degrees or in radians.

Examples

Example 1: Calculating the Geodetic Distance in Kilometers

The following program shows the geodetic distance in kilometers between Mobile, AL (latitude 30.68 N, longitude 88.25 W), and Asheville, NC (latitude 35.43 N, longitude 82.55 W). The program uses the default K option.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double distance;
   method run();
      distance=geodist(30.68, -88.25, 35.43, -82.55);
      put 'Distance= ' distance 'kilometers';
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Distance= 748.652914703183 kilometers
```

Example 2: Calculating the Geodetic Distance in Miles

The following program uses the M option to compute the geodetic distance in miles between Mobile, AL (latitude 30.68 N, longitude 88.25 W), and Asheville, NC (latitude 35.43 N, longitude 82.55 W).

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double distance;
   method run();
      distance=geodist(30.68, -88.25, 35.43, -82.55, 'M');
      put 'Distance = ' distance 'miles';
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Distance = 465.191354181072 miles
```

Example 3: Calculating the Geodetic Distance with Input Measured in Degrees

The following program uses latitude and longitude values that are expressed in degrees to compute the geodetic distance between two locations. Both the D and the M options are specified in the program.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double distance lat1 long1 lat2 long2;
   method run();
      lat1=35.2;
      long1=-78.1;
      lat2=37.6;
      long2=-79.8;
      Distance = geodist(lat1,long1,lat2,long2,'DM');
      put 'Distance= ' Distance 'miles';
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Distance= 190.683975083577 miles
```

Example 4: Calculating the Geodetic Distance with Input Measured in Radians

The following program uses latitude and longitude values that are expressed in radians to compute the geodetic distance between two locations. The program converts degrees to radians before executing the GEODIST function. Both the R and the M options are specified in this program.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double distance pi lat1 long1 lat2 long2;
   method run();
      lat1=35.2;
      long1=-78.1;
      lat2=37.6;
      long2=-79.8;
      pi = constant('pi');
      lat1 = (pi*lat1)/180;
      long1 = (pi*long1)/180;
      lat2 = (pi*lat2)/180;
      long2 = (pi*long2)/180;
      Distance = geodist(lat1,long1,lat2,long2,'RM');
      put 'Distance= ' Distance 'miles';
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Distance= 190.683975083578 miles
```

References

Vincenty, T. 1975. “Direct and Inverse Solutions of Geodesics on the Ellipsoid with Application of Nested Equations.” *Survey Review* 22: 99–93.

GEOMEAN Function

Returns the geometric mean.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

GEOMEAN(*expression* [, ...*expression*])

Required Argument

expression
is any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If any argument is zero, then the geometric mean is zero. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the geometric mean of the non-null or nonmissing values.

Let n be the number of arguments with non-null or nonmissing values, and let $x_1, x_2, \ldots, x_n$ be the values of those arguments. The geometric mean is the n^{th} root of the product of the values:

$$\sqrt[n]{(x_1 * x_2 * \ldots * x_n)}$$

Equivalently, the geometric mean is shown in this equation.

$$\exp\left(\frac{(\log(x_1) + \log(x_2) + \ldots + \log(x_n))}{n}\right)$$

Floating-point arithmetic often produces tiny numerical errors. Some computations that result in zero when exact arithmetic is used might result in a tiny nonzero value when floating-point arithmetic is used. Therefore, GEOMEAN fuzzes the values of arguments that are approximately zero. When the value of one argument is extremely small relative to the largest argument, the former argument is treated as zero. If you do not want SAS to fuzz the extremely small values, then use the GEOMEANZ function.

Comparisons

The MEAN function returns the arithmetic mean (average), and the HARMEAN function returns the harmonic mean, whereas the GEOMEAN function returns the geometric mean of the non-null or nonmissing values. Unlike GEOMEANZ, GEOMEAN fuzzes the values of the arguments that are approximately zero.

Example

The following program illustrates the GEOMEAN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x1 x2;
   method run();
      x1=geomean(1,2,4,4);
      x2=geomean(.,4,12,24);
      put x1=;
      put x2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x1=2.37841423000544
x2=10.4829655768355
```

GEOMEANZ Function

Returns the geometric mean, using zero fuzzing.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

GEOMEANZ(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If any argument is zero, then the geometric mean is zero. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the geometric mean of the non-null or nonmissing values.

Let n be the number of arguments with non-null or nonmissing values, and let $x_1, x_2, \ldots, x_n$ be the values of those arguments. The geometric mean is the n^{th} root of the product of the values:

$$\sqrt[n]{(x_1 * x_2 * \ldots * x_n)}$$

Equivalently, the geometric mean is shown in this equation.

$$\exp\left(\frac{(\log(x_1) + \log(x_2) + \ldots + \log(x_n))}{n}\right)$$

Comparisons

The MEAN function returns the arithmetic mean (average), and the HARMEAN function returns the harmonic mean, whereas the GEOMEANZ function returns the geometric mean of the non-null or nonmissing values. Unlike GEOMEAN, GEOMEANZ does not fuzz the values of the arguments that are approximately zero.

Example

The following program illustrates the GEOMEANZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x1 x2;
   method run();
      x1=geomeanz(1,2,4,4);
      x2=geomeanz(.,4,12,24);
      put x1=;
      put x2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x1=2.37841423000544
x2=10.4829655768355
```

GETTHREADERRORSTATUS Function

Gets the runtime error status of the current DS2 thread.

Category:	Error Checking
Returned data type:	INTEGER

Syntax

GETTHREADERRORSTATUS()

Without Arguments

The GETTHREADERRORSTATUS() function has no arguments.

Details

The GETTHREADERRORSTATUS() function queries an internal status variable that is updated each time a non-fatal runtime error or warning occurs in a thread and returns the status of the variable. By default, the error status return values are as follows:

0
: no error has occurred

1
: a non-fatal error has occurred

2
: a warning has occurred

By default, the internal variable detects programming errors, such as invalid parameter values and invalid data type conversions. If an error occurs before a warning in the same thread, the error value takes precedence over the warning.

When used with the SET statement, the function checks the error status for each row of the input data set and, when used in conjunction with the _N_ predefined variable, can be used to return the row number of the errors. The error status resets to 0 (zero) after each loop of the RUN method.

When used with the SETTHREADERRORSTATUS function and an IF statement, the GETTHREADERRORSTATUS function can be used to return custom error status values for user-specified conditions. The SETTHREADERRORSTATUS function enables you to define a custom error status value for the internal status variable and an optional user-specified message. The SETTHREADERRORSTATUS function can also be used to explicitly reset the internal error status variable to 0 (zero).

The function runs in the current thread of a single threaded, multithreaded, or partially threaded DS2 program. When run in a multi-threaded environment, the GETTHREADERRORSTATUS() function returns the error status value of a thread running a DS2 THREAD block or a DS2 DATA block. Each thread that is running a DS2 THREAD block or DS2 DATA block maintains a separate error status value. For example, when five threads are spawned by a SET FROM statement with THREADS=5, each of the five threads running the DS2 THREAD block maintain their own error status value. In addition, the thread running the DATA block also maintains its own error status value, resulting in six error status values being maintained for the DS2 program.

The GETTHREADERRORSTATUS function is useful for detecting errors when executing a method in a DATA, PACKAGE, or THREAD block.

Examples

Example 1: Using the GETTHREADERRORSTATUS Function in a Single-Threaded Environment

The following program illustrates how the GETTHREADERRORSTATUS function can be used with the SET statement. The FACT function is executed on the Height

column of the sashelp.class data set. The GETTHREADERRORSTATUS function identifies which rows from the 19-row data set report an error because they store a negative or decimal value.

```
data indata;
  set sashelp.class;
run;

proc ds2;
ds2_options msgorder=temporal;                          /* 1 */
data _null_;
  method run();
    set indata;
    fact(Height);                                       /* 2 */
    if (getThreadErrorStatus() ne 0) then
        put 'ERROR for row' _n_;                        /* 3 */
  end;
enddata;
run;
quit;
```

1 MSGORDER=TEMPORAL is specified in the DS2_OPTIONS statement to intersperse PUT statement messages with diagnostic messages in the SAS log.

2 The FACT function specifies to report an error when a negative or decimal value is found in the specified column.

3 The automatic _N_ variable is included in the user-defined error message that is specified in the PUT statement to print the row number of each row where an error occurred.

In the log, information about the errors is provided in message pairs. The first line of each pair is the system-generated log line number of the operation that resulted in the error and the error message that the function returned. The FACT function is located on line 91 of the log. The second line, defined by the PUT statement, identifies the location of the error in the 19-row input data set.

```

```

Example 2: Using the GETTHREADERRORSTATUS Function in a Threaded Program

This example creates a table named LARGENUMBERSET that contains 10,000 rows, in which each thousandth row contains a null value. The SETTHREADERRORSTATUS and GETTHREADERRORSTATUS functions are specified in a thread program with the IF statement to identify and omit rows that have a null value from a partial summation of the values. Then, the thread program is executed in two threads to create a final summation of the number values.

```
proc ds2;
    data largeNumberSet (overwrite=yes);                    /* 1 */
         dcl int row;
         method run();
            dcl int x;
            do x = 1 to 10000;
                if (mod(x, 1000) = 0) then row = NULL;
                else row = x;
                output;
            end;
        end;
    enddata;
    run;
quit;

proc ds2;                                                   /* 2 */
    thread processDataset / overwrite=yes;
```

```
        dcl int partial_sum;
        retain partial_sum;

        /* Set the partial sum to 0 */
        method init();
            partial_sum = 0;
        end;

        /* Start processing each row */
        method run();
            set largeNumberSet;
            if (missing(row) or null(row)) then
                do;
                    setThreadErrorStatus(4);                /* 3 */
                    put 'Row' _n_ 'on thread' _threadid_ 'was null';
                end;
            if (getThreadErrorStatus() = 0) then partial_sum =
partial_sum + row;
        end;

        method term();
            output;
        end;
    endthread;

    data _null_;                                            /* 4 */
        dcl bigint  summation;
        dcl thread  processDataset t;
        retain summation;

        /* Initialize summation to 0 */
        method init();
            summation = 0;
        end;

        method run();
            set from t threads=2;
            summation = summation + partial_sum;
        end;

        method term();
            put summation=;
        end;
    enddata;
run;
quit;
```

1 The DATA block creates the table, inserting a null value each thousandth row.

2 The THREAD block does the following:

- sets the table as the input data set
- specifies an IF statement that defines a custom error condition
- issues the SETTHREADERRORSTATUS function to set a custom error status value for every row that meets the error condition
- specifies to perform a partial sum calculation on rows that return no errors

3 The SETTHREADERRORSTATUS function assigns an error status value of 4. You can specify any error status value that you choose. The PUT statement includes the automatic variables _N_ and _THREADID_ to print the row number and thread ID of each omitted row in the user-specified error message.

4 The DATA block executes the thread program and calculates the SUMMATION= value.

Because the error status value specifies a custom error condition, the log includes the user-defined error messages only.

```
… [ snip] ...
Row 808 on thread 1 was null
Row 1000 on thread 2 was null
Row 2000 on thread 2 was null
Row 1808 on thread 1 was null
Row 3000 on thread 2 was null
Row 4000 on thread 2 was null
Row 5000 on thread 2 was null
Row 6000 on thread 2 was null
Row 7000 on thread 2 was null
Row 8000 on thread 2 was null
summation=49950000
```

Example 3: How Package Errors Affect GETTHREADERRORSTATUS Results

This example illustrates the results of the GETTHREADERRORSTATUS function when errors in a thread program and data program result from a package method.

```
proc ds2;
    package mypkg / inline;                                  /* 1 */
        method getFactorial(int x);
            fact(x);
        end;
    endpackage;

    thread mythread;                                         /* 2 */
        dcl double result;
        method run();
        dcl package mypkg p();
        dcl int status;
        p.getFactorial(-3);
        status = getThreadErrorStatus();
        put 'The error status was' status 'on thread' _threadid_
'after an error occurred in the PACKAGE.';
        end;
    endthread;

    data _null_;                                             /* 3 */
        dcl thread mythread t();

        method run();
          set from t threads=4;
        end;

        method term();
```

```
        dcl package mypkg m();
        dcl int status;
        m.getFactorial(-2);
        status = getThreadErrorStatus();
        put 'The error status was' status 'in the DATA block after an
error occurred in the PACKAGE.';
        end;
    enddata;
run;
quit;
```

1 Package MYPKG creates a method, GETFACTORIAL, that accepts an integer as input. The method reports an error when a negative or decimal value is found in a specified column.

2 A thread program named MYTHREAD is defined. The thread program does the following:

- declares a global variable named RESULT as DOUBLE
- instantiates package MYPKG as package variable P()
- declares local variable STATUS as an integer
- uses package variable P() to call the GETFACTORIAL method and specifies an input value of -3. The value -3 will cause an error to occur in the GETFACTORIAL method.
- uses an assignment statement to call the GETTHREADERRORSTATUS function and assign the results to the STATUS variable
- uses the PUT statement to log a message with the error status and the thread ID after an error occurs in the package

3 The data program does the following:

- declares thread MYTHREAD as T()
- sets thread program T as input and specifies to run it in four threads
- instantiates package MYPKG as M()
- declares a local variable named STATUS
- uses package variable M() to call the GETFACTORIAL method and specifies an input value of -2. The value -2 will cause an error to occur in the GETFACTORIAL method.
- uses an assignment statement to call the GETTHREADERRORSTATUS function and assign the results to the STATUS variable
- uses the PUT statement to log a message with the error status after an error occurs in the package

In the log, the custom error messages precede the system-generated ERROR messages. The system-generated ERROR messages identify line 83 as the location of the error. Line 83 is the log line number of the FACT function in the package definition.

```
… [ snip] ...
The error status was 1 on thread 1 after an error occurred in the PACKAGE.
The error status was 1 on thread 3 after an error occurred in the PACKAGE.
The error status was 1 on thread 2 after an error occurred in the PACKAGE.
The error status was 1 on thread 4 after an error occurred in the PACKAGE.
The error status was 1 in the DATA block after an error occurred in the PACKAGE.
NOTE: Created thread mythread in data set work.mythread.
ERROR: Line 83: Invalid argument to function fact.
ERROR: Line 83: Invalid argument to function fact.
ERROR: Line 83: Invalid argument to function fact.
ERROR: Line 83: Invalid argument to function fact.
ERROR: Line 83: Invalid argument to function fact.
NOTE: Execution succeeded. No rows affected.
113     quit;
```

HARMEAN Function

Returns the harmonic mean.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

HARMEAN(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If any argument is negative, then the result is a null or missing value. A message appears in the log that the negative argument is invalid. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the harmonic mean of the non-null or nonmissing values.

If any argument is zero, then the harmonic mean is zero. Otherwise, the harmonic mean is the reciprocal of the arithmetic mean of the reciprocals of the values.

Let n be the number of arguments with non-null or nonmissing values, and let $x_1, x_2, \ldots, x_n$ be the values of those arguments. The harmonic mean is shown in this equation.

$$\frac{n}{\frac{1}{x_1}+\frac{1}{x_2}+\ldots+\frac{1}{x_n}}$$

Floating-point arithmetic often produces tiny numerical errors. Some computations that result in zero when exact arithmetic is used might result in a tiny nonzero value when floating-point arithmetic is used. Therefore, HARMEAN fuzzes the values of arguments that are approximately zero. When the value of one argument is extremely small relative to the largest argument, the former argument is treated as zero. If you do not want SAS to fuzz the extremely small values, then use the HARMEANZ function.

Comparisons

The MEAN function returns the arithmetic mean (average), and the GEOMEAN function returns the geometric mean, whereas the HARMEAN function returns the harmonic mean of the non-null or nonmissing values. Unlike HARMEANZ, HARMEAN fuzzes the values of the arguments that are approximately zero.

Example

The following program illustrates the HARMEAN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x1 x2;
   method run();
      x1=harmean(1,2,4,4);
      x2=harmean(.,4,12,24);
```

```
        put x1=;
        put x2=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x1=2
x2=8
```

HARMEANZ Function

Returns the harmonic mean, using zero fuzzing.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

HARMEANZ(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

If any argument is negative, then the result is a null or value. A message appears in the log that the negative argument is invalid. If all the arguments are null or values, then the result is a null or value. Otherwise, the result is the harmonic mean of the non-null or nonmissing values.

If any argument is zero, then the harmonic mean is zero. Otherwise, the harmonic mean is the reciprocal of the arithmetic mean of the reciprocals of the values.

Let n be the number of arguments with non-null or nonmissing values, and let $x_1, x_2, \ldots, x_n$ be the values of those arguments. The harmonic mean is shown in this equation.

$$\frac{n}{\frac{1}{x_1}+\frac{1}{x_2}+\ldots+\frac{1}{x_n}}$$

Comparisons

The MEAN function returns the arithmetic mean (average), and the GEOMEAN function returns the geometric mean, whereas the HARMEANZ function returns the harmonic mean of the non-null or nonmissing values. Unlike HARMEAN, HARMEANZ does not fuzz the values of the arguments that are approximately zero.

Example

The following program illustrates the HARMEANZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x1 x2;
   method run();
      x1=harmeanz(1,2,4,4);
      x2=harmeanz(.,4,12,24);
      put x1= x2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x1=2 x2=8
```

- “MEAN Function” on page 859

HBOUND Function

Returns the upper bound of an array.

Category: Array

Returned data type: INTEGER

Syntax

HBOUND(*array-name*[, *bound-n*])

Required Argument

array-name
specifies the name of a temporary or a variable array.

Data type CHAR

Optional Argument

bound-n
is a numeric constant, variable, or expression that specifies the dimension, in a multidimensional array, for which you want to know the upper bound. If no *bound-n* value is specified, the HBOUND function returns the upper bound of the first dimension of the array.

Bound-n evaluates to an integral value.

Data type INTEGER

Details

The HBOUND function returns the upper bound of a one-dimensional array, or the upper bound of a specified dimension of a multidimensional array.

HBOUND and LBOUND can be used together to return the values of the upper and lower bounds of an array dimension.

If the HBOUND function is called with a dimension value that is outside the dimension of the array, then a run-time error occurs and the function returns a NULL integer value.

Comparisons

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
- LBOUND returns the value of the lower bound of an array dimension.
- NDIMS returns the number of dimensions in an array.

Example

The following program shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(15) a1[4];
   dcl double a2[2,3,4] sum;
   method init();
      declare char(15) a1[4];
      declare double   a2[2,3,4] sum;
      a1 := ('red' 'yellow' 'green' 'blue');
      a2 := (24*2.0);
      do i = 1 to dim(a1);
         put a1[i];
      end;
      numelems = 0;
      do i = 1 to ndims(a2);
         numelems = numelems + dim(a2, i);
      end;
      sum = 0;
      do i = lbound(a2, 1) to hbound(a2, 1);
         do j = lbound(a2, 2) to hbound(a2, 2);
            do k = lbound(a2, 3) to hbound(a2, 3);
               sum = sum + a2[i,j,k];
            end;
```

```
            end;
         end;
         put sum=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log:

```
red
yellow
green
blue
sum=48
```

- “NDIMS Function” on page 878

HMS Function

Returns a SAS time value from hour, minute, and second values.

Category: Date and Time

Returned data type: DOUBLE

Syntax

HMS(*hour*, *minute*, *second*)

Required Arguments

hour
a numeric expression.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

minute
a numeric expression.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

second
a numeric expression.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The HMS function returns a numeric value that represents a SAS time value. A SAS time value is a number that represents the number of seconds since midnight of the current day.

Example

The following program illustrates the HMS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a;
   dcl varchar(10) b;
   method run();
      a=hms(12,45,10);
      b=put(a, time.);
      put a;
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
45910
12:45:10
```

HOLIDAY Function

Returns a SAS date value of a specified holiday for a specified year.

Category: Date and Time

Returned data type: DOUBLE

Syntax

HOLIDAY('*holiday*', *year*)

Required Arguments

'holiday'

is a character constant, variable, or expression that specifies one of the following values: BOXING, CANADA, CANADAOBSERVED, CHRISTMAS, COLUMBUS, EASTER, FATHERS, HALLOWEEN, LABOR, MLK, MEMORIAL, MOTHERS, NEWYEAR, THANKSGIVING, THANKSGIVINGCANADA, USINDEPENDENCE, USPRESIDENTS, VALENTINES, VETERANS, VETERANSUSG, VETERANSUSPS, and VICTORIA. Values for *holiday* can be in uppercase or lowercase. For additional information, see *SAS DS2 Language Reference*.

is a character constant, variable, or expression that specifies one of the values listed in the following table.

Values for *holiday* can be in uppercase or lowercase.

Table 7.3 *Holiday Values and Their Descriptions*

Holiday Value	Description	Date Celebrated
BOXING	Boxing Day	December 26
CANADA	Canadian Independence Day	July 1
CANADAOBSERVED	Canadian Independence Day observed	July 1, or July 2 if July 1 is a Sunday
CHRISTMAS	Christmas	December 25
COLUMBUS	Columbus Day	2nd Monday in October
EASTER	Easter Sunday	date varies
FATHERS	Father's Day	3rd Sunday in June
HALLOWEEN	Halloween	October 31
LABOR	Labor Day	1st Monday in September
MLK	Martin Luther King, Jr. 's birthday	3rd Monday in January beginning in 1986
MEMORIAL	Memorial Day	last Monday in May (since 1971)
MOTHERS	Mother's Day	2nd Sunday in May
NEWYEAR	New Year's Day	January 1
THANKSGIVING	U.S. Thanksgiving Day	4th Thursday in November
THANKSGIVINGCANADA	Canadian Thanksgiving Day	2nd Monday in October
USINDEPENDENCE	U.S. Independence Day	July 4
USPRESIDENTS	Abraham Lincoln's and George Washington's birthdays observed	3rd Monday in February (since 1971)
VALENTINES	Valentine's Day	February 14

Holiday Value	Description	Date Celebrated
VETERANS	Veterans Day	November 11
VETERANSUSG	Veterans Day - U.S. government-observed	U.S. government-observed date for Monday–Friday schedule
VETERANSUSPS	Veterans Day - U.S. post office observed	U.S. government-observed date for Monday–Saturday schedule (U.S. Post Office)
VICTORIA	Victoria Day	Monday on or preceding May 24

Data type CHAR

year
is a numeric constant, variable, or expression that specifies a four-digit year. If you use a two-digit year, then you must specify the YEARCUTOFF= system option.

Data type DOUBLE

Details

The HOLIDAY function computes the date on which a specific holiday occurs in a specified year. Only certain common U.S. and Canadian holidays are defined for use with this function. (See "Holiday Values and Their Descriptions" in *SAS Functions and CALL Routines: Reference* for a list of valid holidays.)

The definition of many holidays has changed over the years. In the U.S., Executive Order 11582, issued on February 11, 1971, fixed the observance of many U.S. federal holidays.

The current holiday definition is extended indefinitely into the past and future, although many holidays have a fixed date at which they were established. Some holidays have not had a consistent definition in the past.

The HOLIDAY function returns a SAS date value. To convert the SAS date value to a calendar date, use any valid SAS date format, such as the DATE9. format.

Comparisons

In some cases, the HOLIDAY function and the NWKDOM function return the same result. For example, the statement `holiday('thanksgiving', 2012);` returns the same value as `nwkdom(4, 5, 11, 2012);`.

In other cases, the HOLIDAY function and the MDY function return the same result. For example, the statement `holiday('christmas', 2012);` returns the same value as `mdy(12, 25, 2012);`.

Example

The following programs illustrate the HOLIDAY function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/*** Thanksgiving ***/

proc ds2;
data _null_;
   dcl double thanks having format date9.;
   method init();
      thanks = holiday('thanksgiving', 2019);
      put thanks;
   end;
enddata;
run;

/*** Boxing ***/
data _null_;
   method run();
      dcl double boxing having format date9.;
      boxing = holiday('boxing', 2019);
      put boxing;
   end;
enddata;
run;

/*** Easter ***/
data _null_;
   method run();
      dcl double easter having format date9.;
      easter = holiday('easter', 2019);
      put easter;
   end;
enddata;
run;

/*** Canada Day ***/
data _null_;
   method run();
      dcl double canada having format date9.;
```

```
      canada = holiday('canada', 2019);
      put canada;
   end;
enddata;
run;

/*** Father's Day ***/
data _null_;
   method run();
     dcl double fathers having format date9.;
      fathers = holiday('fathers', 2019);
      put fathers;
   end;
enddata;
run;

/*** Valentine's Day ***/
data _null_;
   method run();
      dcl double valentines having format date9.;
      valentines = holiday('valentines', 2019);
      put valentines;
   end;
enddata;
run;

/*** Victoria Day ***/
data _null_;
   method run();
      dcl double victoria having format date9.;
      victoria = holiday('victoria', 2019);
      put victoria;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
28NOV2019

26DEC2019

21APR2019

01JUL2019

16JUN2019

14FEB2019

20MAY2019
```

See Also

Functions:

- “MDY Function” on page 857
- “NWKDOM Function” on page 923

HOUR Function

Returns the hour from a SAS time or datetime value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

HOUR(*time* | *datetime*)

Required Arguments

time
specifies any valid expression that represents a SAS time value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

datetime
specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The HOUR function returns a numeric value that represents the hour from a SAS time or datetime value. Numeric values can range from 0 through 23. HOUR always returns a positive number.

Example

The following program illustrates the HOUR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a;
   method run();
      a=hour(time());
      put a=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
14
```

See Also

- "Dates and Times in DS2" in *SAS DS2 Programmer's Guide*

Functions:

- "MINUTE Function" on page 863
- "SECOND Function" on page 1139

IBESSEL Function

Returns the value of the modified Bessel function.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

IBESSEL(*nu*, *x*, *kode*)

Required Arguments

nu

specifies a numeric constant, variable, or expression.

Range *nu* ≥ 0

Data type DOUBLE

x

specifies a numeric constant, variable, or expression.

Range *x* ≥ 0

Data type DOUBLE

kode

is a numeric constant, variable, or expression that specifies a nonnegative whole number.

Data type DOUBLE

Details

The IBESSEL function returns the value of the modified Bessel function of order *nu* evaluated at *x* (Abramowitz, Stegun 1964; Amos, Daniel, Weston 1977). When *kode* equals 0, the Bessel function is returned. Otherwise, the value of the following function is returned:

$$\varepsilon^{-x} I_{nu}(x)$$

Example

The following program illustrates the IBESSEL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=ibessel(2, 2, 0);
      put x=;
      x=ibessel(2, 2, 1);
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=0.68894844769873
x=0.09323903330473
```

Functions:

- "JBESSEL Function" on page 798

IFN_164 Function

Returns a numeric value based on whether an expression is true, false, or missing.

Categories: Mathematical
CAS

Notes: Beginning in 2025.12 this function supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure BIGINIT functionality. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

IFN_I64 supports BIGINT arguments and returns a BIGINT result.

Syntax

IFN_164(*logical-expression*, *value-returned-when-true*, *value-returned-when-false* [, *value-returned-when-missing*])

Required Arguments

logical-expression
specifies a numeric constant, variable, or expression.

value-returned-when-true
specifies a numeric constant, variable, or expression that is returned when the value of *logical-expression* is true.

value-returned-when-false
specifies a numeric constant, variable, or expression that is returned when the value of *logical-expression* is false.

Optional Argument

value-returned-when-missing
specifies a numeric constant, variable or expression that is returned when the value of *logical-expression* is missing.

Details

The IFN_164 function uses conditional logic that enables you to select among several values based on the value of a logical expression.

IFN_164 evaluates the first argument, then *logical-expression*. If *logical-expression* is true (that is, not zero and not missing), then IFN_164 returns the value in the second argument. If *logical-expression* is a missing value, and you have a fourth argument, then IFN_164 returns the value in the fourth argument. Otherwise, if *logical-expression* is false, IFN_164 returns the value in the third argument.

The IFN_164 function, an IF/THEN/ELSE construct, or a WHERE statement can produce the same results. (See examples.) However, the IFN_164 function is useful in DATA step expressions when it is not convenient or possible to use an IF/THEN/ELSE construct or a WHERE statement.

Comparisons

The IFN_164 function is similar to the IFC function, except that IFN_164 returns a numeric value whereas IFC returns a character value.

Examples

Example 1: Calculating Commission Using the IFN Function

In the following example, IFN_164 evaluates the expression `TotalSales > 10000`. If total sales exceeds $10,000, then the sales commission is 5% of the total sales. If total sales is less than $10,000, then the sales commission is 2% of the total sales.

```
data _null_;
   input TotalSales;
   commission=ifn_164(TotalSales > 10000, TotalSales*.05,
TotalSales*.02);
   put commission=;
   datalines;
25000
10000
500
10300
;
```

SAS writes the following output to the log:

```
commission=1250
commission=200
commission=10
commission=515
```

Example 2: Calculating Commission Using an IF/THEN/ELSE Construct

In the following example, an IF/THEN/ELSE construct evaluates the expression `TotalSales > 10000`. If total sales exceeds $10,000, then the sales commission is 5% of the total sales. If total sales is less than $10,000, then the sales commission is 2% of the total sales.

```
data _null_;
   input TotalSales;
   if TotalSales > 10000 then commission = .05 * TotalSales;
      else commission = .02 * TotalSales;
   put commission=;
   datalines;
25000
10000
500
10300
;
```

SAS writes the following output to the log:

```
commission=1250
commission=200
commission=10
commission=515
```

Example 3: Calculating Commission Using a WHERE Statement

In the following example, a WHERE statement evaluates the expression `TotalSales > 10000`. If total sales exceeds $10,000, then the sales commission is 5% of the total sales. If total sales is less than $10,000, then the sales commission is 2% of the total sales. The output shows only those salespeople whose total sales exceed $10,000.

```
data sales;
   input SalesPerson $ TotalSales;
   datalines;
Michaels 25000
Janowski 10000
Chen 500
Gupta 10300
;
data commission;
   set sales;
   where TotalSales > 10000;
   commission = TotalSales * .05;
run;
proc print data=commission;
   title 'Commission for Total Sales > 1000';
run;
```

Output 7.10 *Output from a WHERE Statement*

Commission for Total Sales > 1000

Obs	SalesPerson	TotalSales	commission
1	Michaels	25000	1250
2	Gupta	10300	515

See Also

Functions:

- "IFC Function" in *SAS Functions and CALL Routines: Reference*

INDEX Function

Searches a character expression for a string of characters, and returns the position of the string's first character for the first occurrence of the string.

Category: Character

Returned data type: INTEGER

Syntax

INDEX(*target-expression*, *search-expression*)

Required Arguments

target-expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

search-expression
specifies any valid expression that evaluates or can be coerced to a character string that is used to search for in *target-expression*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip Enclose a literal string of characters in single quotation marks.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The INDEX function searches *target-expression*, from left to right, for the first occurrence of the string specified in *search-expression*, and returns the position in *target-expression* of the string's first character. If the string is not found in *target-expression*, INDEX returns a value of 0. If there are multiple occurrences of the string, INDEX returns only the position of the first occurrence.

Note: When either the *target-expression* or the *search-expression* has a length of 0, the INDEX function returns a value of 0. It should also be noted that an undeclared VARCHAR variable has a length of 0.

Comparisons

The VERIFY function returns the position of the first character in *target-expression* that does not contain *search-expression* where the INDEX function returns the position of the first occurrence of *search-expression* that is present in *target-expression*.

Example

The following program illustrates the INDEX statement:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double c;
   dcl varchar(20) a b;
   method run();
      a='ABC.DEF (X=Y)';
      b='X=Y';
      c=index(a,b);
      put c=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
c=10
```

See Also

Functions:

- “INDEXC Function” on page 715
- “INDEXW Function” on page 717
- “VERIFY Function” on page 1246

INDEXC Function

Searches a character expression for specified characters and returns the position of the first occurrence of any of the characters.

Category: Character

Returned data type: DOUBLE

Syntax

INDEXC(*target-expression*, *search-expression*[, ...*search-expression*])

Required Arguments

target-expression
specifies any valid expression that evaluates or can be coerced to a character string that is searched.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

search-expression
specifies the characters to search for in *target-expression*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip Enclose a literal string of characters in single quotation marks.

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The INDEXC function searches *target-expression* for the first occurrence of any character present in the search expressions and returns the position in *target-expression* of that character. The search is performed from left to right. If none of the characters in the search expressions are found in *target-expression*, INDEXC returns a value of 0.

Comparisons

The INDEXC function searches for the first occurrence of any individual character that is present within the search expression, whereas the INDEX function searches for the first occurrence of the search expression as a pattern.

Example

The following program illustrates the INDEXC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   dcl varchar(20) a b c;
   method run();
      a='ABC.DEP (X2=Y1)';
      b='()';
      c='=.';
      x=indexc(a,'0123',';()=.');
      put x=;
      x=indexc(a,b);
      put x=;
      x=indexc(a,b,c);
      put x=;
      c='have a good day';
      x=indexc(c,'pleasant','very');
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=4
x=9
x=4
x=2
```

See Also

Functions:

- “INDEX Function” on page 713
- “INDEXW Function” on page 717

INDEXW Function

Searches a character expression for a string that is specified as a word, and returns the position of the first character in the word.

Category: Character

Returned data type: DOUBLE

Syntax

INDEXW(*target-expression*, *search-expression* [, *delimiter*])

Required Arguments

target-expression
specifies any valid expression that evaluates or can be coerced to a character string and that is searched.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

search-expression
specifies any valid expression that evaluates or can be coerced to a character string and that is searched for in *target-expression*. SAS removes the leading and trailing delimiters from *search-expression*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Optional Argument

delimiter
specifies a character expression that you want INDEXW to use as a word separator in the character strings. The default delimiter is the blank character.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip If the blank character is a delimiter, order it so that it is not the last character in *delimiter*. Trailing blanks are ignored because *delimiter* is trimmed of trailing blanks.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The INDEXW function searches *target-expression*, from left to right, for the first occurrence of *search-expression* and returns the position in *target-expression* of the substring's first character. If the substring is not found in *target-expression*, then INDEXW returns a value of 0. If there are multiple occurrences of the string, then INDEXW returns only the position of the first occurrence.

The substring pattern must begin and end on a word boundary. For INDEXW, word boundaries are delimiters, the beginning of *target-expression*, and the end of *target-expression*.

TIP INDEXW has the following behavior when *search-expression* contains blank spaces or has a length of 0:

- If both *target-expression* and *search-expression* contain only blank spaces or have a length of 0, then INDEXW returns a value of 1.
- If *search-expression* contains only blank spaces or has a length of 0, and *target-expression* contains character or numeric data, then INDEXW returns a value of 0.

Comparisons

The INDEXW function searches for strings that are words, whereas the INDEX function searches for patterns as separate words or as parts of other words. INDEXC searches for any characters that are present in the excerpts.

Example

The following program illustrates the INDEXW function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double c b;
   dcl varchar(20) a word x xyz;
```

```
      method run();
         a='The power to know.';
         word='power';
         c=indexw(a,word);
         put c=;
         a='The power to know.';
         b=indexw(a,'know');
         put b=;
         a='The power to know.';
         b=indexw(a,'know','. ');
         put b=;
         a='abc,def@ xyz';
         b=indexw(a,',', '@');
         put b=;
         a='abc,def@ xyz';
         b=indexw(a,'def', '@,');
         put b=;
         x='abc,def@ xyz';
         xyz=indexw(x, ' xyz', '@');
         put xyz=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log.

```
c=5
b=0
b=14
b=0
b=5
xyz=9
```

Functions:

- “INDEX Function” on page 713
- “INDEXC Function” on page 715

INPUTC Function

Enables you to specify a character informat at run time.

Category:	Special
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INPUTC(*source*, *informat*[, *w*])

Required Arguments

source
specifies a character constant, variable, or expression to which you want to apply the informat.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

informat
is a character constant, variable, or expression that contains the character informat that you want to apply to *source*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Optional Argument

w
specifies any valid expression that evaluates to a numeric width to apply to the informat.

Interaction If you specify a width here, it overrides any width specification in the informat.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If the INPUTC function returns a value to a variable that has not yet been assigned a length, by default the variable length is determined by the length of the first argument.

Comparisons

The INPUTN function enables you to specify a numeric informat at run time.

Example

The following program illustrates how to specify character informats.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(10) type type2;
   method init();
      type=inputc('positive', '$upcase15.');
      type2=inputc('positive', '$upcase15.', 3);
      put type=;
      put type2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
type=POSITIVE
type2=POS
```

See Also

Functions:

- "INPUTN Function" on page 721
- "PUT Function" on page 1051

INPUTN Function

Enables you to specify a numeric informat at run time.

Category: Special

Returned data type: DOUBLE

Syntax

INPUTN(*source*, *informat*[, *w*[, *d*]])

Required Arguments

source
specifies a character constant, variable, or expression to which you want to apply the informat.

Data type CHAR

informat
is a character constant, variable, or expression that contains the numeric informat that you want to apply to *source*.

Data type CHAR

Optional Arguments

w
is a numeric constant, variable, or expression that specifies a width to apply to the informat.

Interaction If you specify a width here, it overrides any width specification in the informat.

Data type DOUBLE

d
is a numeric constant, variable, or expression that specifies the number of decimal places to use.

Interaction If you specify a number here, it overrides any decimal-place specification in the informat.

Data type DOUBLE

Comparisons

The INPUTC function enables you to specify a character informat at run time. Using the PUT function is faster because you specify the informat at compile time.

Example

The following program illustrates how to specify numeric informats.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method init();
      declare double salary;
      salary = inputn('20,000.00', 'comma10.2');
      put salary=;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
20000
```

- “PUT Function” on page 1051

INPUTN_164 Function

Specifies a numeric informat at run time.

Category: Special

Returned data type: DOUBLE

Notes: Beginning in 2025.12 this function supports the BIGINT data type when run in the DS2 language. Set BIGINTPROCESSING=YES to ensure BIGINIT functionality. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

INPUTN_I64 returns a BIGINT result.

Syntax

INPUTN_164(*source*, *informat*[, *w*[, *d*]])

Required Arguments

source

specifies a character constant, variable, or expression to which you want to apply the informat.

Data type CHAR

informat

is a character constant, variable, or expression that contains the numeric informat that you want to apply to *source*.

Data type CHAR

Optional Arguments

w

is a numeric constant, variable, or expression that specifies a width to apply to the informat.

Interaction: If you specify a width here, it overrides any width specification in the informat.

Data type: DOUBLE

d

is a numeric constant, variable, or expression that specifies the number of decimal places to use.

Interaction: If you specify a number here, it overrides any decimal-place specification in the informat.

Data type: DOUBLE

Comparisons

The INPUTN_I64 function enables you to specify a character informat at run time. Using the PUT function is faster because you specify the informat at compile time.

Example

The following program illustrates how to specify numeric informats.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method init();
      declare double salary;
      salary = INPUTN_164('20,000.00', 'comma10.2');
      put salary=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
20000
```

- “PUT Function” on page 1051

INT Function

Returns the whole number, fuzzed to avoid unexpected floating-point results.

Category: Truncation

Returned data type: DOUBLE

Syntax

INT(*expression*)

Required Argument

expression
specifies any expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The INT function returns the whole number portion of the argument (truncates the decimal portion). If the argument’s value is within 1E-12 of a whole number, the function results in that whole number. If the value of *expression* is positive, the INT function has the same result as the FLOOR function. If the value of *expression* is negative, the INT function has the same result as the CEIL function.

Comparisons

Unlike the INTZ function, the INT function fuzzes the result. If the argument is within 1E-12 of a whole number, the INT function fuzzes the result to be equal to

that whole number. The INTZ function does not fuzz the result. Therefore, with the INTZ function, you might get unexpected results.

Example

The following program illustrates the INT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double var1 a b c d;
   method run();
      var1=2.1;
      a=int(var1);
      put a;
      b=int(-2.4);
      put b;
      c=int(1+1.e-11);
      put c;
      d=int(-1.6);
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2
-2
1
-1
```

- “ROUND Function” on page 1101

INTCINDEX Function

Returns the cycle index when a date, time, or timestamp interval and value are specified.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTCINDEX({*interval*[*multiple*][.*shift-index*]}, *date-time-value*)

Required Arguments

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip *Interval* can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

date-time-value
specifies a date, time, or timestamp value that represents a time period of a specified interval.

Data type DOUBLE

Optional Arguments

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Details

The Basics

The INTCINDEX function returns the index of the seasonal cycle when you specify an interval and a DATE, TIME, or TIMESTAMP value. For example, if the interval is MONTH, each observation in the data corresponds to a particular month. Monthly data is considered to be periodic for a one-year period. A year contains 12 months, so the number of intervals (months) in a seasonal cycle (year) is 12. WEEK is the seasonal cycle for an interval that is equal to DAY. This example returns a value of 36 because September 1, 2013, is the sixth day of the 35th week of the year.

```
sasdate1=to_double(date'2013-09-01');
cycle_index1 = intcindex('day', sasdate1);
```

For more information about working with date and time intervals, see "Date and Time Intervals" in *SAS Functions and CALL Routines: Reference*.

The INTCINDEX function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For a list of these intervals, see

"Retail Calendar Intervals: ISO 8601 Compliant" in *SAS Programmer's Guide: Essentials*.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][*.shift-index*]

For more information, see "Required Arguments" on page 727.

Comparisons

The INTCINDEX function returns the cycle index, whereas the INTINDEX function returns the seasonal index.

In this example, the INTCINDEX function returns the week of the year.

```
sasdate1=to_double(date'04apr2013');
cycle_index = intcindex('day', sasdate1);
```

In this example, the INTINDEX function returns the day of the week.

```
sasdate1=to_double(date'04apr2013');
index = intindex('day','04APR2013'd);
```

In this example, the INTCINDEX function returns the hour of the day.

```
sasts=to_double(timestamp '2012-09-01 00:00:00');
a= intcindex('minute', sasts);
```

In this example, the INTINDEX function returns the minute of the hour.

```
sasts=to_double(timestamp'2012-09-01 00:00:00');
a= intindex('minute', sasts);
```

In the example `intseas(intcycle('interval'));`, the INTSEAS function returns the maximum number that could be returned by `intcindex('interval', date);`.

Example

The following programs illustrate the INTCINDEX function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 cycle_index1;
   method run();
```

```
      sasdate1=as_double(date'2013-09-01');
      cycle_index1 = intcindex('day', sasdate1);
      put cycle_index1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
36
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sascydate cycle_index1;
   method run();
      sascydate=as_double(timestamp '2013-05-23 05:03:01');
      cycle_index1 = intcindex('dtqtr', sascydate);
      put cycle_index1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sascydate cycle_index1;
   method run();
      sascydate=as_double(date'2013-12-13');
      cycle_index1 = intcindex('tenday', sascydate);
      put cycle_index1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sascydate cycle_index1;
   method run();
      sascydate=as_double(time '23:13:02');
      cycle_index1 = intcindex('minute', sascydate);
      put cycle_index1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
24
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sascydate cycle_index1;
   dcl char(10) var1;
   method run();
      sascydate=as_double(timestamp '2013-05-05 10:54:03');
      var1='semimonth';
      cycle_index1 = intcindex(var1, sascydate);
      put cycle_index1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
```

- “INTINDEX Function” on page 754
- “INTSEAS Function” on page 777

INTCK Function

Returns the number of interval boundaries of a given kind that lie between two SAS dates, times, or timestamp values encoded as DOUBLE.

Category:	Date and Time
Restriction:	DS2 does not support custom date or time intervals.
Returned data type:	DOUBLE

Syntax

INTCK({*interval*[*multiple*][.*shift-index*]}, *start-date*, *end-date*[, '*method*'])

INTCK(*start-date*, *end-date*[, '*method*'])

Required Arguments

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip *Interval* can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

start-date
specifies an expression that represents the starting SAS date, time, or timestamp value.

Data type DOUBLE

end-date
specifies an expression that represents the ending SAS date, time, or timestamp value.

Data type DOUBLE

Optional Arguments

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the

shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

'method'

specifies that intervals are counted using either a discrete or a continuous method. Enclose *method* in quotation marks. *Method* can be one of these values: CONTINUOUS and DISCRETE (counts interval boundaries).

specifies that intervals are counted using either a discrete or a continuous method.

You must enclose *method* in quotation marks. *Method* can be one of these values:

CONTINUOUS

specifies that continuous time is measured. The interval is shifted based on the starting date.

For example, the distance in months between January 15, 2013, and February 15, 2013, is one month.

Alias C or CONT

DISCRETE

specifies that discrete time is measured. The discrete method counts interval boundaries (for example, end of month).

The default discrete method is useful to sort time series observations into bins for processing. For example, daily data can be accumulated to monthly data for processing as a monthly series.

For the DISCRETE method, the distance in months between January 31, 2013, and February 1, 2013, is one month.

Alias D or DISC

Default DISCRETE

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][*.shift-index*]

For more information, see "Required Arguments" on page 732.

Calendar Interval Calculations

All values within a discrete time interval are interpreted as being equivalent. This means that the dates of January 1, 2013 and January 15, 2013 are equivalent when you specify a monthly interval. Both of these dates represent the interval that begins on January 1, 2013 and ends on January 31, 2013. You can use the date for the beginning of the interval (January 1, 2013) or the date for the end of the interval (January 31, 2013) to identify the interval. These dates represent all of the dates within the monthly interval.

In the following example, the *start-date* (Jan. 14, 2013) is equivalent to the first quarter of 2013.

```
sasdate1=to_double(date'2013-01-14');
sasdate2 = to_double(date'2013-09-02');
qtr=intck('qtr', sasdate1, sasdate2);
```

The *end-date* (September 2, 2013) is equivalent to the third quarter of 2013. The interval count, that is, the number of times the beginning of an interval is reached in moving from the *start-date* to the *end-date* is 2.

The INTCK function using the default discrete method counts the number of times the beginning of an interval is reached in moving from the first date to the second. It does not count the number of complete intervals between two dates:

- The following example returns 0, because the two dates are within the same month.

  ```
  sasdate1=to_double(date'2013-01-01');
  sasdate2 = to_double(date'2013-01-31');
  month=intck(month, sasdate1, sasdate2);
  put month;
  ```

- The following example returns 1, because the two dates lie in different months that are one month apart.

  ```
  sasdate1=to_double(date'2013-01-31');
  sasdate2 = to_double(date'2013-02-01');
  month=intck(month, sasdate1, sasdate2);
  put month;
  ```

- The following example returns –1 because the first date is in a later discrete interval than the second date. (INTCK returns a negative value whenever the

first date is later than the second date and the two dates are not in the same discrete interval.)

```
sasdate1=to_double(date'2013-02-01');
sasdate2 = to_double(date'2013-01-31');
month=intck('month', sasdate1, sasdate2);
put month;
```

Using the discrete method, WEEK intervals are determined by the number of Sundays, the default first day of the week, that occur between the *start-date* and the *end-date*, and not by how many seven-day periods fall between those dates. To count the number of seven-day periods between *start-date* and *end-date*, use the continuous method.

Both the *multiple* and the *shift-index* arguments are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

For more information about working with date and time intervals, see "Date and Time Intervals" in *SAS Functions and CALL Routines: Reference*.

Intervals by Category

Table 7.4 *Intervals Used with Date and Time Functions*

Category	Interval	Definition	Default Starting Point	Shift Period	Example	Description
Date	DAY	Daily intervals	Each day	Days	DAY3	Three-day intervals starting on Sunday
	WEEK	Weekly intervals of seven days	Each Sunday	Days (1=Sunday ... 7=Saturday)	WEEK.7	Weekly with Saturday as the first day of the week
	WEEKDAY <*days*W>	Daily intervals with Friday-Saturday-Sunday	Each day	Days	WEEKDAY1W	Six-day week with Sunday as a weekend day
		counted as the same day (five-day work week with a Saturday-Sunday weekend).			WEEKDAY35W	Five-day week with Tuesday and Thursday as weekend days (W indicates

Category	Interval	Definition	Default Starting Point	Shift Period	Example	Description
		days identifies the weekend days by number (1=Sunday ... 7=Saturday). By default, *days*=17.				that day 3 and day 5 are weekend days)
	TENDAY	Ten-day intervals (a U.S. automobile industry convention)	First, 11th, and 21st of each month	Ten-day periods	TENDAY4.2	Four ten-day periods starting at the second TENDAY period
	SEMIMONTH	Half-month intervals	First and 16th of each month	Semi-monthly periods	SEMIMONTH2.2	Intervals from the 16th of one month through the 15th of the next month
	MONTH	Monthly intervals	First of each month	Months	MONTH2.2	February-March, April-May, June-July, August-September, October-November, and December-January of the following year
	QTR	Quarterly (three-month) intervals	January 1 April 1 July 1 October 1	Months	QTR3.2	Three-month intervals starting on April 1, July 1, October 1, and January 1

Category	Interval	Definition	Default Starting Point	Shift Period	Example	Description
	SEMIYEAR	Semiannual (six-month) intervals	January 1 July 1	Months	SEMIYEAR.3	Six-month intervals, March-August, and September-February
	YEAR	Yearly intervals	January 1	Months		
Datetime	Add DT to any of the date intervals	Interval that corresponds to the associated date interval	Midnight of January 1, 1960		DTMONTH DTWEEKDAY	
Time	SECOND	Second intervals	Start of the day (midnight)	Seconds		
	MINUTE	Minute intervals	Start of the day (midnight)	Minutes		
	HOUR	Hourly intervals	Start of the day (midnight)	Hours		

Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. For more information, see "Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*.

Example

The following programs illustrate the INTCK function:

In the second example, INTCK returns a value of 1 even though only one day has elapsed. This result is returned because the interval from December 31, 2012, to January 1, 2013, contains the starting point for the YEAR interval. However, in the third example, a value of 0 is returned even though 364 days have elapsed. This

result occurs because the period between January 1, 2013, and December 31, 2013, does not contain the starting point for the interval.

In the fourth example, SAS returns a value of 6 because the period of January 1, 2010, through January 1, 2013, contains six semiyearly intervals. (Note that if the ending date were December 31, 2012, SAS would count five intervals.) In the fifth example, SAS returns a value of 6 because there are six two-week intervals beginning on a first Monday during the period of January 7, 2013, through April 1, 2013. In the sixth example, SAS returns the value 27. That indicates that beginning with January 1, 2013, and counting only Saturdays as weekend days through February 1, 2013, the period contains 27 weekdays.

In the seventh example, the use of variables for the arguments is illustrated.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double sasdate1 sasdate2 qtr;
   method run();
      sasdate1 = to_double(date'2013-01-10');
      sasdate2 = to_double(date'2013-07-01');
      qtr=intck('qtr', sasdate1, sasdate2);
      put qtr;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sasdate2 year;
   method run();
      sasdate1 = to_double(date'2012-12-31');
      sasdate2 = to_double(date'2013-01-01');
      year=intck('year', sasdate1, sasdate2);
      put year;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sasdate2 year;
   method run();
      sasdate1 = to_double(date'2013-01-01');
```

```
      sasdate2 = to_double(date'2013-12-31');
      year=intck('year', sasdate1, sasdate2);
      put year;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
0
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sasdate2 semiyear;
   method run();
      sasdate1 = to_double(date'2010-01-01');
      sasdate2 = to_double(date'2013-01-01');
      semiyear=intck('semiyear', sasdate1, sasdate2);
      put semiyear;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
6
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sasdate2 weekvar;
   method run();
      sasdate1 = to_double(date'2013-01-07');
      sasdate2 = to_double(date'2013-04-01');
      weekvar=intck('week2.2', sasdate1, sasdate2);
      put weekvar;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
6
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sasdate2 wdvar;
   method run();
      sasdate1 = to_double(date'2013-01-01');
      sasdate2 = to_double(date'2013-02-01');
      wdvar=intck('weekday7w', sasdate1, sasdate2);
      put wdvar;
   end;
enddata;
```

```
run;
quit;
```

SAS writes the following output to the log.

```
27
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sasdate2 newyears;
   dcl char y;
   method run();
      y='year';
      sasdate1 = to_double(date'2003-09-01');
      sasdate2 = to_double(date'2013-09-01');
      newyears=intck(y, sasdate1, sasdate2);
      put newyears;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
10
```

INTCYCLE Function

Returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified.

Category:	Date and Time
Restriction:	DS2 does not support custom date or time intervals.
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INTCYCLE({*interval*[*multiple*][.*shift-index*]}[, *seasonality*])

Required Argument

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip *Interval* can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

Optional Arguments

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

seasonality

specifies a numeric value. This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

specifies a numeric value.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Default 52

Data type DOUBLE, CHAR, NCHAR, NVARCHAR, VARCHAR

Example The *seasonality* argument in the following example

```
INTCYCLE('MONTH', 3);
```

causes the function call to return the value QTR. The function call

```
INTCYCLE('MONTH');
```

does not have a *seasonality* argument and returns the value YEAR.

Details

The Basics

The INTCYCLE function returns the interval of the seasonal cycle, depending on a date, time, or datetime interval. For example, `INTCYCLE('MONTH');` returns the value YEAR because the months from January through December constitute a yearly cycle. `INTCYCLE('DAY');` returns the value WEEK because the days from Sunday through Saturday constitute a weekly cycle.

For information about multipliers and shift indexes, see "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference*. For information about how intervals are calculated, see "Commonly Used Time Intervals" in *SAS Functions and CALL Routines: Reference*.

For more information about working with date and time intervals, see "Date and Time Intervals" in *SAS Functions and CALL Routines: Reference*..

The INTCYCLE function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Retail

Calendar Intervals: ISO 8601 Compliant" in *SAS Functions and CALL Routines: Reference*.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][*.shift-index*]

For more information, see "Required Argument" on page 741.

Seasonality

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTCYCLE function uses the concept of seasonality and returns the date, time, or datetime interval at the next higher seasonal cycle when a date, time, or datetime interval is specified. For more information about seasonality and using the forecasting methods in PROC FORECAST, see *SAS/ETS User's Guide*.

Example

The following programs illustrate the INTCYCLE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(10) cycle_year;
   method init();
      cycle_year=intcycle('year');
      put cycle_year;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
YEAR
```

```
proc ds2;
data _null_;
```

```
   dcl char(10) cycle_quarter;
   method init();
      cycle_quarter=intcycle('qtr');
      put cycle_quarter;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
YEAR
```

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) cycle_3;
   method init();
      cycle_3=intcycle('month', 3);
      put cycle_3;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
QTR
```

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) cycle_month;
   method init();
      cycle_month=intcycle('month');
      put cycle_month;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
YEAR
```

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) cycle_weekday;
   method init();
      cycle_weekday=intcycle('weekday');
      put cycle_weekday;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
WEEK
```

```
proc ds2;
data  test(overwrite=yes);
   dcl char(10) cycle_weekday2;
   method init();
      cycle_weekday2=intcycle('weekday', 5);
      put cycle_weekday2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
WEEK
```

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) cycle_day;
   method init();
      cycle_day=intcycle('day');
      put cycle_day;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
WEEK
```

```
proc ds2;
data  test(overwrite=yes);
   dcl char(10) cycle_day2;
   method init();
      cycle_day2=intcycle('day', 10);
      put cycle_day2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
TENDAY
```

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) cycle_second;
   dcl char(6) var1;
   method init();
      var1='second';
      cycle_second=intcycle(var1);
      put cycle_second;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
DTMINUTE
```

INTDT Function

Specifies the number of days to add to a DATE value.

Category: Date and Time

Returned data type: DATE

Syntax

INTDT(*expression*, *increment*)

Required Arguments

expression
specifies any valid expression that represents a DATE value.

Data type DATE

See “DS2 Expressions” in *SAS DS2 Programmer's Guide*

increment
specifies a negative, positive, or zero whole number that represents the number of days to add to the date.

Data type DOUBLE

Details

The INTDT function increments a DATE value by the number of days that you specify.

Comparisons

The INTNX function increments a SAS date, time, or datetime value that is encoded as a DOUBLE value.

Example

The following program illustrates the INTDT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl date a b c d;
   method run();
      a= date '2019-05-01';
      b=intdt(a, 25);
      put a;
      put b;
      c= date '2019-05-01';
      d=intdt(c, -25);
      put c;
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2019-05-01
2019-05-26
2019-05-01
2019-04-06
```

INTFIT Function

Returns a time interval that is aligned between two dates.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INTFIT(*expresssion-1*, *expression-2*, '*type*')

Required Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string and that represents a SAS date or datetime value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

'type'
specifies whether the arguments are SAS date values, datetime values, or a row. The following values for *type* are valid: d (date), dt (datetime), and obs (rows).

specifies whether the arguments are SAS date values, datetime values, or a row.

The following values for *type* are valid:

d
specifies that *expression-1* and *expression-2* are date values.

dt
specifies that *expression-1* and *expression-2* are datetime values.

obs
specifies that *expression-1* and *expression-2* are rows.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

The INTFIT function returns the most likely time interval based on two dates, datetime values, or rows that have been aligned within an interval. INTFIT assumes that the alignment value is SAME, which specifies that the date is aligned to the same calendar date with the corresponding interval increment. For more information about the *alignment* argument, see "INTNX Function" in *SAS Functions and CALL Routines: Reference*.

If the arguments that are used with INTFIT are rows, you can determine the cycle of an occurrence by using row numbers. In the following example, the first two arguments of INTFIT are row numbers, and the *type* argument is `obs`. If Jason used the gym the first time and the 25th time that a researcher recorded data, you could determine the interval by using the following statement: `interval=intfit(1, 25, 'obs');`. In this case, the value of interval is OBS24.2.

For information about time series, see *SAS/ETS User's Guide*.

The INTFIT function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*.

Example

The following program illustrates the interval that is aligned between two dates. The *type* argument in this program identifies the input as date values.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2;
   method run();
      sasdate1=to_double(date'2013-08-01');
      sasdate2=to_double(date'2013-09-01');
      c=intfit(sasdate1, sasdate2, 'd');
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
MONTH
```

INTGET Function

Returns a time interval based on three date or datetime values.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INTGET(*date-1*, *date-2*, *date-3*)

Required Argument

date
specifies any valid expression that evaluates to a SAS date or datetime value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Details

INTGET Function Intervals

The INTGET function returns a time interval based on three date or datetime values. The function first determines all possible intervals between the first two dates, and then determines all possible intervals between the second and third dates. If the intervals are the same, INTGET returns that interval. If the intervals for the first and second dates differ, and the intervals for the second and third dates differ, INTGET compares the intervals. If one interval is a multiple of the other, then

INTGET returns the smaller of the two intervals. Otherwise, INTGET returns a missing value. INTGET works best with dates generated by the INTNX function whose alignment value is BEGIN.

In the following example, INTGET returns the interval DAY2:

```
interval=intget('01mar00'd, '03mar00'd, '09mar00'd);
```

The interval between the first and second dates is DAY2, because the number of days between March 1, 2000, and March 3, 2000, is two. The interval between the second and third dates is DAY6, because the number of days between March 3, 2000, and March 9, 2000, is six. DAY6 is a multiple of DAY2. INTGET returns the smaller of the two intervals.

In the following example, INTGET returns the interval MONTH4:

```
interval=intget('01jan00'd, '01may00'd, '01may01'd);
```

The interval between the first two dates is MONTH4, because the number of months between January 1, 2000, and May 1, 2000, is four. The interval between the second and third dates is YEAR. INTGET determines that YEAR is a multiple of MONTH4 (there are three MONTH4 intervals in YEAR), and returns the smaller of the two intervals.

In the following example, INTGET returns a missing value:

```
interval=intget('01Jan2006'd, '01Apr2006'd, '01Dec2006'd);
```

The interval between the first two dates is MONTH3, and the interval between the second and third dates is MONTH8. INTGET determines that MONTH8 is not a multiple of MONTH3, and returns a missing value.

The intervals that are returned are valid SAS intervals, including multiples of the intervals and shift intervals. Valid SAS intervals are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference* .

Note: If INTGET cannot determine a matching interval, then the function returns a missing value. No message is written to the SAS log.

Retail Calendar Intervals

The INTGET function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*.

Example

The following programs illustrate the INTGET function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2 sasdate3;
   method run();
      sasdate1=to_double(date'2013-01-01');
      sasdate2=to_double(date'2014-01-01');
      sasdate3=to_double(date'2014-05-01');
      c=intget(sasdate1, sasdate2, sasdate3);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
MONTH4
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2 sasdate3;
   method run();
      sasdate1=to_double(date'2012-02-29');
      sasdate2=to_double(date'2014-02-28');
      sasdate3=to_double(date'2016-02-29');
      c=intget(sasdate1, sasdate2, sasdate3);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
YEAR2.2
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2 sasdate3;
   method run();
      sasdate1=to_double(date'2013-02-01');
      sasdate2=to_double(date'2013-02-16');
      sasdate3=to_double(date'2013-03-01');
      c=intget(sasdate1, sasdate2, sasdate3);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
SEMIMONTH
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2 sasdate3;
   method run();
      sasdate1=to_double(date'2013-01-02');
      sasdate2=to_double(date'2014-02-02');
      sasdate3=to_double(date'2015-03-02');
      c=intget(sasdate1, sasdate2, sasdate3);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
MONTH13.13
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2 sasdate3;
   method run();
      sasdate1=to_double(date'2013-02-10');
      sasdate2=to_double(date'2013-02-19');
      sasdate3=to_double(date'2013-02-28');
      c=intget(sasdate1, sasdate2, sasdate3);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
DAY9.5
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   dcl double sasdate1 sasdate2 sasdate3;
   method run();
      sasdate1=to_double(timestamp'2014-04-01 01:03:00.0000');
      sasdate2=to_double(timestamp'2014-04-01 01:04:00.0000');
      sasdate3=to_double(timestamp'2014-04-01 01:05:00.0000');
      c=intget(sasdate1, sasdate2, sasdate3);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
MINUTE
```

Functions:

- “INTFIT Function” on page 748
- “INTNX Function” on page 764

INTINDEX Function

Returns the seasonal index when a date, time, or timestamp interval and value are specified.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTINDEX({*interval*[*multiple*][.*shift-index*]}, *date-value*[, *seasonality*])

Required Arguments

interval

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Note: The possible values of *interval* are listed in “About Date and Time Intervals” in *SAS Formats and Informats: Reference*.

Tip: *Interval* can appear in uppercase or lowercase.

Example: YEAR specifies year-based intervals.

date-value

specifies a date, time, or timestamp value that represents a time period of the given interval.

Data type: DOUBLE

Optional Arguments

multiple

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

seasonality

specifies a number or a cycle. This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

specifies a number or a cycle.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Data type DOUBLE, CHAR, NCHAR, NVARCHAR, VARCHAR

Example In this example, the following functions produce the same result.

```
INTINDEX('MONTH', sasdate, 3);
INTINDEX('MONTH', sasdate, 'QTR');
```

Seasonality in the first example is a number (the number of months), and in the second example *seasonality* is a cycle (QTR).

Details

The Basics

The INTINDEX function returns the seasonal index when you supply an interval and an appropriate date, time, or timestamp value. The seasonal index is a number that represents the position of the date, time, or timestamp value in the seasonal cycle of the specified interval. This example returns a value of 12 because there are 12 months in a yearly cycle and December is the 12th month of the year.

```
sasdate=to_double(date'2012-12-01');
x=intindex('month', sasdate);
put x;
```

In the following examples, INTINDEX returns the same value (1) because both statements have dates that occur in the first quarter of the year 2013.

```
sasdate=to_double(date'2013-01-01');
x=intindex('qtr', sasdate);
put x;

sasdate=to_double(date'2013-03-31');
y=intindex('qtr', sasdate);
put y;
```

The following example returns a value of 6 because daily data is weekly periodic and December 7, 2012, is a Friday, the sixth day of the week.

```
sasdate=to_double(date'2012-12-07');
x=intindex('day', sasdate);
put x;
```

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][.*shift-index*]

For more information, see “Required Arguments” on page 754.

How *Interval* and *Date-Time-Value* Are Related

To correctly identify the seasonal index, the interval should agree with the date, time, or timestamp value. For example, `intindex('month', '01DEC2012'd);` returns a value of 12 because there are 12 months in a yearly interval and December is the 12th month of the year. The MONTH interval requires a SAS date value. The following example, returns a value of 6 because there are seven days in a weekly interval and December 7, 2012, is a Friday, the sixth day of the week.

```
sasdate=to_double(date'2012-12-07');
x=intindex('day', sasdate);
put x;
```

The DAY interval requires a SAS date value.

```
select intget('day', date'2012-12-07');
```

This example returns a missing value because the QTR interval expects the date to be a SAS date value rather than a TIMESTAMP value.

```
sasdate=to_double(timestamp'2013-01-01 00:00:00');
x=intindex('qtr', sasdate);
put x;
```

This example returns a value of 12. The DTMONTH interval requires a TIMESTAMP value.

```
sasdate=to_double(timestamp'2013-12-01 00:00:00');
x=intindex('dtmonth', sasdate);
put x;
```

For more information about working with date and time intervals, see "Date and Time Intervals" in *SAS Functions and CALL Routines: Reference*.

Retail Calendar Intervals

The INTINDEX function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Retail Calendar Intervals: ISO 8601 Compliant" in *SAS Functions and CALL Routines: Reference*.

Seasonality

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTINDEX function uses the concept of seasonality and returns the seasonal index when a date, time, or timestamp interval and value are specified. For more information about seasonality and using the forecasting methods in PROC FORECAST, see *SAS/ETS User's Guide*.

Comparisons

The INTINDEX function returns the seasonal index whereas the INTCINDEX function returns the cycle index.

In the following example, the INTINDEX function returns 5 because April 4, 2013 is on a Thursday, the fifth day of the week.

```
sasdate=to_double(date'2013-04-04');
x = intindex('day', sasdate);
put x;
```

Using the same date, the INTCINDEX function returns 14 because April 4, 2013 is the 14th week of the year.

```
sasdate=to_double(date'2013-04-04');
x = intcindex('day', sasdate);
put x;
```

In this example, the INTINDEX function returns the minute of the hour.

```
sasdate=to_double(timestamp'2012-09-01 06:05:04');
x = intindex('minute', sasdate);
put x;
```

Using the same date and time, the INTCINDEX function returns the hour of the day.

```
sasdate=to_double(timestamp'2012-09-01 06:05:04');
y = intcindex('minute', sasdate);
put y;
```

In the example `intseas('interval');`, INTSEAS returns the maximum number that could be returned by `intindex('interval', date);`.

Example

The following programs illustrate the INTINDEX function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 interval1;
   method run();
      sasdate1=to_double(date'2013-08-14');
      interval1 = intindex('qtr', sasdate1);
      put interval1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
3
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasts1 interval2;
   method run();
      sasts1=to_double(timestamp'2013-12-23 15:09:19');
      interval2 = intindex('dtqtr', sasts1);
      put interval2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
4
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sastime1 interval3;
   method run();
      sastime1=to_double(time'09:05:15');
      interval3 = intindex('hour', sastime1);
      put interval3;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
10
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 interval4;
   method run();
      sasdate1=to_double(date '2013-02-26');
      interval4 = intindex('month', sasdate1);
      put interval4;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasts1 interval5;
   method run();
      sasts1=to_double(timestamp'2013-05-28 05:15:00');
      interval5 = intindex('dtmonth', sasts1);
      put interval5;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
5
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 interval6;
   method run();
      sasdate1=to_double(date '2013-09-09');
      interval6 = intindex('week', sasdate1);
      put interval6;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
37
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 interval7;
   method run();
      sasdate1=to_double(date '2013-04-16');
      interval7 = intindex('tenday', sasdate1);
      put interval7;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
11

INTNEST Function

Calculates the number of whole periods of the smaller interval that will fit into the period of the larger interval.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTNEST(*interval1*, *interval2*)

Required Arguments

interval1
specifies the first interval.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

interval2
specifies the second interval.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

An interval nests within another interval when a whole number of the first interval spans the same time period as the second interval for all time periods. In order to nest, the two intervals must generate beginning and ending dates that align.

If the first interval, *interval1*, spans a larger time period than the second interval, *interval2*, then the returned number is positive. If the second interval spans a larger period than the first interval, then the returned number is negative.

The following time series tasks are related to the INTNEST function:

accumulation
if one interval nests into another interval, even with a variable number, accumulation from the smaller time periods into the larger time periods is accomplished with a simple rule. If the intervals do not nest, consider transforming a time series from one frequency to another with a more complex rule (for example, an interpolation).

seasonality
: many seasonal models require that the higher frequency interval nest into the lower frequency seasonal interval with a fixed number of periods.

time reconciliation
: time reconciliation requires that the higher frequency interval nest into the lower frequency interval.

The following table contains the types and descriptions of results that are returned by the INTNEST function:

Table 7.5 *INTNEST Function Results and Descriptions*

Result	Description	Explanation or Example
0	Same	The two input intervals define the same time periods for all time periods. `intnest('month12','year')`
1	Variable Number	The first interval contains a whole number of periods of the second interval, but the number varies over time. `intnest('month','day')`
-1	Variable Number	The second interval contains a whole number of periods of the first interval, but the number varies over time. `intnest('day',''year')`
n > 1	Fixed Number	The first interval contains a whole number *n* periods of the second interval, and that is fixed for all time. `intnest('week', 'day')`
n < -1	Fixed Number	The second interval contains a whole number *n* periods of the first interval, and that is fixed for all time. `intnest('dthour', 'day')`
Missing value of M	Multiple Mismatch	Both intervals cannot nest into the other interval. However, intervals of these types can nest for some multiple values. `intnest('semimonth3', 'month')`
Missing value of S	Shift Mismatch	Both intervals cannot nest into the other interval. However, if a shift value is changed, then either the intervals would be the same or one interval would nest into the other. `intnest('semimonth2.2', 'month')`

Result	Description	Explanation or Example
Missing value of B	Base Mismatch	The interval bases define time periods that are so different that nesting is not possible for any multiple or shift. For example, YEAR always begins on January 1 of each year and is shifted by months. However, YEARV always begins on the Monday on or immediately preceding January 4, and YEARV is shifted by ISO 8601 weeks that begin on Monday. Since January 1 is only a Monday for some years, the intervals will not consistently start on the same day. The same problem exists if the YEAR interval is shifted by months, since the first of a month would not be a Monday for all years. `intnest('year', 'yearv')`

Example

The following program illustrates the INTNEST function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a;
   dcl char(10) x y;
   method run();
      x='SEMIMONTH3';
      y='MONTH';
      a=intnest(x, y);
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
M
```

INTNX Function

Increments a SAS date, time, or datetime value encoded as a DOUBLE, and returns a SAS date, time, or datetime value encoded as a DOUBLE.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTNX({*interval*[*multiple*][*.shift-index*]}, *start-from*, *increment*[, '*alignment*'])

INTNX(*start-from*, *increment*[, '*alignment*'])

Required Arguments

interval

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Note: The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip: *Interval* can appear in uppercase or lowercase.

Example: YEAR specifies year-based intervals.

start-from

specifies an expression that represents a SAS date, time, or datetime value encoded as a DOUBLE and that identifies a starting point.

Data type: DOUBLE

increment

specifies a negative, positive, or zero whole number that represents the number of date, time, or datetime intervals. *Increment* is the number of intervals to shift the value of *start-from*.

Data type: DOUBLE

Optional Arguments

multiple

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

'alignment'

controls the position of SAS dates within the interval. You must enclose *alignment* in quotation marks. *Alignment* can be one of these values: BEGINNING, MIDDLE, END, and SAME. SAME specifies that the date that is returned has the same alignment as the input date. For more information, see SAS DS2 Language Reference.

controls the position of SAS dates within the interval. You must enclose *alignment* in quotation marks. *Alignment* can be one of these values:

BEGINNING
specifies that the returned date or datetime value is aligned to the beginning of the interval.

Alias B

MIDDLE
specifies that the returned date or datetime value is aligned to the midpoint of the interval, which is the average of the beginning and ending alignment values.

Alias M

END
specifies that the returned date or datetime value is aligned to the end of the interval.

Alias E

SAME
specifies that the date that is returned has the same alignment as the input date.

Aliases S

SAMEDAY

See "SAME Alignment" on page 767

Default BEGINNING

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "Aligning SAS Date Output within Its Intervals" on page 767

Details

The Basics

The INTNX function increments a date, time, or datetime value by intervals such as DAY, WEEK, QTR, and MINUTE, or a custom interval that you define. The increment is based on a starting date, time, or datetime value, and on the number of time intervals that you specify.

The INTNX function returns the SAS date value for the beginning date, time, or datetime value of the interval that you specify in the *start-from* argument. (To convert the date value to a calendar date, use any valid DS2 date format, such as the DATE9. format.) The following example shows how to determine the date of the start of the week that is six weeks from the week of October 17, 2011.

```
sasdate=to_double(date'2011-10-17');
x=intnx('week', sasdate, 6);
put x date9.;
```

INTNX returns the value 27NOV2011.

For more information about working with date and time intervals, see "Date and Time Intervals" in *SAS Functions and CALL Routines: Reference*.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][.*shift-index*]

For more information, see "Required Arguments" on page 764.

Aligning SAS Date Output within Its Intervals

SAS date values are typically aligned with the beginning of the time interval that is specified with the *interval* argument.

You can use the optional *alignment* argument to specify the alignment of the date that is returned. The values BEGINNING, MIDDLE, or END align the date to the beginning, middle, or end of the interval, respectively.

SAME Alignment

If you use the SAME value of the *alignment* argument, then INTNX returns the same calendar date after computing the interval increment that you specified. The same calendar date is aligned based on the interval's shift period, not the interval. To view the valid shift periods, see "Intervals by Category" on page 735.

Most of the values of the shift period are equal to their corresponding intervals. The exceptions are the intervals WEEK, WEEKDAY, QTR, SEMIYEAR, YEAR, and their DT counterparts. WEEK and WEEKDAY intervals have a shift period of DAYS; and QTR, SEMIYEAR, and YEAR intervals have a shift period of MONTH. For example, when you use SAME alignment with YEAR, the result is same-day alignment based on MONTH, the interval's shift period. The result is not aligned to the same day of the YEAR interval. If you specify a multiple interval, then the default shift interval is based on the interval, and not on the multiple interval.

When you use SAME alignment for QTR, SEMIYEAR, and YEAR intervals, the computed date is the same number of months from the beginning of the interval as the input date. The day of the month matches as closely as possible. Because not all months have the same number of days, it is not always possible to match the day of the month.

For more information about shift periods, see "Intervals by Category" on page 735.

Alignment Intervals

Use the SAME value of the *alignment* argument if you want to base the alignment of the computed date on the alignment of the input date.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x having format date9.;
   dcl double y having format datetime.;
   dcl double z having format date9.;
   dcl double sasdatex sasdatey sasdatez;
   method init();
      sasdatex=to_double(date'2011-03-15');
      x=intnx('week', sasdatex, 1, 'same');
      sasdatey=to_double(timestamp'2011-03-15 08:45:00');
      y=intnx('dtweek', sasdatey, 1, 'same');
      sasdatez=to_double(date'2011-03-15');
      z=intnx('year', sasdatez, 5, 'same');
      put x;
      put y;
      put z;
   end;
enddata;
run;
quit;
```

Adjusting Dates

The INTNX function automatically adjusts for the date if the date in the interval that is incremented does not exist. Here is an example:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b c  d e having format date9.;
   dcl double sasdate;
   method init();
      sasdate=to_double(date'2011-03-15');
      a=intnx('month', sasdate, 5, 'same');
      put a;
      sasdate=to_double(date'2012-02-29');
      b=intnx('year', sasdate, 2, 'same');
      put b;
      sasdate=to_double(date'2011-08-31');
      c=intnx('month', sasdate, 1, 'same');
      put c;
      sasdate=to_double(date'2011-03-01');
      d=intnx('year', sasdate, 1, 'same');
      put d;
      sasdate=to_double(date'2011-03-01');
      e=intnx('year', sasdate, 1, 'same', 'day');
      put e;
   end;
enddata;
run;
quit;
```

In the following example, the INTNX function returns the value 01JAN2014, which is the beginning of the year two years from the starting date (29FEB2012).

```
dcl double a having format date9.;
sasdate=to_double(date'2012-02-29');
a=intnx('year', sasdate, 2);
put a;
```

In this example , the INTNX function returns the value 28FEB2014. In this case, the starting date begins in the year 2012, the year is two years later (2014), the month is the same (February), and the date is the 28th, because that is the closest date to the 29th in February 2014.

```
dcl double b having format date9.;
sasdate=to_double(date'2012-02-29');
b=intnx('year', sasdate, 2, 'same');
put b;
```

Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. For more information, see "Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*.

Examples

Example 1: Using the INTNX Function

The following programs illustrate the INTNX function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 yr;
   method run();
      sasdate1 = to_double(date'2019-02-05');
      yr=intnx('year', sasdate1, 3);
      put yr;
      put yr date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
22646
01JAN22
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   method run();
      sasdate1 = to_double(date'2019-01-05');
      x=intnx('month', sasdate1, 0);
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21550
01JAN19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 next;
   method run();
      sasdate1 = to_double(date'2019-01-01');
      next=intnx('semiyear', sasdate1, 1);
      put next;
      put next date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21731
01JUL19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 past;
   method run();
      sasdate1 = to_double(date'2019-08-01');
      past=intnx('month2', sasdate1, -1);
      put past;
      put past date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21670
01MAY19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 sm;
```

```
   method run();
      sasdate1 = to_double(date'2019-04-01');
      sm=intnx('semimonth2.2', sasdate1, 4);
      put sm;
      put sm date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21746
16JUL19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 nextmon;
   dcl char x;
   method run();
      x='month';
      sasdate1 = to_double(date'2019-06-01');
      nextmon=intnx(x, sasdate1, 1);
      put nextmon;
      put nextmon date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21731
01JUL19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   dcl char m1 m2;
   method run();
      m1='month     ';
      m2=trim(m1);
      sasdate1 = to_double(date'2019-06-15') - 100;
      x=intnx(m2, sasdate1, 1);
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21640
01APR19
```

Example 2: Using the ALIGNMENT Argument

The following programs show the results of advancing a date by using the optional *alignment* argument.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   method run();
      sasdate1 = to_double(date'2019-01-01');
      x=intnx('month', sasdate1, 5, 'beginning');
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21701
01JUN19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   method run();
      sasdate1 = to_double(date'2019-01-01');
      x=intnx('month', sasdate1, 5, 'middle');
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21715
15JUN19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   method run();
      sasdate1 = to_double(date'2019-01-01');
      x=intnx('month', sasdate1, 5, 'end');
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21730
30JUN19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   method run();
      sasdate1 = to_double(date'2019-01-01');
      x=intnx('month', sasdate1, 5, 'sameday');
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21701
01JUN19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   method run();
      sasdate1 = to_double(date'2019-03-15');
      x=intnx('month', sasdate1, 5, 'same');
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21776
15AUG19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   dcl char interval align;
   method run();
      interval='month';
      align='m';
      sasdate1 = to_double(date'2019-09-01');
      x=intnx(interval, sasdate1,2, align);
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21868
15NOV19
```

```
proc ds2;
data test (overwrite=yes);
   dcl double sasdate1 x;
   dcl char m1 m2;
   method run();
      m1='month     ';
      m2=trim(m1);
      sasdate1 = to_double(date'2019-09-01');
      x=intnx(m2, sasdate1, 2, 'm');
      put x;
      put x date7.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
21868
15NOV19
```

INTRR Function

Returns the internal rate of return as a decimal value.

Category:	Financial
Returned data type:	DOUBLE

Syntax

INTRR(*freq*, *c0, c1*[*..., cn*])

Required Arguments

freq
is numeric, the number of payments over a specified base period of time that is associated with the desired internal rate of return.

Range *freq* > 0

Data type DOUBLE

Tip The case *freq* = 0 is a flag to allow continuous compounding.

***c0, c1*[*..., cn*]**
are numeric, the optional cash payments.

Data type DOUBLE

Details

The INTRR function returns the internal rate of return over a specified base period of time for the set of cash payments *c0*, *c1*, ..., *cn*. The time intervals between any two consecutive payments are assumed to be equal. The argument *freq* > 0 describes the number of payments that occur over the specified base period of time. The number of notes issued from each instance is limited.

The internal rate of return is the interest rate such that the sequence of payments has a 0 net present value. (See the "NPV Function" on page 920.) It is given by the following equation.

$$r = \begin{cases} \frac{1}{x^{freq}} - 1 & freq > 0 \\ -log_{\varepsilon}(x) & freq = 0 \end{cases}$$

In this equation, *x* is the real root of the polynomial.

$$\sum_{i=0}^{n} c_i x^i = 0$$

In the case of multiple roots, one real root is returned and a warning is issued concerning the non-uniqueness of the returned internal rate of return. Depending on the value of payments, a root for the equation does not always exist. In that case, a missing value is returned.

Missing values in the payments are treated as 0 values. When *freq* > 0, the computed rate of return is the effective rate over the specified base period. To compute a quarterly internal rate of return (the base period is three months) with monthly payments, set *freq* to 3.

If *freq* is 0, continuous compounding is assumed and the base period is the time interval between two consecutive payments. The computed internal rate of return is the nominal rate of return over the base period. To compute with continuous compounding and monthly payments, set *freq* to 0. The computed internal rate of return is a monthly rate.

Comparisons

The IRR function is identical to INTRR, except for in the IRR function, the internal rate of return is a percentage.

Example

For an initial outlay of $400 and expected payments of $100, $200, and $300 over the following three years, the annual internal rate of return can be calculated as follows:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double rate;
   method init();
      rate=intrr(1,-400,100,200,300);
      put rate;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
0.19437709962747
```

```
0.1943770996
```

INTSEAS Function

Returns the length of the seasonal cycle when a date, time, or datetime interval is specified.

Category: Date and Time

Restriction: DS2 does not support custom date or time intervals.

Returned data type: DOUBLE

Syntax

INTSEAS({*interval*[*multiple*][.*shift-index*]}[, *seasonality*])

Required Argument

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip *Interval* can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

Optional Arguments

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

seasonality

specifies a numeric value. This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

specifies a numeric value.

This argument enables you to have more flexibility in working with dates and time cycles. You can specify whether you want a 52-week or a 53-week seasonality in a year.

Default 52

Data type DOUBLE, CHAR, NCHAR, NVARCHAR, VARCHAR

Example The *seasonality* argument in the following example

```
INTSEAS('MONTH', 'qtr');
```

causes the function call to return the value 3. The function call

```
INTSEAS('MONTH');
```

does not have a *seasonality* argument and returns the value 12.

Details

The Basics

The INTSEAS function returns the number of intervals in a seasonal cycle. For example, when the interval for a time series is described as monthly, then many procedures use the option INTERVAL=MONTH. Each observation in the data then corresponds to a particular month. Monthly data is considered to be periodic for a one-year period. A year contains 12 months, so the number of intervals (months) in a seasonal cycle (year) is 12.

Quarterly data is also considered to be periodic for a one-year period. A year contains four quarters, so the number of intervals in a seasonal cycle is four.

The periodicity is not always one year. For example, INTERVAL=DAY is considered to have a period of one week. Because there are seven days in a week, the number of intervals in the seasonal cycle is seven.

For more information about working with date and time intervals, see "Date and Time Intervals" in *SAS Functions and CALL Routines: Reference*.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][*.shift-index*]

For more information, see "Required Argument" on page 777.

Retail Calendar Intervals

The retail industry often accounts for its data by dividing the yearly calendar into four 13-week periods, based on one of the following formats: 4-4-5, 4-5-4, or 5-4-4. The first, second, and third numbers specify the number of weeks in the first, second, and third month of each period, respectively. For more information, see "Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*.

Seasonality

Seasonality is a time series concept that measures cyclical variations at different intervals during the year. In specifying seasonality, the time of year is the most common source of the variations. For example, sales of home heating oil are regularly greater in winter than during other times of the year. Often, certain days of the week cause regular fluctuations in daily time series, such as increased spending on leisure activities during weekends. The INTSEAS function uses the concept of seasonality and returns the length of the seasonal cycle when a date, time, or datetime interval is specified. For more information about seasonality and forecasting, see *SAS/ETS User's Guide*.

Example

The following program illustrates the INTSEAS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double cycle_years cycle_smiyears cycle_quarters cycle_number;
   dcl double cycle_months cycle_smimonths cycle_tendays;
   dcl double cycle_weeks cycle_wkdays cycle_hours  cycle_minutes;
   dcl double cycle_minutes cycle_month2 cycle_week2 cycle_var1;
   dcl double cycle_day1;
   dcl char var1;
   method run();
      cycle_years = intseas('year');
      put cycle_years;

      cycle_smiyears = intseas('semiyear');
      put cycle_smiyears;

      cycle_quarters = intseas('quarter');
      put cycle_quarters;

      cycle_number = intseas('month', 'qtr');
      put cycle_number;

      cycle_months = intseas('month');
      put cycle_months;

      cycle_smimonths = intseas('semimonth');
      put cycle_smimonths;

      cycle_tendays = intseas('tenday');
      put cycle_tendays;

      cycle_weeks = intseas('week');
      put cycle_weeks;

      cycle_wkdays = intseas('weekday');
      put cycle_wkdays;

      cycle_hours = intseas('hour');
      put cycle_hours;

      cycle_minutes = intseas('minute');
      put cycle_minutes;

      cycle_month2 = intseas('month2.2');
      put cycle_month2;

      cycle_week2 = intseas('week2');
      put cycle_week2;
```

```
        var1 = 'month4.3';
        cycle_var1 = intseas(var1);
        put cycle_var1;

        cycle_day1 = intseas('day1');
        put cycle_day1;

    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
2
4
3
12
24
36
52
5
24
60
6
26
3
7
```

- *SAS/ETS User's Guide*

INTSHIFT Function

Returns the shift interval that corresponds to the base interval.

Category:	Date and Time
Restriction:	DS2 does not support custom date or time intervals.
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

INTSHIFT(*interval*[*multiple*][.*shift-index*])

Required Argument

interval

specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip *Interval* can appear in uppercase or lowercase.

Example YEAR specifies yearly intervals.

Optional Arguments

multiple

specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 consists of two-year, or biennial, periods.

shift-index

specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type	DOUBLE
See	"Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.
Example	YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Details

The Basics

The INTSHIFT function returns the shift interval that corresponds to the base interval. For custom intervals, the value that is returned is the base custom interval name. INTSHIFT ignores multiples of the interval and interval shifts.

The INTSHIFT function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Working with Dates and Times by Using the ISO 8601 Basic and Extended Notations" in *SAS Formats and Informats: Reference*.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][*.shift-index*]

For more information, see "Required Argument" on page 782.

Example

The following programs illustrate the INTSHIFT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   method run();
      c=intshift('year');
      put c;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
MONTH
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   method run();
      c=intshift('dtyear');
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
DTMONTH
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   method run();
      c=intshift('minute');
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
DTMINUTE
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c x;
   method run();
      x='weekdays';
      c=intshift(x);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
WEEKDAY
```

```
proc ds2;
data test (overwrite=yes);
```

```
   dcl char(10) c;
   method run();
      c=intshift('weekdays5.4');
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
WEEKDAY
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   method run();
      c=intshift('qtr');
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
MONTH
```

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) c;
   method run();
      c=intshift('dttenday');
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
DTTENDAY
```

INTTEST Function

Returns 1 if a time interval is valid, and returns 0 if a time interval is invalid.

Category:	Date and Time
Restriction:	DS2 does not support custom date or time intervals.
Returned data type:	DOUBLE

Syntax

INTTEST(*interval*[*multiple*][.*shift-index*])

Required Argument

interval
specifies a character constant, a variable, or an expression that evaluates or can be coerced to a character string and that contains an interval name such as WEEK, MONTH, or QTR.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note The possible values of *interval* are listed in "About Date and Time Intervals" in *SAS Formats and Informats: Reference*.

Tip *Interval* can appear in uppercase or lowercase.

Example YEAR specifies year-based intervals.

Optional Arguments

multiple
specifies an optional multiplier that sets the interval equal to a multiple of the period of the basic interval type.

Data type DOUBLE

See "Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.

Example YEAR2 specifies a two-year, or biennial, interval type.

shift-index
specifies an optional shift index that shifts the interval to start at a specified subperiod starting point.

Restrictions The shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no 25th month in a two-year interval.

If the default shift period is the same as the interval type, then only multiperiod intervals can be shifted with the optional shift index. For example, because MONTH type intervals shift by MONTH subperiods by default, monthly intervals cannot be shifted with the shift index. However, bimonthly intervals can be shifted with the shift index, because there are two MONTH intervals in each MONTH2 interval. For example, the interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Data type	DOUBLE
See	"Incrementing Dates and Times By Using Multipliers and By Shifting Intervals" in *SAS Functions and CALL Routines: Reference* for more information.
Example	YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Details

The Basics

The INTTEST function checks for a valid interval name. This function is useful when checking for valid values of *multiple* and *shift-index*. For more information about multipliers and shift indexes, see "Multiunit Intervals" in *SAS Programmer's Guide: Essentials*.

The INTTEST function can also be used with calendar intervals from the retail industry. These intervals are ISO 8601 compliant. For more information, see "Dates, Times, and Intervals" in *SAS Programmer's Guide: Essentials*.

Intervals

Intervals can be basic or complex. The basic interval is a unit of measurement that SAS can count within an elapsed period of time, such as a DAY, MONTH, or HOUR. Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications.

The interval syntax is as follows:

interval[*multiple*][.*shift-index*]

For more information, see "Required Argument" on page 786.

Example

In the following program, SAS returns a value of 1 if the *interval* argument is valid, and 0 if the interval argument is invalid.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double test1 test2 test3 test4 test5;
   dcl char var1;
   method run();
      test1 = inttest('month');
```

```
        put test1;

        test2 = inttest('week6.13');
        put test2;

        test3 = inttest('tenday');
        put test3;

        test4 = inttest('twoweeks');
        put test4;

        var1 = 'hour2.2';
        test5 = inttest(var1);
        put test5;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
1
1
1
0
1
```

INTTS Function

Specifies the number of seconds to add to a TIMESTAMP value.

Category: Date and Time

Returned data type: TIMESTAMP

Syntax

INTTS(*expression*, *increment*)

Required Arguments

expression
specifies any valid expression that represents a TIMESTAMP value.

Data type TIMESTAMP

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

increment
specifies a negative, positive, or zero whole number that represents the number of seconds to add to the time.

Data type DOUBLE

Details

The INTTS function increments a TIMESTAMP value by the number of seconds that you specify.

Comparisons

The INTNX function increments a SAS date, time, or datetime value encoded as a DOUBLE value.

Example

The following programs illustrate the INTTS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl timestamp y z;
   method init();
      y= timestamp '2019-03-01 16:51:36.00';
      z=intts(y, 43);
      put y;
      put z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2019-03-01 16:51:36
2019-03-01 16:52:19
```

```
proc ds2;
data _null_;
   dcl timestamp y z;
   dcl date a;
   method init();
      a= date '2019-01-01';
      y= timestamp '2019-05-01 02:58:17.00';
```

```
        z=intts(y, -2500);
        put a;
        put y;
        put z;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2019-01-01
2019-05-01 02:58:17
2019-05-01 02:16:37
```

See Also

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Functions:

- "INTCK Function" on page 731

- "INTNX Function" on page 764

INTZ Function

Returns the whole number portion of the argument, using zero fuzzing.

Category: Truncation

Returned data type: DOUBLE

Syntax

INTZ(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The following rules apply:

- If the value of the argument is an exact whole number, INTZ returns that whole number.
- If the argument is positive and not a whole number, INTZ returns the largest whole number that is less than the argument.
- If the argument is negative and not a whole number, INTZ returns the smallest whole number that is greater than the argument.

Comparisons

Unlike the INT function, the INTZ function uses zero fuzzing. If the argument is within 1E-12 of a whole number, the INT function fuzzes the result to be equal to that whole number. The INTZ function does not fuzz the result. Therefore, with the INTZ function, you might get unexpected results.

Example

The following program illustrates the INTZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double var1 var2 var3 var4 a b c d ;
   method run();
      var1=2.1;
      a=intz(var1);
      put a;
      var2=-2.4;
      b=intz(var2);
      put b;
      var3=1+1.e-11;
      c=intz(var3);
      put c;
      var4=-1.6;
      d=intz(var4);
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
2
-2
1
-1
```

IPMT Function

Returns the interest payment for a given period for a constant payment loan or the periodic savings for a future balance.

Category: Financial

Returned data type: DOUBLE

Syntax

IPMT(*rate*, *period*, *number-of-periods*, *principal-amount*[, *future-amount*][, *type*])

Required Arguments

rate
specifies the interest rate per payment period.

Data type DOUBLE

period
specifies the payment period for which the interest payment is computed.

Requirement *Period* must be a positive whole number that is less than or equal to the value of *number-of-periods*.

Data type INTEGER

number-of-periods
specifies the number of payment periods.

Requirement *Number-of-periods* must be a positive whole number.

Data type INTEGER

principal-amount
specifies the principal amount of the loan.

Data type DOUBLE

Note Zero is assumed if a missing value is specified.

Optional Arguments

future-amount
specifies the future amount.

Data type DOUBLE

Notes *Future-amount* can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic savings.

Zero is assumed if *future-amount* is omitted or if a missing value is specified.

type
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments.

Data type INTEGER

Note 0 is assumed if *type* is omitted or if a missing value is specified.

Example

The interest payment on the first periodic payment of an $8,000 loan, where the nominal annual interest rate is 10% and the end-of-period monthly payments are 36, is computed as follows:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data test (overwrite=yes);
   dcl double interestpaid1;
   method run();
      InterestPaid1 = ipmt(0.1/12, 1, 36, 8000);
      put interestpaid1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
66.6666666666666

66.66667
```

If the same loan has beginning-of-period payments, then the interest payment can be computed as follows:

- ```
  proc ds2;
  data test (overwrite=yes);
     dcl double interestpaid2;
     method run();
        InterestPaid2 = ipmt(0.1/12, 1, 36, 8000, 0, 1);
        put interestpaid2;
     end;
  enddata;
  run;
  quit;
  ```
  This computation returns a value of 0.

- ```
  proc ds2;
  data test (overwrite=yes);
     dcl double interestpaid3;
     method run();
        InterestPaid3 = ipmt(0.1, 3, 3, 8000);
        put interestpaid3;
     end;
  enddata;
  run;
  quit;
  ```
  This computation returns a value of 292.447129909366.

- ```
  proc ds2;
  data test (overwrite=yes);
     dcl double interestpaid4;
     method run();
        InterestPaid4 = ipmt(0.09/12, 359, 360, 125000, 0, 1);
        put interestpaid4;
     end;
  enddata;
  run;
  quit;
  ```
  This computation returns a value of 14.8075736630449.
  ```

IQR Function

Returns the interquartile range.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

IQR(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If all arguments have null or missing values, the result is a null or missing value depending on whether you are in ANSI mode or SAS mode. For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

Otherwise, the result is the interquartile range of the non-null or nonmissing values. The formula for the interquartile range is the same as the one that is used in the UNIVARIATE procedure. For more information, see *Base SAS Procedures Guide: Statistical Procedures*.

Example

The following program illustrates the IQR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a;
```

```
      method run();
         a=iqr(2,4,1,3,999999);
         put  'a= ' a;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log.

```
2
```

See Also

Functions:

- "MAD Function" on page 846
- "PCTL Function" on page 927

IRR Function

Returns the internal rate of return as a percentage.

Category:	Financial
Returned data type:	DOUBLE

Syntax

IRR(*freq*, *c1, c2* [*..., cn*])

Required Arguments

freq
is numeric, the number of payments over a specified base period of time that is associated with the desired internal rate of return.

Range	*freq* > 0.
Data type	DOUBLE
Tip	The case *freq* = 0 is a flag to allow continuous compounding.

***c1, c2*[*..., cn*]**
are numeric, the optional cash payments.

Requirement	At minimum, two cash payment values are required.
Data type	DOUBLE

Details

The IRR function returns the internal rate of return over a specified base period of time for the set of cash payments *c1*, *c2*, ..., *cn*. The time intervals between any two consecutive payments are assumed to be equal. The argument *freq* > 0 describes the number of payments that occur over the specified base period of time. The number of notes issued from each instance is limited.

Comparisons

The IRR function is identical to INTRR, except that in the IRR function, the internal rate of return is a percentage.

Example

For an initial outlay of $400 and expected payments of $100, $200, and $300 over the following three years, the annual internal rate of return as a percentage can be expressed by the following program:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double rate2;
   method run();
      rate2=irr(1,-400,100,200,300);
      put rate2;
   end;
enddata;
run;
quit;
```

The value that is returned is 19.437709962747.

Functions:

- “INTRR Function” on page 774

JBESSEL Function

Returns the value of the Bessel function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

JBESSEL(*nu*, *x*)

Required Arguments

nu

specifies a numeric constant, variable, or expression.

Range *nu* ≥ 0

x

specifies a numeric constant, variable, or expression.

Range *x* ≥ 0

Details

The JBESSEL function returns the value of the Bessel function of order *nu* evaluated at *x* (For more information, see Abramowitz and Stegun 1964; Amos, Daniel, and Weston 1977).

Example

The following program illustrates the JBESSEL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=jbessel(2,2);
      put x;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.35283402861563
```

Functions:

- "IBESSEL Function" on page 708

JULDATE Function

Returns the Julian date from a SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

JULDATE(*date*)

Required Argument

date
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

A SAS date value is a number that represents the number of days from January 1, 1960 to a specific date. The JULDATE function converts a SAS date value to a Julian date. If *date* falls within the 100-year span defined by the system option YEARCUTOFF=, the result has three, four or five digits: In a five-digit result, the first two digits represent the year, and the next three digits represent the day of the

year (1 to 365, or 1 to 366 for leap years). As leading zeros are dropped from the result, the year portion of a Julian date can be omitted (for years ending in 00) or it can have only one digit (for years ending 01–09). Otherwise, the result has seven digits: the first four digits represent the year, and the next three digits represent the day of the year.

For years that end between 00–09, you can format the five-digit Julian date by using the Z5. format.

For more information about how DS2 handles dates, see "DS2 Expressions" in *SAS DS2 Programmer's Guide*.

Comparisons

The function JULDATE7 is similar to JULDATE except that JULDATE7 always returns a four-digit year. Thus, JULDATE7 is year 2000 compliant because it eliminates the need to consider the implications of a two-digit year.

Example

The following program illustrates the JULDATE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double julian1 julian3 julian4;
   dcl double julian2 having format z5.;
   method run();
      julian1=juldate(mdy(12,31,2007));
      put julian1;
      julian2=juldate(mdy(12,31,2007));
      put julian2;
      julian3=juldate(mdy(9,1,1999));
      put julian3;
      julian4=juldate(mdy(7,1,1886));
      put julian4;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
7365
07365
99244
1886182
```

Functions:

- “DATEJUL Function” on page 501
- “JULDATE7 Function” on page 801

JULDATE7 Function

Returns a seven-digit Julian date from a SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

JULDATE7(*date*)

Required Argument

date
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

A SAS date value is a number that represents the number of days from January 1, 1960 to a specific date. The JULDATE7 function returns a seven-digit Julian date from a SAS date value. The first four digits represent the year, and the next three digits represent the day of the year.

For more information about how DS2 handles dates, see “DS2 Expressions” in *SAS DS2 Programmer’s Guide*.

Comparisons

The function JULDATE7 is similar to JULDATE except that JULDATE7 always returns a four-digit year. Thus, JULDATE7 is year 2000 compliant because it eliminates the need to consider the implications of a two-digit year.

Example

The following program illustrates the JULDATE7 function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double julian7;
   method run();
      julian7=juldate7(mdy(12,31,1996));
      put julian7=;
      julian7=juldate7(mdy(1,1,2099));
      put julian7=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
julian7=1996366
julian7=2099001
```

Functions:

- “JULDATE Function” on page 799

KURTOSIS Function

Returns the kurtosis.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

KURTOSIS(*expression-1, expression-2, expression-3, expression-4* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement	At least four non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.
Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

Kurtosis is primarily a measure of the heaviness of the tails of a distribution. Large kurtosis values indicate that the distribution has heavy tails.

Null values and missing values are ignored and are not included in the computation.

If all non-null or nonmissing arguments have equal values, the kurtosis is mathematically undefined and the KURTOSIS function returns a null or missing value.

Example

The following program illustrates the KURTOSIS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3 x4 x5;
   method run();
      x1=kurtosis(5, 9, 3, 6);
      x2=kurtosis(5, 8, 9, 6, .);
      x3=kurtosis(8, 9, 6, 1);
      x4=kurtosis(8, 1, 6, 1);
      x5=kurtosis(of x1-x4);
      put _all_;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=0.92799999999999 x2=-3.3 x3=1.5 x4=-4.48337950138504 x5=-5.06569275379433 _N_=1
```

LAG Function

Returns values from a queue.

Category: Special

Returned data type: Same as the expression's data type

Syntax

LAG [*n*] (*expression*)

Required Argument

expression
specifies any valid expression.

Data type ANY

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

n
specifies the number of lagged values.

Range 1 to 100

Data type Integer

Details

The Basics

If the LAG function returns a value to a character variable that has not yet been assigned a length, by default the variable is assigned the same length as the variable used in the argument.

The LAG functions, LAG1, LAG2, ..., LAG*n* return values from a queue. LAG1 can also be written as LAG. A LAG*n* function stores a value in a queue and returns the value supplied by the *n*th previous call. Each occurrence of a LAG*n* function in a program generates its own queue of values.

The queue for each occurrence of LAG*n* is initialized with *n* missing values, where *n* is the length of the queue (for example, a LAG2 queue is initialized with two missing values). When an occurrence of LAG*n* is executed, the value at the top of its queue is removed and returned, the remaining values are shifted upward, and the new value of the argument is placed at the bottom of the queue. Hence, missing values are returned for the first *n* executions of each occurrence of LAG*n*, after which the lagged values of the argument begin to appear.

Note: Storing values at the bottom of the queue and returning values from the top of the queue occurs only when the function is executed. An occurrence of the LAG*n* function that is executed conditionally stores and return values only from the observations for which the condition is satisfied.

TIP If the argument of LAG*n* is an array element, such as X[i], a separate queue is maintained for each index into the array.

Memory Limit for the LAG Function

When the LAG function is compiled, SAS allocates memory in a queue to hold the values of the variable that is listed in the LAG function. For example, if the variable in function LAG100(x) is numeric with a length of 8 bytes, then the memory that is needed is 8 times 100, or 800 bytes. Therefore, the memory limit for the LAG function is based on the memory that SAS allocates, which varies with different operating environments.

Examples

Example 1: Generating Two Lagged Values

The following program generates two lagged values for each observation.

LAG1 returns one missing value and the values of X (lagged once). LAG2 returns two missing values and the values of X (lagged twice).

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data two (overwrite=yes);
   dcl char(8) x y z;
   method run();
      do x='abc', 'def','ghi','jkl','mno','pqr';
         y=lag1(x);
         z=lag2(x);
         output;
      end;
   end;
enddata;
run;
```

```
quit;

proc print data=two;
   title LAG Output;
run;
```

Output 7.11 *Output from Generating Two Lagged Values*

LAG Output

Obs	x	y	z
1	abc		
2	def	abc	
3	ghi	def	abc
4	jkl	ghi	def
5	mno	jkl	ghi
6	pqr	mno	jkl

Example 2: Generating a Fibonacci Sequence of Numbers

The following program generates a Fibonacci sequence of numbers. You start with 0 and 1, and then add the two previous Fibonacci numbers to generate the next Fibonacci number.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl int n f;
   method run();
      put 'Fibonacci Sequence';
      n=1;
      f=1;
      put n= f=;
      do n=2 to 10;
         f=sum(f, lag(f));
         put n=f=;
      end;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Fibonacci Sequence
n=1 f=1
n=2 f=1
n=3 f=2
n=4 f=3
n=5 f=5
n=6 f=8
n=7 f=13
n=8 f=21
n=9 f=34
n=10 f=55
```

Example 3: Using Expressions for the LAG Function Argument

The following program uses an expression that creates a data set that contains the values for X, Y, and Z. LAG dequeues the previous values of the expression and enqueues the current value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data one (overwrite=yes);
   declare int x y z;
   method run();
      do x=1 to 6;
         y=lag1(x+10);
         z=lag2(x);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=one;
   title LAG Output: Using an Expression;
run;
```

Output 7.12 *Output from the LAG Function: Using an Expression*

LAG Output: Using an Expression

Obs	x	y	z
1	1	.	.
2	2	11	.
3	3	12	1
4	4	13	2
5	5	14	3
6	6	15	4

Example 4: Generating a Lag Queue for Array Elements

The following program generates a separate queue for each index into the array.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x[2];
   method init();
      dcl int i j k y;
      y=1;
      i=1;
      j=1;
      do while (y > 0 or missing(y));
         x[1]=i * 3;
         x[2]=i * 7;
         if i < 9 or i > 15 then
            k=1;
         else
         k=2;
         y=lag(x[k]);
         put i=y=;
         i=i + 1;
         j=1 - j;
         if (i > 20) then
            y=-1;
      end;
end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
i=1 y=
i=2 y=3
i=3 y=6
i=4 y=9
i=5 y=12
i=6 y=15
i=7 y=18
i=8 y=21
i=9 y=
i=10 y=63
i=11 y=70
i=12 y=77
i=13 y=84
i=14 y=91
i=15 y=98
i=16 y=24
i=17 y=48
i=18 y=51
i=19 y=54
i=20 y=57
```

LARGEST Function

Returns the *k*th largest non-null or nonmissing value.

Category: Descriptive Statistics

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

LARGEST(*k*, *expression* [, ...*expression*])

Required Arguments

k

specifies any valid expression that evaluates to a numeric value that represents the largest value to return. For example, if *k* is 2, the LARGEST function returns the second largest value from the list of expressions.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression

specifies any valid expression that evaluates to a numeric value and that is to be searched.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If *k* is null or missing, less than zero, or greater than the number of values, the result is a null or missing value. Otherwise, if *k* is greater than the number of non-null or nonmissing values, the result is a null or missing value.

Example

The following program illustrates the LARGEST function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double k largest1 largest2 largest3 largest4;
   method run();
      k=1;
      largest1=largest(k, 456, 789, .Q, 123);
      k=2;
      largest2=largest(k, 456, 789, .Q, 123);
      k=3;
      largest3=largest(k, 456, 789, .Q, 123);
      k=4;
      largest4=largest(k, 456, 789, .Q, 123);
      put largest1=;
      put largest2=;
      put largest3=;
      put largest4=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
largest1=789
largest2=456
largest3=123
largest4=.
```

See Also

Functions:

- “ORDINAL Function” on page 926
- “PCTL Function” on page 927
- “SMALLEST Function” on page 1157

LBOUND Function

Returns the lower bound of an array.

Category: Array

Returned data type: INTEGER

Syntax

LBOUND(*array-name*[, *bound-n*])

Required Argument

array-name
specifies the name of a temporary or a variable array.

Optional Argument

bound-n
is a numeric constant, variable, or expression that specifies the dimension, in a multidimensional array, for which you want to know the lower bound.

If no *bound-n* value is specified, the LBOUND function returns the lower bound of the first dimension of the array.

Bound-n evaluates to an integral value.

Details

The LBOUND function returns the lower bound of a one-dimensional array, or the lower bound of a specified dimension of a multidimensional array. LBOUND and HBOUND can be used together to return the values of the lower and upper bounds of an array dimension.

If the LBOUND function is called with a dimension value that is outside the dimension of the array, then a run-time error occurs and the function returns a NULL integer value.

Comparisons

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
- LBOUND returns the value of the lower bound of an array dimension.
- NDIMS returns the number of dimensions in an array.

Examples

Example 1: One-Dimensional Array

The following program shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions for a one-dimensional array:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method init();
      declare char(15) a1[4];
      declare double i a2[2,3,4] sum numelems j k;
      a1 := ('red' 'yellow' 'green' 'blue');
      a2 := (24*2.0);
      do i = 1 to dim(a1);
         put a1[i];
      end;
      numelems = 0;
      do i = 1 to ndims(a2);
         numelems = numelems + dim(a2, i);
      end;
      sum = 0;
      do i = lbound(a2, 1) to hbound(a2, 1);
        do j = lbound(a2, 2) to hbound(a2, 2);
          do k = lbound(a2, 3) to hbound(a2, 3);
             sum = sum + a2[i,j,k];
          end;
        end;
      end;
      put sum=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
red
yellow
green
blue
sum=48
```

Example 2: Multi-dimensional Array

The following program shows how to use the LBOUND array function for a multi-dimensional array:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data test(overwrite=yes);
   dcl double x1 x2 x3;
   vararray double mult[2:6, 4:13, 2] mult1-mult100;
   method run();
      x1=LBOUND(MULT,1);
      x2=LBOUND(MULT,2);
      x3=LBOUND(MULT,3);
      put x1= x2= x3=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=2 x2=4 x3=1
```

- “NDIMS Function” on page 878

LCM Function

Returns the least common multiple for a set of whole numbers.

Category:	Mathematical
Returned data type:	DOUBLE
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

LCM(*expression*-1, *expression*-2 [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a whole number.

Requirement	At least two arguments are required.
Data type	DOUBLE
Note	If any expression evaluates to zero, an error occurs and a missing value is returned.
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The least common multiple is the smallest number that two or more numbers divide into evenly.

Example

The following program illustrates the LCM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=lcm(10, 15);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
30
```

See Also

Functions:

- "GCD Function" on page 678

LCOMB Function

Computes the logarithm of the COMB function, which is the logarithm of the number of combinations of *n* objects taken *r* at a time.

Category: Combinatorial

Returned data type: DOUBLE

Syntax

LCOMB(*n*, *r*)

Required Arguments

n

is a nonnegative whole number that represents the total number of elements from which the sample is chosen.

r

is a nonnegative whole number that represents the number of chosen elements.

Restriction $r \leq n$

Comparisons

The LCOMB function computes the logarithm of the COMB function.

Example

The following program illustrates the LCOMB function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y;
   method init();
      x=lcomb(5000,500);
      y=lcomb(100,10);
      put x= y=;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1621.44113611415
30.4823233622786
```

See Also

Functions:

- "COMB Function" on page 431

LEFT Function

Left aligns a character expression.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

LEFT(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

LEFT returns a character string with leading blanks moved to the end of the value.

Example

The following program illustrates the LEFT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(12) a;
   method run();
      a=left(' END-OF-YEAR');
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
END-OF-YEAR
```

See Also

Functions:

- “COMPRESS Function” on page 456
- “RIGHT Function” on page 1098
- “STRIP Function” on page 1179
- “TRIM Function” on page 1230

LENGTH Function

Returns the length of a character string, excluding trailing blanks, in characters.

Category:	Character
Alias:	LENGTHN
Returned data type:	BIGINT, INTEGER

Syntax

LENGTH(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The LENGTH function returns an integer that represents the position of the rightmost non-blank character or number in *expression*. If the value of *expression* is a blank-filled or an empty string, LENGTH returns a value of 0. If *expression* is a numeric constant, variable, or expression (either initialized or uninitialized), SAS automatically converts the numeric value to a right-justified character string.

Comparisons

- The LENGTH function returns the length of a character string, excluding trailing blanks, whereas the LENGTHC function returns the length of a character string, including trailing blanks. LENGTH always returns a value that is less than or equal to the value returned by LENGTHC.
- The LENGTH function returns the length of a character string in characters, excluding trailing blanks, whereas the LENGTHM function returns the amount of memory in bytes that is allocated for a character string. LENGTH always returns a value that is less than or equal to the value returned by LENGTHM. However, with an expression argument, LENGHTM always returns a null value, whereas LENGTH returns the length, in characters, of the character value.

Example

The following program illustrates the LENGTH function. The data type for **g** is converted to NCHAR with a value of 20943 whose length is 5. The data type for **d** and **e**, the null or missing value (.), is converted from DOUBLE to NCHAR with a value of . whose length is 1.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double c d e f g;
   method run();
      c=length('ABDCEF    ');
```

```
        d=length('   ');
        e=length(.);
        g=date();
        f=length(g);
        put c;
        put d;
        put e;
        put f;
     end;
  enddata;
  run;
  quit;
```

SAS writes the following output to the log:

```
6
0
1
5
```

See Also

Functions:

- "LENGTHC Function" on page 819
- "LENGTHM Function" on page 822

LENGTHC Function

Returns the length of a character string, including trailing blanks, in characters.

Category:	Character
Returned data type:	BIGINT, INTEGER

Syntax

LENGTHC(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

For fixed-length variables, LENGTHC returns the character length of a character string, including trailing blanks. If *expression* is a fixed-length variable, the value returned by LENGTHC is equal to the declared length of the variable. If *expression* is a varying-length variable, the value returned by LENGTHC is less than or equal to the declared length of the variable. If the value of *expression* is missing and contains blanks, LENGTHC returns the number of blanks in *expression*. If *expression* is a numeric expression (either initialized or uninitialized), SAS automatically converts the numeric value to a right-justified character string.

Comparisons

- The LENGTHC function returns the length of a character string, including trailing blanks, whereas the LENGTH function returns the length of a character string, excluding trailing blanks. LENGTHC always returns a value that is greater than or equal to the value returned by LENGTH.
- The LENGTHC function returns the length of a character string, including trailing blanks, whereas the LENGTHM function returns the amount of memory in bytes that is allocated for a character string. For fixed-length character strings, LENGTHC and LENGTHM always return the same value. For varying-length character strings, LENGTHC always returns a value that is less than or equal to the value returned by LENGTHM. However, with an expression argument, LENGHTM always returns a null value, whereas LENGTHC returns the length, in characters, of the character value.

Examples

Example 1: LENGTHC Returns Actual Length of String

The following program illustrates the LENGTHC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double c;
   method run();
      c=lengthc('string with trailing blanks     ');
      put c;
   end;
enddata;
```

```
run;
quit;
```

SAS writes the following output to the log.

```
32
```

Example 2: LENGTHC with Varying-Length String

The following program illustrates the LENGTHC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test2 (overwrite=yes);
   dcl varchar(25) string;
   dcl double a;
   method run();
      string='The power to know.  ';
      a=lengthc(string);
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
20
```

Example 3: LENGTHC with Fixed-Length String

The following program illustrates the LENGTHC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test2 (overwrite=yes);
   dcl char(25) string;
   dcl double b;
   method run();
      string='The power to know.  ';
      b=lengthc(string);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
25
```

Example 4: LENGTHC with a Zero-Length String

The following program illustrates the LENGTHC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test2 (overwrite=yes);
   dcl double d;
   method run();
      d=lengthc('');
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
0
```

Example 5: LENGTHC with a Blank String

The following program illustrates the LENGTHC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test2 (overwrite=yes);
   dcl double d;
   method run();
      d=lengthc(' ');
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1
```

See Also

Functions:

- “LENGTH Function” on page 817
- “LENGTHM Function” on page 822

LENGTHM Function

Returns the amount of memory, in bytes, that could or might be allocated for a character string.

Category: Character

Returned data type: BIGINT, INTEGER

Syntax

LENGTHM(*variable*)

Required Argument

variable
specifies any valid string variable. An expression that evaluates or can be coerced to a string value is an invalid argument.

Restriction: Only variable arguments are allowed. Expressions and literals are not valid and return a null byte length

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Details

The LENGTHM function returns the maximum amount of memory, in bytes, that might be allocated for a character variable. This is true regardless of the character data type qualifiers such as NATIONAL, VARYING, CHARACTER SET, and so on.

The value returned by the LENGTHM function is independent of the current value stored in the variable and might be greater than the currently allocated byte length of the variable. This is true for both fixed-length and varying-length character variables. For example, if you have a CHAR(100) CHARACTER SET UTF-8 variable or a VARCHAR(100) CHARACTER SET UTF-8 variable, the LENGTHM function returns 400 bytes regardless of the value stored in the variable.

For a literal or an expression, the value returned by the LENGTHM function is a null byte length and a warning is issued that the argument is invalid for the function.

Comparisons

The LENGTHM function returns the amount of memory in bytes that is allocated for a character string, whereas the LENGTH and LENGTHC functions return the length, in characters, of a character value. With a variable argument, LENGTHM always returns a value that is greater than or equal to the values returned by LENGTH and LENGTHC. With an expression argument, LENGHTM always returns a null value, whereas LENGTH and LENGTHC return the length, in characters, of the character value.

Examples

Example 1: LENGHTM with Latin1 Character Set

The following program illustrates the LENGTHM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(25) character set latin1 string;
   dcl double a;
   method run();
      string='The power to know.   ';
      a=lengthm(string);
      put a;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
25
```

Example 2: LENGTHM with UTF-8 Character Set

The following program illustrates the LENGTHM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl varchar(15) character set utf8 a;
   dcl double b;
   method run();
      a='ABCDEF     ';
      b=lengthm(a);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
60
```

See Also

- “LENGTHC Function” on page 819

LFACT Function

Computes the logarithm of the FACT (factorial) function.

Category: Combinatorial

Returned data type: DOUBLE

Syntax

LFACT(*n*)

Required Argument

n
is a whole number that represents the total number of elements from which the sample is chosen.

Details

The LFACT function computes the logarithm of the FACT function.

Example

The following program illustrates the LFACT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y ;
   method init();
      x=lfact(5000);
      y=lfact(100);
```

```
        put x=   y=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=37591.1435088767 y=363.739375555563
```

See Also

Functions:

- "FACT Function" on page 537

LGAMMA Function

Returns the natural logarithm of the Gamma function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

LGAMMA(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: Must be a positive number.

Data type: DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the LGAMMA function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a;
   method run();
      a=lgamma(2);
      put a=;
      a=lgamma(1.5);
      put a=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=0
a=-0.12078223763524
```

LOG Function

Returns the natural logarithm (base e) of a numeric value expression.

Category: Mathematical

Returned data type: DOUBLE

Syntax

LOG(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: Must be a positive number.

Data type: DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the LOG function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b;
   method run();
      a=log(1.0);
      b=log(10.0);
      put a=;
      put b=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=0
b=2.30258509299404
```

See Also

Functions:

- “LOG10 Function” on page 828
- “LOG2 Function” on page 831

LOG10 Function

Returns the base-10 logarithm of a numeric value expression.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

LOG10(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement Must be a positive number.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the LOG10 function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b;
   method run();
      a=log10(1.0);
      b=log10(10.0);
      put a=;
      put b=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=0
b=1
```

See Also

Functions:

- "LOG Function" on page 827
- "LOG2 Function" on page 831

LOG1PX Function

Returns the log of 1 plus the argument.

Category: Mathematical

Returned data type: DOUBLE

Syntax

LOG1PX(*x*)

Required Argument

x

specifies a numeric variable, constant, or expression.

Data type DOUBLE

Details

The LOG1PX function computes the log of 1 plus the argument. The LOG1PX function is mathematically defined by the following equation, where –1 < x:

$$LOG1PX(x) = log(1 + x)$$

When x is close to 0, `LOG1PX(x)` can be more accurate than `LOG(1+x)`.

Examples

Example 1: Computing the Log with the LOG1PX Function

The following program computes the log of 1 plus the value 0.5.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=log1px(0.5);
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0.40546510810816
```

Example 2: Comparing the LOG1PX Function with the LOG Function

In the following program, the value of X is computed by using the LOG1PX function. The value of Y is computed by using the LOG function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method run();
      x=log1px(1.e-5);
      put x= hex16.;
      y=log(1+1.e-5);
      put y= hex16.;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=3EE4F8AEA9AE7317
y=3EE4F8AEA9AF0A25
```

See Also

Functions:

- “LOG Function” on page 827

LOG2 Function

Returns the base 2 logarithm of a numeric value expression.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

LOG2(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement	Must be a positive number.
Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the LOG2 function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a;
   method run();
      a=log2(8.0);
      put a=;
      a=log2(4);
      put a=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=3
a=2
```

See Also

Functions:

- "LOG Function" on page 827
- "LOG10 Function" on page 828

LOGBETA Function

Returns the logarithm of the beta function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

LOGBETA(*a*, *b*)

Required Arguments

a

is the first shape parameter, where *a*>0.

Data type DOUBLE

b

is the second shape parameter, where *b*>0.

Data type DOUBLE

Details

The LOGBETA function is mathematically given by the equation

$$log(\beta(a,b)) = log(\Gamma(a)) + log(\Gamma(b)) - log(\Gamma(a+b))$$

In the equation, $\Gamma(.)$ is the gamma function.

If the expression cannot be computed, LOGBETA returns a missing value.

Example

The following DS2 program computes the logarithm of the beta function. The first shape parameter is 5, and the second shape parameter is 3.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double y;
   method run();
      y=logbeta(5,3);
      put y=;
   end;
enddata;
run;
```

```
quit;
```

The following line is written to the SAS log.

```
y=-4.65396035015752
```

See Also

Functions:

- “BETA Function” on page 322

LOGCDF Function

Returns the logarithm of a left cumulative distribution function.

Category: Probability

See: “CDF Function” on page 362

Syntax

LOGCDF(*'distribution'*, *quantile* [, *parameter-1*, ..., *parameter-k*])

Required Arguments

distribution
is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the LOGCDF distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'

Distribution	Argument
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL'|'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD'|'IGAUSS'
Weibull	'WEIBULL'

Note: Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

quantile
is a numeric variable, constant, or expression that specifies the value of a random variable.

Data type DOUBLE

Optional Argument

parameter-1, ..., parameter-k
are optional *shape*, *location*, or *scale* parameters appropriate for the specific distribution.

Data type DOUBLE

Details

The LOGCDF function computes the logarithm of a left cumulative distribution function (logarithm of the left side) from various continuous and discrete distributions. For more information, see the individual distributions in the table above.

For more information about the distributions that are listed in the table, see "CDF Function" on page 362.

LOGISTIC Function

Returns the logistic transformation of the argument.

Category: Mathematical

Syntax

LOGISTIC(*argument*)

Required Argument

argument
is a numeric variable, constant, or expression that specifies the value of a numeric random variable. When *argument* is a missing or null value, the LOGISTIC function returns a missing or null value.

Details

The LOGISTIC function returns the logistic transformation of an argument. It is typically used to convert a log odds value to a value on the probability scale. The function is mathematically expressed by the following equation:

$$logistic=\frac{e^x}{1+e^x}$$

If the argument contains a missing value, then the LOGISTIC function returns a missing or null value.

Example

The following program illustrates the LOGISTIC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b;
   method run();
      a=logistic(.5);
      b=logistic(7.3);
      put  'a= ' a;
      put 'b=' b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=  0.62245933120185
b= 0.99932491726936
```

LOGPDF Function

Computes the logarithm of the probability density (mass) function from various continuous and discrete distributions.

Category: Probability

Alias: LOGPMF

See: "PDF Function" on page 929

Syntax

LOGPDF(*'distribution'*, *quantile*, *parameter-1, ..., parameter-k*)

Required Arguments

distribution
is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the LOGPDF distribution functions are identical to those of the corresponding PDF distribution functions.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'

Distribution	Argument
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL'|'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD'|'IGAUSS'
Weibull	'WEIBULL'

Note: Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

quantile
is a numeric constant, variable, or expression that specifies the value of a random variable.

Data type DOUBLE

parameter-1, ..., parameter-k
are optional *shape*, *location*, or *scale* parameters appropriate for the specific distribution.

Data type DOUBLE

Details

The LOGPDF function computes the logarithm of the probability density (mass) function from various continuous and discrete distributions. For more information, see the individual distributions in the table above.

For more information about the distributions that are listed in the table, see "PDF Function" on page 929.

LOGSDF Function

Returns the logarithm of a survival function.

Category: Probability

See: "SDF Function" on page 1133

Syntax

LOGSDF(*'distribution'*, *quantile*, *parameter-1, ..., parameter-k*)

Required Arguments

distribution
is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the LOGSDF distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL'|'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'

Distribution	Argument
Wald (inverse Gaussian)	'WALD' | 'IGAUSS'
Weibull	'WEIBULL'

Note: Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

quantile
is a numeric constant, variable, or expression that specifies the value of a random variable.

Data type DOUBLE

parameter-1, ..., parameter-k
are optional *shape*, *location*, or *scale* parameters appropriate for the specific distribution.

Data type DOUBLE

Details

The LOGSDF function computes the logarithm of the survival function from various continuous and discrete distributions. For more information, see "SDF Function" on page 1133.

LOWCASE Function

Converts all letters in a character expression to lowercase.

Category:	Character
Alias:	LOWER
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

LOWCASE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Requirement	Literal character expressions must be enclosed in single quotation marks.
Data type	CHAR, NCHAR, NVARCHAR, VARCHAR
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The LOWCASE function copies a character expression, converts all uppercase letters to lowercase letters, and returns the altered value as a result.

Comparisons

The UPCASE function converts all letters in an argument to uppercase letters. The LOWCASE function converts all letters in an argument to lowercase letters.

Example

The following program illustrates the LOWCASE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(12) x;
   method run();
      x=lowcase('INTRODUCTION');
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
introduction
```

See Also

Functions:

- "UPCASE Function" on page 1237

LPERM Function

Computes the logarithm of the number of permutations of n objects, and can include r number of elements.

Category: Combinatorial

Returned data type: DOUBLE

Syntax

LPERM (*n* [, *r*])

Required Argument

n

represents the total number of elements from which the sample is chosen.

Data type INTEGER

Optional Argument

r

represents the number of chosen elements. If *r* is omitted, the function returns the factorial of *n*.

Restriction *n*<=*r*

Data type INTEGER

Details

The LPERM function computes the logarithm of the PERM function.

Example

The following program illustrates the LPERM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method run();
      x=lperm(5000,500);
      y=lperm(100,10);
      put x= y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
x=4232.77159457431 y=45.5867359353541
```

See Also

Functions:

- “PERM Function” on page 981

MAD Function

Returns the median absolute deviation from the median.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

MAD(*expression-1*[, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value of which the median absolute deviation from the median is to be computed.

Data type DOUBLE

Details

If all arguments have missing or null values, the result is a missing or null value. Otherwise, the result is the median absolute deviation from the median of the nonmissing or non-null values. The formula for the median is the same as the one that is used in the UNIVARIATE procedure. For more information, see Base SAS Procedures Guide: Statistical Procedures.

Example

The following program illustrates the MAD function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double c;
   method run();
      c=mad(2, 4, 1, 3, 5, 999999);
      put c;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1.5
```

See Also

MARGRCLPRC Function

Calculates call prices for European options on stocks, based on the Margrabe model.

Category: Financial

Returned data type: DOUBLE

Syntax

MARGRCLPRC(*X*$_1$, *t*, *X*$_2$, *sigma1*, *sigma2*, *rho12*)

Required Arguments

***X*$_1$**

is a nonmissing, positive value that specifies the price of the first asset.

Requirement: Specify X_1 and X_2 in the same units.

Data type: DOUBLE

t

is a nonmissing value that specifies the time to expiration, in years.

Data type: DOUBLE

***X*$_2$**

is a nonmissing, positive value that specifies the price of the second asset.

Requirement Specify X_2 and X_1 in the same units.

Data type DOUBLE

sigma1
is a nonmissing, positive fraction that specifies the volatility of the first asset.

Data type DOUBLE

sigma2
is a nonmissing, positive fraction that specifies the volatility of the second asset.

Data type DOUBLE

rho12
specifies the correlation between the first and second assets. See *SAS DS2 Language Reference* for more information.

specifies the correlation between the first and second assets, $\rho_{x_1x_2}$.

Range between –1 and 1

Data type DOUBLE

Details

The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. The function is based on the following relationship:

$$\text{CALL} = X_1 N(d_1) - X_2 N(d_2)$$

Arguments

X_1
specifies the price of the first asset.

X_2
specifies the price of the second asset.

N
specifies the cumulative normal density function.

$$d_1 = \frac{\left(\ln\left(\frac{N_1}{N_2}\right) + \left(\frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$d_2 = d_1 - \sigma\sqrt{t}$$

$$\sigma^2 = \sigma_{x_1}^2 + \sigma_{x_2}^2 - 2\rho_{x_1,x_2}\sigma_{x_1}\sigma_{x_2}$$

The following arguments apply to the preceding equation:

t
specifies the time to expiration.

$\sigma_{x_1}^2$
specifies the variance of the first asset.

$\sigma_{x_2}^2$
specifies the variance of the second asset.

σ_{x_1}
specifies the volatility of the first asset.

σ_{x_2}
specifies the volatility of the second asset.

ρ_{x_1, x_2}
specifies the correlation between the first and second assets.

For the special case of *t*=0, the following equation is true:

$$\text{CALL} = \max((X_1 - X_2), 0)$$

Note: This function assumes that there are no dividends from the two assets.

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. These functions return a scalar value.

Example

The following program illustrates the MARGRCLPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b;
   method run();
      a=margrclprc(15, .5, 13, .06, .05, 1);
      put a;
      b=margrclprc(2, .25, 1, .3, .2, 1);
      put b;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
2
1
```

MARGRPTPRC Function

Calculates put prices for European options on stocks, based on the Margrabe model.

Category: Financial

Returned data type: DOUBLE

Syntax

MARGRPTPRC(*X*$_1$, *t*, *X*$_2$, *sigma1*, *sigma2*, *rho12*)

Required Arguments

***X*$_1$**

is a nonmissing, positive value that specifies the price of the first asset.

Requirement: Specify X_1 and X_2 in the same units.

Data type: DOUBLE

t

is a nonmissing value that specifies the time to expiration, in years.

Data type: DOUBLE

***X*$_2$**

is a nonmissing, positive value that specifies the price of the second asset.

Requirement: Specify X_2 and X_1 in the same units.

Data type DOUBLE

sigma1
is a nonmissing, positive fraction that specifies the volatility of the first asset.

Data type DOUBLE

sigma2
is a nonmissing, positive fraction that specifies the volatility of the second asset.

Data type DOUBLE

rho12
specifies the correlation between the first and second assets. See *SAS DS2 Language Reference* for more information.

specifies the correlation between the first and second assets, $\rho_{x_1 y_1}$.

Range between –1 and 1

Data type DOUBLE

Details

The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. The function is based on the following relationship:

$$\text{PUT} = X_2 N(pd_1) - X_1 N(pd_2)$$

Arguments

X_1
specifies the price of the first asset.

X_2
specifies the price of the second asset.

N
specifies the cumulative normal density function.

$$pd_1 = \frac{\left(\ln\left(\frac{N_1}{N_2}\right) + \left(\frac{\sigma^2}{2}\right)t\right)}{\sigma\sqrt{t}}$$

$$pd_2 = pd_1 - \sigma\sqrt{t}$$

$$\sigma^2 = \sigma_{x_1}^2 + \sigma_{x_2}^2 - 2\rho_{x_1, x_2}\sigma_{x_1}\sigma_{x_2}$$

The following arguments apply to the preceding equation:

`t`
is a nonmissing value that specifies the time to expiration, in years.

σ_{x1}^2
specifies the variance of the first asset.

σ_{x2}^2
specifies the variance of the second asset.

σ_{x1}
specifies the volatility of the first asset.

σ_{x2}
specifies the volatility of the second asset.

$\rho_{x1,\,x2}$
specifies the correlation between the first and second assets.

To view the corresponding CALL relationship, see the "MARGRCLPRC Function" on page 847.

For the special case of *t*=0, the following equation is true:

$$\text{PUT} = \max((X_2 - X_1), 0)$$

Note: This function assumes that there are no dividends from the two assets.

For information about the basics of pricing, see "Using Pricing Functions" in *SAS Functions and CALL Routines: Reference*.

Comparisons

The MARGRPTPRC function calculates the put price for European options on stocks, based on the Margrabe model. The MARGRCLPRC function calculates the call price for European options on stocks, based on the Margrabe model. These functions return a scalar value.

Example

The following program illustrates the MARGRPTPRC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b;
   method run();
      a=margrptprc(2, .25, 3, .06, .2, 1);
      put a;
      b=margrptprc(3, .25, 4, .05, .3, 1);
      put b;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1.00000000009729
1.00157624907711
```

Functions:

- "MARGRCLPRC Function" on page 847

MAX Function

Returns the largest value from a list of arguments.

Category: Descriptive Statistics

Returned data type: BIGINT, DECIMAL, DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

MAX(*expression-1, expression-2* [, ...*expression-n*])

Required Argument

expression
is any valid expression that evaluates to a numeric value.

Requirement: At least two arguments are required.

Data type: BIGINT, DECIMAL, DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Comparisons

The MAX function returns the largest value from a list of arguments. The MAX operator (<>) returns the largest of two operands.

The MAX function returns a null or missing value only if all arguments are null or missing. The MAX operator (<>) returns a null or missing value only if both operands are null or missing. In this case, it returns the value of the operand that is higher in the sort order for null or missing values.

Example

The following program illustrates the MAX function:

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=max(8, 3);
      put x;
      x=max(2, 6, .);
      put x;
      x=max(2, -3, 1, -1);
      put x;
      x=max(3, ., -3);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
8
6
2
3
```

MD5 Function

Returns the result of the message digest of a specified string in binary format.

Category: Character

Restriction: When you are using character arguments, MD5 accepts CHAR with any character set, including the NATIONAL character set (NCHAR).

Returned data type: BINARY

Syntax

MD5(*string*)

Required Argument

string
specifies a character constant, variable, or expression.

Data type: BINARY, CHAR

Tips: Enclose a literal string of characters in single quotation marks.

For scalar character variable arguments, the initial character set encoding that is specified in the DECLARE statement is used to transcode the variable before it is passed to the MD5 function. For binary arguments, the binary value is treated as a character string and the session encoding is used to transcode the value it is passed to the MD5 function.

Details

The Basics

The MD5 function converts a string, based on the MD5 algorithm, into a 128-bit hash value. This hash value is referred to as a *message digest* (digital signature), and it is nearly unique for each string that is passed to the function.

The MD5 function does not format its own output. Use the $BINARY*w*. or the $HEX*w*. formats to view readable results.

The Message Digest Algorithm

A message digest results from manipulating and compacting an arbitrarily long stream of binary data. An ideal message digest algorithm never generates the same result for two different sets of input. However, generating such a unique result would require a message digest as long as the input itself. Therefore, MD5 generates a message digest of modest size (16 bytes), created with an algorithm that is designed to make a nearly unique result.

Using the MD5 Function

You can use the MD5 function to track changes in your tables. The MD5 function can generate a digest of a set of column values in a record in a table. This digest could be treated as the signature of the record, and be used to keep track of changes that are made to the record. If the digest from the new record matches the existing digest of a record in a table, then the two records are the same. If the digest is different, then a column value in the record has changed. The new changed record could then be added to the table along with a new surrogate key because it represents a change to an existing keyed value.

The MD5 function can be useful when developing shell scripts or Perl programs for software installation, for file comparison, and for detection of file corruption and tampering.

You can also use the MD5 function to create a unique identifier for observations to be used as the key of a hash package. For more information, see "Using the Hash Package" in *SAS DS2 Programmer's Guide*.

Example

Here is an example of how to generate results that are returned by the MD5 function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method init();
   dcl binary(32) y z having format $hex32.;
      y = md5('abc');
      z = md5('access method');
      put y= ;
      put z= ;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
y=900150983CD24FB0D6963F7D28E17F72
z=53128C19421A8E0C7F6436D06A026537
```

MDY Function

Returns a SAS date value from month, day, and year values.

Category: Date and Time

Returned data type: DOUBLE

Syntax

MDY(*month*, *day*, *year*)

Required Arguments

month
specifies a numeric expression that represents a whole number from 1 through 12.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

day
specifies a numeric expression that represents a whole number from 1 through 31.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

year
specifies a numeric expression that represents a two-digit or four-digit year. The YEARCUTOFF= system option defines the year value for two-digit dates.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following programs illustrate the MDY function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double d m y;
   dcl double birthday having format mmddyy10.;
   method run();
       d=8; m=27; y=19;
       birthday= mdy(d,m,y);
       put birthday;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
08/27/2019
```

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test2 (overwrite=yes);
   dcl double d m y;
   dcl double anniversary having format date9.;
   method run();
       d=7; m=11; y=19;
       anniversary= mdy(d,m,y);
       put anniversary;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
11JUL2019
```

MEAN Function

Returns the arithmetic mean (average) of the non-null or nonmissing arguments.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

MEAN(*expression-1*[, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.

Data type: DOUBLE

See: “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Comparisons

The GEOMEAN function returns the geometric mean, the HARMEAN function returns the harmonic mean, whereas the MEAN function returns the arithmetic mean (average).

Example

The following program illustrates the MEAN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3;
```

```
      method run();
         x1=mean(2, ., ., 6);
         put x1;
         x2=mean(1, 2, 3, 2);
         put x2;
         x3=mean(of x1-x2);
         put x3;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log:

```
4
2
3
```

- “GEOMEANZ Function” on page 685
- “HARMEAN Function” on page 694
- “HARMEANZ Function” on page 696
- “MEDIAN Function” on page 860

MEDIAN Function

Returns the median value.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

MEDIAN(*expression-1*[, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The MEDIAN function returns the median of the nonmissing or nonnull values. If all arguments have missing or null values, the result is a missing or null value.

Note: The formula that is used in the MEDIAN function is the same as the formula that is used in PROC UNIVARIATE in Base SAS Procedures Guide: Statistical Procedures. For more information, see SAS Elementary Statistics Procedures.

Comparisons

The MEDIAN function returns the median of nonmissing or nonnull values, whereas the MEAN function returns the arithmetic mean (average).

Example

The following program illustrates the MEDIAN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x y;
   method run();
      x=median(2, 4, 1, 3);
      put x;
      y=median(5, 8, 0, 3, 4);
      put y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
2.5
4
```

See Also

Functions:

- “MEAN Function” on page 859

MIN Function

Returns the smallest value.

Category: Descriptive Statistics

Returned data type: BIGINT, DECIMAL, DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

MIN(*expression-1, expression-2* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least two arguments are required.

Data type: BIGINT, DECIMAL, DOUBLE

See: “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Details

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Comparisons

The MIN function returns the smallest value from a list of values. The MIN operator (><) returns the smallest value of two operands.

The MIN function returns a null or missing value only if all arguments are null or missing. The MIN operator returns a null or missing value only if either operand is null or missing. In this case, it returns the value of the operand that is lower in the sort order for null or missing values.

Example

The following program illustrates the MIN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x x1 x2 x3 x4 x5;
   method run();
      x=min(7,4);
      put x;
      x1=min(2, ., 6);
      put x1;
      x2=min(2, -3, 1, -1);
      put x2;
      x3=min(0, 4);
      put x3;
      x4=min(of x1-x3);
      put x4;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
4
2
-3
0
-3
```

MINUTE Function

Returns the minute from a SAS time or datetime value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

MINUTE(*time* | *datetime*)

Required Arguments

time
specifies any valid expression that represents a SAS time value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

datetime
specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The MINUTE function returns a whole number that represents a specific minute of the hour. MINUTE always returns a positive number in the range of 0 through 59. Null or missing values are ignored.

Example

The following programs illustrate the MINUTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double d;
   method init();
      d=minute(time());
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
38
```

```
proc ds2;
data test(overwrite=yes);
   dcl double m dt;
   dcl time t;
   method run();
      t=time '03:19:24';
      dt=to_double(t);
      m=minute(dt);
      put m;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
19
```

See Also

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Functions:

- "HOUR Function" on page 707
- "SECOND Function" on page 1139

MISSING Function

Returns a number that indicates whether the argument contains a missing value.

Category:	Special
Returned data type:	INTEGER
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

MISSING(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a value.

Data type: All data types

Note: If you are using SAS Federation Server, ANSI null values are translated to SAS missing values in FedSQL CALL invocations when the DS2_SASMISSING environment variable is set to TRUE.

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

- The MISSING function checks if a value is a null or missing value and returns a numeric result. If the argument does not contain a missing value, SAS returns a value of 0. If the argument contains a missing value, SAS returns a value of 1.
- In SAS mode, a blank-filled character value is defined to be the SAS missing value. In ANSI mode, a blank-filled character value is defined as nonmissing and non-null.
- In SAS mode, a DOUBLE value could be a SAS missing value (., .A through .Z). The other numeric types do not support SAS missing values.
- The MISSING function returns a 1 if a package instance does not exist. That is, the package variable is a missing package reference. The MISSING function returns a 0 if the package variable references a package instance.

Comparisons

The MISSING function can have only one argument. The NMISS function requires numeric arguments and returns the number of missing values in the list of arguments.

Note: Missing values and null values are treated differently in SAS mode versus ANSI mode. Missing and null values might be converted dependent on mode.

Examples

Example 1: Using the MISSING Function

The following program illustrates the MISSING function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl int a[3];
   dcl double i;
   method run();
      a[1]=2;
      a[2]=4;
      a[3]=.;
      do i = 1 to 3;
         if missing(a[i]) then put 'Missing';
            else put 'Not Missing';
      end;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
Not Missing
Not Missing
Missing
```

Example 2: MISSING Function with SAS Mode and ANSI Mode

This program illustrates how a DS2 program with a MISSING function can return different results based on mode.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(1) a[3];
   dcl double  b[3];
   dcl int c[3];
   dcl int i;
   method run();
      a := ('a', '', NULL);
      b := (1, ., NULL);
      c := (1, NULL, NULL);
      do i = 1 to 3;
         if (missing(a[i])) then put a[i]= 'missing';
            else put a[i]= 'not missing';
          if (missing(b[i])) then put b[i]= 'missing';
            else put b[i]= 'not missing';
          if (missing(c[i])) then put c[i]= 'missing';
            else put c[i]= 'not missing';
      end;
   end;
enddata;
run;
quit;
```

In SAS mode, the following lines are written to the SAS log.

```
a[1]=a not missing
b[1]=1 not missing
c[1]=1 not missing
a[2]=  missing
b[2]=. missing
c[2]= missing
a[3]=  missing
b[3]=. missing
c[3]= missing
```

In ANSI mode, the following lines are written to the SAS log.

```
a[1]=a not missing
b[1]=1 not missing
c[1]=1 not missing
a[2]=  not missing
b[2]= missing
c[2]= missing
a[3]= missing
b[3]= missing
c[3]= missing
```

- "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*

Functions:

- "CMISS Function" on page 420
- "NMISS Function" on page 882
- "N Function" on page 877
- "NULL Function" on page 921

MOD Function

Returns the remainder from the division of the first argument by the second argument, fuzzed to avoid most unexpected floating-point results.

Category:	Mathematical
Returned data type:	DOUBLE
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

MOD(*dividend-expression*, *divisor-expression*)

Required Arguments

dividend-expression
specifies a dividend that is any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

divisor-expression
specifies a divisor that is any valid expression that evaluates to a numeric value.

Restriction *divisor-expression* cannot be 0

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The MOD function returns the remainder from the division of *dividend-expression* by *divisor-expression*. When the result is nonzero, the result has the same sign as the first argument. The sign of the second argument is ignored.

The computation that is performed by the MOD function is exact if both of the following conditions are true:

- Both arguments are exact integers.
- All integers that are less than either argument have exact 8-byte floating-point representations.

If either of the above conditions is not true, a small amount of numerical error can occur in the floating-point computation. In this case, the following occurs.

- MOD returns zero if the remainder is very close to zero or very close to the value of the second argument.
- MOD returns a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more. In this case, SAS also writes an error message to the log.

Comparisons

Here are some comparisons between the MOD and MODZ functions:

- The MOD function performs extra computations, called fuzzing, to return an exact zero when the result would otherwise differ from zero because of numerical error.
- The MODZ function performs no fuzzing.
- Both the MOD and MODZ functions return a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more.

Example

The following program illustrates the MOD and MODZ functions:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3  xa xb xc having format 9.4;
   dcl double x4 xd having format 24.20;
   method run();
      x1=mod(10, 3);
      put x1=;
      xa=modz(10, 3);
      put xa=;
      x2=mod(.3, -.1);
      put x2=;
      xb=modz(.3, -.1);
      put xb=;
      x3=mod(1.7, .1);
      put x3=;
      xc=modz(1.7, .1);
      put xc=;
      x4=mod(.9, .3);
      put x4=;
      xd=modz(.9, .3);
      put xd=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=   1.0000
xa=   1.0000
x2=   0.0000
xb=   0.1000
x3=   0.0000
xc=   0.0000
x4=  0.00000000000000000000
xd=  0.00000000000000011102
```

MODZ Function

Returns the remainder from the division of the first argument by the second argument, using zero fuzzing.

Category: Mathematical

Returned data type: DOUBLE

Syntax

MODZ(*dividend-expression*, *divisor-expression*)

Required Arguments

dividend-expression
specifies a dividend that is any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

divisor-expression
specifies a divisor that is any valid expression that evaluates to a numeric value.

Restriction *divisor-expression* cannot be 0

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The MODZ function returns the remainder from the division of *dividend-expression* by *divisor-expression*. When the result is nonzero, the result has the same sign as the first argument. The sign of the second argument is ignored.

The computation that is performed by the MODZ function is exact if both of the following conditions are true:

- Both arguments are exact integers.
- All integers that are less than either argument have exact 8-byte floating-point representation.

If either of the above conditions is not true, a small amount of numerical error can occur in the floating-point computation. For example, when you use exact arithmetic and the result is zero, MODZ might return a very small positive value or a value slightly less than the second argument.

Comparisons

Here are some comparisons between the MODZ and MOD functions:

- The MODZ function performs no fuzzing.
- The MOD function performs fuzzing, to return an exact zero when the result would otherwise differ from zero because of numerical error.
- Both the MODZ and MOD functions return a null or missing value if the remainder cannot be computed to a precision of approximately three digits or more.

Example

The following statements illustrate the MOD and MODZ functions:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3  xa xb xc having format 9.4;
   dcl double x4 xd having format 24.20;
   method run();
      x1=mod(10, 3);
      put x1=;
      xa=modz(10, 3);
      put xa=;
      x2=mod(.3, -.1);
      put x2=;
      xb=modz(.3, -.1);
      put xb=;
```

```
        x3=mod(1.7, .1);
        put x3=;
        xc=modz(1.7, .1);
        put xc=;
        x4=mod(.9, .3);
        put x4=;
        xd=modz(.9, .3);
        put xd=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=   1.0000
xa=   1.0000
x2=   0.0000
xb=   0.1000
x3=   0.0000
xc=   0.0000
x4=  0.0000000000000000000
xd=  0.0000000000000011102
```

- “MOD Function” on page 868

MONTH Function

Returns a number that represents the month from a SAS date value.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

MONTH(*date*)

Required Argument

date

specifies any valid expression that represents a SAS date value.

Range 1–12

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the MONTH function when the month is March:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double d;
   method init();
      d=month(date());
      put d;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
3
```

The following program illustrates the MONTH function when the date is February 5, 2019:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double m dat;
   dcl date d;
   method run();
      d=date '2019-02-05';
      dat=to_double(d);
      m=month(dat);
      put m;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
2
```

- "YEAR Function" on page 1277

MORT Function

Returns amortization parameters.

Category:	Financial
Returned data type:	DOUBLE

Syntax

MORT(*a*, *p*, *r*, *n*)

Required Arguments

a

specifies any valid expression that evaluates to the initial amount.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

p

specifies any valid expression that evaluates to the periodic payment.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

r

specifies any valid expression that evaluates to the periodic interest rate that is expressed as a fraction.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

n

specifies any valid expression that evaluates to the number of compounding periods.

Range $n \geq 0$

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

Calculating Results

The MORT function returns the missing argument in the list of four arguments from an amortization calculation with a fixed interest rate that is compounded each period. The arguments are related by the following equation:

$$p = \frac{ar(1+r)^n}{(1+r)^n - 1}$$

One missing argument must be provided. The value is then calculated from the remaining three. No adjustment is made to convert the results to round numbers.

Restrictions in Calculating Results

The MORT function returns an invalid argument note to the SAS log and sets _ERROR_ to 1 if one of the following argument combinations is true:

- rate < –1 or n < 0
- principal <= 0 or payment <= 0 or n <= 0
- principal <= 0 or payment <= 0 or rate <= –1
- principal * rate > payment
- principal > payment * n

Example

In the following program, an amount of $50,000 is borrowed for 30 years at an annual interest rate of 10% compounded monthly.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
```

```
   dcl double payment;
   method run();
      payment=mort(50000, . , .10/12, 30*12);
      put payment;
   end;
enddata;
run;
quit;
```

The value that is returned is 438.79 (rounded). The second argument is set to missing, which indicates that the periodic payment is to be calculated. The 10% nominal annual rate has been converted to a monthly rate of 0.10/12. The rate is the fractional (not the percentage) interest rate per compounding period. The 30 years are converted to 360 months.

N Function

Returns the number of non-null or nonmissing numeric values.

Category: Special

Returned data type: INTEGER

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

N(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least one argument is required.

Data type: DECIMAL, DOUBLE, NUMERIC

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

Null values are converted to missing values and are counted as missing values.

Comparisons

The N function counts non-null and nonmissing values, whereas the NMISS function counts missing values. The N function requires numeric arguments.

Example

The following program illustrates the N function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3;
   method run();
      x1=n(1, 0,., 2, 5, .);
      x2=n(1, 2);
      x3=n(of x1-x2);
      put x1= x2= x3=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=4 x2=2 x3=2
```

See Also

Functions:

- “NMISS Function” on page 882

NDIMS Function

Returns the number of dimensions in an array.

Category:	Array
Returned data type:	INT

Syntax

NDIMS(*array-name*)

Required Argument

array-name
specifies the name of a temporary or a variable array.

Details

The NDIMS function returns the number of dimensions of a multidimensional array, or returns 1 for a one-dimensional array.

Comparisons

- DIM returns the number of elements in an array dimension.
- HBOUND returns the value of the upper bound of an array dimension.
- LBOUND returns the value of the lower bound of an array dimension.
- NDIMS returns the number of dimensions in an array.

Example

The following program shows how to use the DIM, HBOUND, LBOUND, and NDIMS array functions:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(15) a1[4];
   dcl double   a2[2,3,4] sum i j k numelems;
   method init();
      a1 := ('red' 'yellow' 'green' 'blue');
      a2 := (24*2.0);
      do i = 1 to dim(a1);
         put a1[i];
      end;
      numelems = 0;
      do i = 1 to ndims(a2);
         numelems = numelems + dim(a2, i);
      end;
      sum = 0;
      do i = lbound(a2, 1) to hbound(a2, 1);
```

```
            do j = lbound(a2, 2) to hbound(a2, 2);
              do k = lbound(a2, 3) to hbound(a2, 3);
                sum = sum + a2[i,j,k];
              end;
            end;
          end;
          put sum=;
        end;
    run;
    quit;
```

SAS writes the following output to the log:

```
red
yellow
green
blue
sum=48
```

See Also

- “LBOUND Function” on page 810

NETPV Function

Returns the net present value as a percent.

Category: Financial

Returned data type: DOUBLE

Syntax

NETPV(*r*, *freq*, *c0, c1, ..., cn*)

Required Arguments

r

is numeric, the interest rate over a specified base period of time expressed as a fraction.

Range *r* >= 0

Data type DOUBLE

freq
is numeric, the number of payments during the base period of time that is specified with the rate *r*.

Range *freq* > 0

Data type DOUBLE

Note The case *freq* = 0 is a flag to allow continuous discounting.

c0, c1 ,..., cn
are numeric cash flows that represent cash outlays (payments) or cash inflows (income) occurring at times 0, 1, ...n. These cash flows are assumed to be equally spaced, beginning-of-period values. Negative values represent payments, positive values represent income, and values of 0 represent no cash flow at a given time. The *c0* argument and the *c1* argument are required.

Data type DOUBLE

Details

The NETPV function returns the net present value at time 0 for the set of cash payments *c0*,*c1*, ...,*cn*, with a rate *r* over a specified base period of time. The argument *freq*>0 describes the number of payments that occur over the specified base period of time.

The net present value is given by the equation:

$$\mathrm{NETPV}(r, freq, c_0, c_1, ..., c_n) = \sum_{i=0}^{n} c_i x^i$$

The following relationship applies to the preceding equation:

$$x = \begin{cases} \frac{1}{(1+r)^{(1/freq)}} & freq > 0 \\ \varepsilon^{-r} & freq = 0 \end{cases}$$

Missing values in the payments are treated as 0 values. When *freq*>0, the rate *r* is the effective rate over the specified base period. To compute with a quarterly rate (the base period is three months) of 4% with monthly cash payments, set *freq* to 3 and set *r* to .04.

If *freq* is 0, continuous discounting is assumed. The base period is the time interval between two consecutive payments, and the rate *r* is a nominal rate.

To compute with a nominal annual interest rate of 11% discounted continuously with monthly payments, set *freq* to 0 and set *r* to .11/12.

Example

For an initial investment of $500 that returns biannual payments of $200, $300, and $400 over the succeeding 6 years and an annual discount rate of 10%, the net present value of the investment can be expressed as follows:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double value;
   method run();
      value=netpv(.10,.5,-500,200,300,400);
      put value;
   end;
enddata;
run;
quit;
```

The value that is returned is 95.982864829379.

See Also

Functions:

- “NPV Function” on page 920

NMISS Function

Returns the number of null and SAS missing numeric values.

Category:	Descriptive Statistics
Returned data type:	INTEGER
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

NMISS(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement	At least one argument is required.
Data type	DECIMAL, DOUBLE, NUMERIC
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

Null values are converted to SAS missing values and are counted as missing values.

Comparisons

The NMISS function returns the number of null or SAS missing values, whereas the N function returns the number of non-null and nonmissing values. NMISS requires numeric values and works with multiple numeric values, whereas MISSING works with only one value that can be either numeric or character.

Example

The following program illustrates the NMISS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x1 x2 x3;
   method run();
      x1=nmiss(1,0,.,2,5,.);
      x2=nmiss(1,0);
      x3=nmiss(of x1-x2);
      put x1= x2= x3=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=2 x2=0 x3=0
```

See Also

- "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*

Functions:

- "CMISS Function" on page 420

- "N Function" on page 877
- "NULL Function" on page 921

NOMRATE Function

Returns the nominal annual interest rate.

Category: Financial

Returned data type: DOUBLE

Syntax

NOMRATE(*compounding-interval*, *rate*)

Required Arguments

compounding-interval
is a SAS interval. This value represents how often the returned value is compounded.

Data type CHAR

rate
is numeric. *Rate* is the effective annual interest rate (expressed as a percentage) that is compounded at each interval.

Data type DOUBLE

Details

The NOMRATE function returns the nominal annual interest rate. NOMRATE computes the nominal annual interest rate that corresponds to an effective annual interest rate.

The following details apply to the NOMRATE function:

- The values for rates must be at least –99.
- In considering an effective interest rate and a compounding interval, if *compounding-interval* is 'CONTINUOUS', then the value that is returned by NOMRATE equals $\log_e(1+[rate/100])$.

  If *compounding-interval* is not 'CONTINUOUS', and *m* intervals occur in a year, the value that is returned by NOMRATE equals the following:

  $$m\left((1+\frac{rate}{100})^{\frac{1}{m}}-1\right)$$

- The following values are valid for *compounding-interval*:
  - 'CONTINUOUS'
  - 'DAY'
  - 'SEMIMONTH'
  - 'MONTH'
  - 'QUARTER'
  - 'SEMIYEAR'
  - 'YEAR'
- If the interval is 'DAY', then *m*=365.

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

- If an effective rate is 10% when compounded monthly, the corresponding nominal rate can be expressed as follows:

```
proc ds2;
data test(overwrite=yes);
   dcl double effective_rate1;
   method run();
      effective_rate1 = NOMRATE('MONTH', 10);
      put effective_rate1=;
   end;
enddata;
run;
quit;
```

  SAS writes the following output to the log.

```
effective_rate1=9.56896851468451
```

- If an effective rate is 10% when compounded quarterly, the corresponding nominal rate can be expressed as follows:

```
proc ds2;
data test(overwrite=yes);
```

```
   dcl double effective_rate2;
   method run();
      effective_rate2 = NOMRATE('QUARTER', 10);
      put effective_rate2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
effective_rate2=9.64547563377804
```

NOTALNUM Function

Searches a character string for a non-alphanumeric character, and returns the first character position at which the character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTALNUM('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTALNUM function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTALNUM function searches a string for the first occurrence of any character that is not a digit or an uppercase or lowercase letter. If such a character is found, NOTALNUM returns the position in the string of that character. If no such character is found, NOTALNUM returns a value of 0.

If you use only one argument, NOTALNUM begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTALNUM returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTALNUM function searches a character string for a non-alphanumeric character. The ANYALNUM function searches a character string for an alphanumeric character.

Example

The following program uses the NOTALNUM function to search a string from left to right for non-alphanumeric characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl nchar(16) string c;
   dcl double j i;
   method run();
      string='Next = Last + 1;';
      j=0;
```

```
            do until(j=0);
               j=notalnum(string, j+1);
               if j=0 then put 'The end';
               else do;
                  c=substr(string, j, 1);
                  put j= c=;
               end;
            end;
         end;
      enddata;
      run;
      quit;
```

SAS writes the following output to the log:

```
j=5 c=
j=6 c==
j=7 c=
j=12 c=
j=13 c=+
j=14 c=
j=16 c=;
The end
```

Functions:

- "ANYALNUM Function" on page 277

NOTALPHA Function

Searches a character string for a nonalphabetic character, and returns the first character position at which the character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

NOTALPHA('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTALPHA function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTALPHA function searches a string for the first occurrence of any character that is not an uppercase or lowercase letter. If such a character is found, NOTALPHA returns the position in the string of that character. If no such character is found, NOTALPHA returns a value of 0.

If you use only one argument, NOTALPHA begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTALPHA returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTALPHA function searches a character string for a nonalphabetic character. The ANYALPHA function searches a character string for an alphabetic character.

Examples

Example 1: Searching a String for Nonalphabetic Characters

The following program uses the NOTALPHA function to search a string from left to right for nonalphabetic characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notalpha(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=17 c=3
j=18 c=;
The end
```

Example 2: Identifying Control Characters By Using the NOTALPHA Function

You can execute the following program to show the control characters that are identified by the NOTALPHA function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
   dcl nchar(3) byte1 hex1;
   dcl double dec notalpha1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         notalpha1=notalpha(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

- “ANYALPHA Function” on page 280

NOTCNTRL Function

Searches a character string for a character that is not a control character, and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

NOTCNTRL('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTCNTRL function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTCNTRL function searches a string for the first occurrence of a character that is not a control character. If such a character is found, NOTCNTRL returns the position in the string of that character. If no such character is found, NOTCNTRL returns a value of 0.

If you use only one argument, NOTCNTRL begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTCNTRL returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTCNTRL function searches a character string for a character that is not a control character. The ANYCNTRL function searches a character string for a control character.

Example

You can execute the following program to show the control characters that are identified by the NOTCNTRL function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double dec notcntrl1;
   dcl char byte1 hex1;
   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec, hex2.);
         notcntrl1=notcntrl(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

- “ANYCNTRL Function” on page 283

NOTDIGIT Function

Searches a character string for any character that is not a digit, and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

NOTDIGIT('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTDIGIT function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTDIGIT function searches a string for the first occurrence of any character that is not a digit. If such a character is found, NOTDIGIT returns the position in the string of that character. If no such character is found, NOTDIGIT returns a value of 0.

If you use only one argument, NOTDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTDIGIT function searches a character string for any character that is not a digit. The ANYDIGIT function searches a character string for a digit.

Examples

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

Example 1: Searching for a Character That Is Not a Digit

The following program uses the NOTDIGIT function to search for a character that is not a digit.

```
proc ds2;
data _null_;
   dcl nchar(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notdigit(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=9 c=n
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=16 c=E
j=18 c=;
The end
```

Example 2: Submitting a Compressed Value to the NOTDIGIT Function

The following program shows how to submit compressed values to the NOTDIGIT function.

```
proc ds2;
data _null_;
   dcl char(5) x z;
   dcl double y;
   method run();
     x='1 ';
     y=notdigit(compress(x));
     put y=;
   end;
enddata;
run;
quit;
```

```
y=0
```

NOTFIRST Function

Searches a character string for an invalid first character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

NOTFIRST('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The NOTFIRST function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The NOTFIRST function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7. These characters are any except the underscore (_) and uppercase or lowercase English letters. If such a character is found, NOTFIRST returns the position in the string of that character. If no such character is found, NOTFIRST returns a value of 0.

If you use only one argument, NOTFIRST begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTFIRST returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTFIRST function searches a string for the first occurrence of any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7. The ANYFIRST function searches a string for the first occurrence of any character that is valid as the first character in a SAS variable name under VALIDVARNAME=V7.

Example

The following program uses the NOTFIRST function to search a string for any character that is not valid as the first character in a SAS variable name under VALIDVARNAME=V7.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl nchar(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notfirst(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=5 c=
j=6 c==
j=7 c=
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=17 c=3
j=18 c=;
The end
```

NOTGRAPH Function

Searches a character string for a non-graphical character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTGRAPH('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTGRAPH function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTGRAPH function searches a string for the first occurrence of a non-graphical character. A graphical character is defined as any printable character other than white space. If such a character is found, NOTGRAPH returns the position in the string of that character. If no such character is found, NOTGRAPH returns a value of 0.

If you use only one argument, NOTGRAPH begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTGRAPH returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTGRAPH function searches a character string for a non-graphical character. The ANYGRAPH function searches a character string for a graphical character.

Examples

Example 1: Searching a String for Non-Graphical Characters

The following program uses the NOTGRAPH function to search a string for a non-graphical character.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl nchar(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notgraph(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
j=5 c=
j=7 c=
j=11 c=
j=13 c=
The end
```

Example 2: Identifying Control Characters By Using the NOTGRAPH Function

You can execute the following program to show the control characters that are identified by the NOTGRAPH function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl nchar byte1 hex1;
   dcl double dec notgraph1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         notgraph1=notgraph(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

NOTLOWER Function

Searches a character string for a character that is not a lowercase letter, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTLOWER('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTLOWER function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTLOWER function searches a string for the first occurrence of any character that is not a lowercase letter. If such a character is found, NOTLOWER returns the position in the string of that character. If no such character is found, NOTLOWER returns a value of 0.

If you use only one argument, NOTLOWER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTLOWER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTLOWER function searches a character string for a character that is not a lowercase letter. The ANYLOWER function searches a character string for a lowercase letter.

Example

The following program uses the NOTLOWER function to search a string for any character that is not a lowercase letter.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl nchar(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notlower(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end
```

NOTNAME Function

Searches a character string for an invalid character in a SAS variable name under VALIDVARNAME=V7, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTNAME('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The NOTNAME function does not depend on the TRANTAB, ENCODING, or LOCALE system options.

The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7. These characters are any except underscore (_), digits, and uppercase or lowercase English letters. If such a character is found, NOTNAME returns the position in the string of that character. If no such character is found, NOTNAME returns a value of 0.

If you use only one argument, NOTNAME begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTNAME returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTNAME function searches a string for the first occurrence of any character that is not valid in a SAS variable name under VALIDVARNAME=V7. The ANYNAME function searches a string for the first occurrence of any character that is valid in a SAS variable name under VALIDVARNAME=V7.

Example

The following program uses the NOTNAME function to search a string for any character that is not valid in a SAS variable name under VALIDVARNAME=V7.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl nchar(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notname(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=5 c=
j=6 c==
j=7 c=
j=11 c=
j=12 c=+
j=13 c=
j=18 c=;
The end
```

NOTPRINT Function

Searches a character string for a nonprintable character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTPRINT('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTPRINT function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTPRINT function searches a string for the first occurrence of a non-printable character. If such a character is found, NOTPRINT returns the position in the string of that character. If no such character is found, NOTPRINT returns a value of 0.

If you use only one argument, NOTPRINT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTPRINT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTPRINT function searches a character string for a non-printable character. The ANYPRINT function searches a character string for a printable character.

Example

You can execute the following program to show the control characters that are identified by the NOTPRINT function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double dec notprint1;
   dcl nchar byte1 hex1;
   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec, hex2.);
         notprint1=notprint(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

NOTPUNCT Function

Searches a character string for a character that is not a punctuation character, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTPUNCT('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTPUNCT function depend directly on the translation table that is in effect (see "TRANTAB= System Option" in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTPUNCT function searches a string for the first occurrence of a character that is not a punctuation character. If such a character is found, NOTPUNCT returns the position in the string of that character. If no such character is found, NOTPUNCT returns a value of 0.

If you use only one argument, NOTPUNCT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTPUNCT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTPUNCT function searches a character string for a character that is not a punctuation character. The ANYPUNCT function searches a character string for a punctuation character.

Examples

Example 1: Searching a String for Characters That Are Not Punctuation Characters

The following program uses the NOTPUNCT function to search a string for characters that are not punctuation characters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notpunct(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=5 c=
j=6 c==
j=7 c=
j=9 c=n
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
The end
```

Example 2: Identifying Control Characters By Using the NOTPUNCT Function

You can execute the following program to show the control characters that are identified by the NOTPUNCT function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test/overwrite=yes;
   dcl nchar(3) byte1 hex1;
   dcl double dec notpunct1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         notpunct1=notpunct(byte1);
         output;
      end;
   end;
enddata;
run;
quit;

 proc print data=test;
 run;
quit;
```

Functions:

- “ANYPUNCT Function” on page 301

NOTSPACE Function

Searches a character string for a character that is not a whitespace character (blank, horizontal and vertical tab, carriage return, line feed, and form feed), and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTSPACE('*expression*'[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTSPACE function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in *SAS National Language Support*

(NLS): Reference Guide) and indirectly on the ENCODING and the LOCALE system options.

The NOTSPACE function searches a string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. If such a character is found, NOTSPACE returns the position in the string of that character. If no such character is found, NOTSPACE returns a value of 0.

If you use only one argument, NOTSPACE begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTSPACE returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTSPACE function searches a character string for the first occurrence of a character that is not a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed. The ANYSPACE function searches a character string for the first occurrence of a character that is a blank, horizontal tab, vertical tab, carriage return, line feed, or form feed.

Examples

Example 1: Searching a String for a Character That Is Not a Whitespace Character

The following program uses the NOTSPACE function to search a string for a character that is not a whitespace character.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
```

```
        j=0;
        do until(j=0);
           j=notspace(string, j+1);
           if j=0 then put 'The end';
           else do;
              c=substr(string, j, 1);
              put j= c=;
           end;
        end;
     end;
  enddata;
  run;
  quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=2 c=e
j=3 c=x
j=4 c=t
j=6 c==
j=8 c=_
j=9 c=n
j=10 c=_
j=12 c=+
j=14 c=1
j=15 c=2
j=16 c=E
j=17 c=3
j=18 c=;
The end
```

Example 2: Identifying Control Characters By Using the NOTSPACE Function

You can execute the following program to show the control characters that are identified by the NOTSPACE function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl nchar(3) byte1 hex1;
   dcl double dec notspace1;

   method run();
      do dec=0 to 255;
         byte1=byte(dec);
         hex1=put(dec,hex2.);
         notspace1=notspace(byte1);
         output;
      end;
   end;
enddata;
run;
quit;
```

- “ANYSPACE Function” on page 303

NOTUPPER Function

Searches a character string for a character that is not an uppercase letter, and returns the first character position at which that character is found.

Category: Character

Returned data type: DOUBLE

Syntax

NOTUPPER(*'expression'*[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The results of the NOTUPPER function depend directly on the translation table that is in effect (see “TRANTAB= System Option” in *SAS National Language Support (NLS): Reference Guide*) and indirectly on the ENCODING and the LOCALE system options.

The NOTUPPER function searches a string for the first occurrence of a character that is not an uppercase letter. If such a character is found, NOTUPPER returns the position in the string of that character. If no such character is found, NOTUPPER returns a value of 0.

If you use only one argument, NOTUPPER begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTUPPER returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTUPPER function searches a character string for a character that is not an uppercase letter. The ANYUPPER function searches a character string for an uppercase letter.

Example

The following program uses the NOTUPPER function to search a string for any character that is not an uppercase letter.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notupper(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
```

```
        end;
     end;
  enddata;
  run;
  quit;
```

SAS writes the following output to the log:

```
j=2 c=e
j=3 c=x
j=4 c=t
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=9 c=n
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=14 c=1
j=15 c=2
j=17 c=3
j=18 c=;
The end
```

See Also

Functions:

- “ANYUPPER Function” on page 306

NOTXDIGIT Function

Searches a character string for a character that is not a hexadecimal character, and returns the first character position at which that character is found.

Category:	Character
Returned data type:	DOUBLE

Syntax

NOTXDIGIT(‘*expression*’[, *start*])

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

start
specifies any valid expression that evaluates or can be coerced to a numeric value and specifies the character position at which the search should start and the direction in which to search.

Data type DOUBLE

Details

The NOTXDIGIT function searches a string for the first occurrence of any character that is not a digit or an uppercase or lowercase A, B, C, D, E, or F. If such a character is found, NOTXDIGIT returns the position in the string of that character. If no such character is found, NOTXDIGIT returns a value of 0.

If you use only one argument, NOTXDIGIT begins the search at the beginning of the string. If you use two arguments, the absolute value of the second argument, *start*, specifies the position at which to begin the search. The direction in which to search is determined in the following way:

- If the value of *start* is positive, the search proceeds to the right.
- If the value of *start* is negative, the search proceeds to the left.
- If the value of *start* is less than the negative length of the string, the search begins at the end of the string.

NOTXDIGIT returns a value of zero when one of the following is true:

- The character that you are searching for is not found.
- The value of *start* is greater than the length of the string.
- The value of *start* = 0.

Comparisons

The NOTXDIGIT function searches a character string for a character that is not a hexadecimal character. The ANYXDIGIT function searches a character string for a character that is a hexadecimal character.

Example

The following program uses the NOTXDIGIT function to search a string for a character that is not a hexadecimal character.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(18) string c;
   dcl double j i;
   method run();
      string='Next = _n_ + 12E3;';
      j=0;
      do until(j=0);
         j=notxdigit(string, j+1);
         if j=0 then put 'The end';
         else do;
            c=substr(string, j, 1);
            put j= c=;
         end;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
j=1 c=N
j=3 c=x
j=4 c=t
j=5 c=
j=6 c==
j=7 c=
j=8 c=_
j=9 c=n
j=10 c=_
j=11 c=
j=12 c=+
j=13 c=
j=18 c=;
The end
```

See Also

Functions:

- “ANYXDIGIT Function” on page 308

NPV Function

Returns the net present value with the rate expressed as a percentage.

Category: Financial

Returned data type: DOUBLE

Syntax

NPV(*r*, *freq*, *c0*, *c1*, ..., *cn*)

Required Arguments

r

is numeric, the interest rate over a specified base period of time expressed as a percentage.

Data type DOUBLE

freq

is numeric, the number of payments during the base period of time specified with the rate *r*.

Range *freq* > 0

Data type DOUBLE

Note The case *freq* = 0 is a flag to allow continuous discounting.

c0, c1, ..., cn

are numeric cash flows that represent cash outlays (payments) or cash inflows (income) occurring at times 0, 1, ...n. These cash flows are assumed to be equally spaced, beginning-of-period values. Negative values represent payments, positive values represent income, and values of 0 represent no cash flow at a given time. The *c0* argument and the *c1* argument are required.

Data type DOUBLE

Comparisons

The NPV function is identical to NETPV, except that the *r* argument is provided as a percentage.

See Also

Functions:

- “NETPV Function” on page 880

NULL Function

Returns a 1 if the argument is null and a 0 if the argument is not null.

Category: Special

Returned data type: INTEGER

Syntax

NULL(*expression*)

Required Argument

expression
specifies any valid expression.

Data type: All data types

Note: If you are using SAS Federation Server LIBNAME engine, ANSI null values are translated to SAS missing values in FedSQL CALL invocations when the DS2_SASMISSING environment variable is set to TRUE.

See: “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The NULL function returns a `1` only for a null value. It returns a `0` for any non-null value, including a SAS missing value.

The NULL function returns a `1` if a package instance does not exist, that is the package variable is a null package reference. The NULL function returns a `0` if the package variable references a package instance.

Note: Missing values and null values are treated differently in SAS mode versus ANSI mode. Missing and null values might be converted dependent on mode.

Example

The following program illustrates how NULL can differ in SAS mode and in ANSI mode.

In SAS mode, the following lines are written to the SAS log.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(1) a[3];
   dcl double  b[3];
   dcl int c[3];
   dcl int i;
   method run();
      a := ('a', '', NULL);
      b := (1, ., NULL);
      c := (1, NULL, NULL);
      do i = 1 to 3;
         if (null(a[i])) then put a[i]= 'null';
            else put a[i]= 'not null';
         if (null(b[i])) then put b[i]= 'null';
            else put b[i]= 'not null';
         if (null(c[i])) then put c[i]= 'null';
            else put c[i]= 'not null';
      end;
   end;
enddata;
run;
quit;
```

```
a[1]=a not null
b[1]=1 not null
c[1]=1 not null
a[2]=  not null
b[2]=. not null
c[2]= null
a[3]=  not null
b[3]=. not null
c[3]= null
```

In ANSI mode, the following lines are written to the SAS log.

```
a[1]=a not null
b[1]=1 not null
c[1]=1 not null
a[2]=  not null
b[2]= null
c[2]= null
a[3]= null
b[3]= null
c[3]= null
```

Note that in ANSI mode, **b[2]** is null because the SAS missing value (.) is converted to null before being assigned to **b[2]** in `b := (1, ., NULL);`. In SAS mode, **a[3]**

and b[3] are not null because the null value is converted to a SAS missing value (blank-filled string for **a[3]** and missing . for **b[3]**) before being assigned to **a[3]** and **b[3]** in `if (null(a[i])) then put a[i]= 'null';` and `else put a[i]= 'not null';`

- "NMISS Function" on page 882

NWKDOM Function

Returns the date for the *n*th occurrence of a weekday for the specified month and year.

Category: Date and Time

Returned data type: DOUBLE

Syntax

NWKDOM(*n*, *weekday*, *month*, *year*)

Required Arguments

n

specifies the numeric week of the month that contains the specified day.

Range 1–5

Data type DOUBLE

Tip *N*=5 indicates that the specified day occurs in the last week of that month. Sometimes *n*=4 and *n*=5 produce the same results.

weekday

specifies the number that corresponds to the day of the week.

Range 1–7

Data type DOUBLE

Tip Sunday is considered the first day of the week and has a *weekday* value of 1.

month
specifies the number that corresponds to the month of the year.

Range 1–12

Data type DOUBLE

year
specifies a four-digit calendar year.

Data type DOUBLE

Details

The NWKDOM function returns a SAS date value for the *n*th weekday of the month and year that you specify. Use any valid SAS date format, such as the DATE9. format, to display a calendar date. You can specify *n*=5 for the last occurrence of a particular weekday in the month.

Sometimes *n*=5 and *n*=4 produce the same result. These results occur when there are only four occurrences of the requested weekday in the month. For example, if the month of January begins on a Sunday, there are five occurrences of Sunday, Monday, and Tuesday, but only four occurrences of Wednesday, Thursday, Friday, and Saturday. In this case, specifying *n*=5 or *n*=4 for Wednesday, Thursday, Friday, or Saturday produces the same result.

If the year is not a leap year, February has 28 days and there are four occurrences of each day of the week. In this case, *n*=5 and *n*=4 produce the same results for every day.

Comparisons

In the NWKDOM function, the value for *weekday* corresponds to the numeric day of the week beginning on Sunday. This value is the same value that is used in the WEEKDAY function, where Sunday =1, and so on. The value for *month* corresponds to the numeric month of the year beginning in January. This value is the same value that is used in the MONTH function, where January =1, and so on.

You can use the NWKDOM function to calculate events that are not defined by the HOLIDAY function. For example, if a university always schedules graduation on the first Saturday in June, then you can use the following statement to calculate the date: `UnivGrad = nwkdom(1, 7, 6, year);`

Examples

Example 1: Returning Date Values

The following program uses the NWKDOM function and returns the date for specific occurrences of a weekday for a specified month and year.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a b c d e f;
   method run();
      /* Return the date of the third Monday in May 2012. */
      a=nwkdom(3, 2, 5, 2012);
      /* Return the date of the fourth Wednesday in November 2012. */
      b=nwkdom(4, 4, 11, 2012);
      /* Return the date of the fourth Saturday in November 2012. */
      c=nwkdom(4, 7, 11, 2012);
      /* Return the date of the first Sunday in January 2013. */
      d=nwkdom(1, 1, 1, 2013);
      /* Return the date of the second Tuesday in September 2012. */
      e=nwkdom(2, 3, 9, 2012);
      /* Return the date of the fifth Thursday in December 2012. */
      f=nwkdom(5, 5, 12, 2012);
      put a= weekdatx.;
      put b= weekdatx.;
      put c= weekdatx.;
      put d= weekdatx.;
      put e= weekdatx.;
      put f= weekdatx.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
a=          Monday, 21 May 2012
b=  Wednesday, 28 November 2012
c=   Saturday, 24 November 2012
d=       Sunday, 6 January 2013
e=   Tuesday, 11 September 2012
f=   Thursday, 27 December 2012
```

Example 2: Returning the Date of the Last Monday in May

The following program returns the date that corresponds to the last Monday in the month of May in the year 2012.

```
data _null_;
   dcl double x;
   method init();
      /* The last Monday in May. */
      x=nwkdom(5,2,5,2012);
```

```
        put x date9.;
    end;
enddata;
run;
```

SAS writes the following output to the log:

```
28MAY2012
```

ORDINAL Function

Orders a list of values, and returns a value that is based on a position in the list.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

ORDINAL(*position*, *expression-1, expression-2* [, ...*expression-n*])

Required Arguments

position
specifies a whole number that is less than or equal to the number of elements in the list of arguments.

Requirement *position* must be a positive number.

Data type DOUBLE

expression
specifies any valid expression that evaluates to a numeric value.

Requirement At least two arguments are required.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ORDINAL function sorts the list and returns the argument in the list that is specified by *position*. Missing values are sorted low and are placed before any numeric values.

Comparisons

The ORDINAL function counts both null, missing, non-null, and nonmissing values, whereas the SMALLEST function counts only non-null and nonmissing values.

Example

The following program illustrates the ORDINAL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=ordinal(4,1,2,3,-4,5,6,7);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
3
```

PCTL Function

Returns the percentile that corresponds to the percentage.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

PCTL[*n*](*percentage*, *expression*[, ...*expression*])

Required Argument

percentage
specifies the percentile to be computed.

Data type DOUBLE

Tips *percentage* is numeric where, 0≤*percentage*≤100.

percentage is numeric where, 0 ≤ *percentage* ≤ 100.

Optional Arguments

n
is a digit from 1 to 5 that specifies the definition of the percentile to be computed.

Default definition 5

Data type DOUBLE

See QNTLDEF= (alias PCTLDEF=) descriptions in the table “Methods for Computing Quantile Statistics” in the *Base SAS Procedures Guide*.

expression
specifies any valid expression that evaluates to a numeric value, whose value is computed in the percentile calculation.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The PCTL function returns the percentile of the non-null or nonmissing values corresponding to the percentage. If *percentage* is null or missing, less than zero, or greater than 100, the PCTL function generates an error message.

Example

The following program illustrates the PCTL function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double lower_quartile percentile_def2 lower_tertile
percentile_def3;
   dcl double median upper_tertile upper_quartile;
   method run();
      lower_quartile=pctl(25, 2, 4, 1, 3);
      put lower_quartile=;
      percentile_def2=pctl2(25, 2, 4, 1, 3);
      put percentile_def2=;
      lower_tertile=pctl(100/3, 2, 4, 1, 3);
      put lower_tertile=;
      percentile_def3=pctl3(100/3, 2, 4, 1, 3);
      put percentile_def3=;
      median=pctl(50, 2, 4, 1, 3);
      put median=;
      upper_tertile=pctl(200/3, 2, 4, 1, 3);
      put upper_tertile=;
      upper_quartile=pctl(75, 2, 4, 1, 3);
      put upper_quartile=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
lower_quartile=1.5
percentile_def2=1
lower_tertile=2
percentile_def3=2
median=2.5
upper_tertile=3
upper_quartile=3.5
```

PDF Function

Returns a value from a probability density (mass) distribution.

Category: Probability

Alias: PMF

Data type: DOUBLE

Syntax

PDF(*'distribution'*, *quantile* [, *parameter-1, ..., parameter-k*])

Required Arguments

distribution

is a character constant, variable, or expression that identifies the distribution. Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL' | 'GAUSS'
Normal mixture	'NORMALMIX'

Distribution	Argument
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD' | 'IGAUSS'
Weibull	'WEIBULL'

Note Except for T, F, and NORMALMIX, you can identify any distribution by its first four characters.

quantile
is a numeric constant, variable, or expression that specifies the value of the random variable.

Data type DOUBLE

parameter-1, ..., parameter-k
are optional numeric constants, variables, or expressions that specify the values of *shape*, *location*, or *scale* parameters that are appropriate for the specific distribution.

Data type DOUBLE

PDF BERNOULLI Distribution Function

Returns a value from the Bernoulli probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (’BERNOULLI’, *x*, *p*)

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

p

is a numeric constant, variable, or expression that specifies the probability of success.

Range $0 \leq p \leq 1$

Data type DOUBLE

Details

The PDF function for the Bernoulli distribution returns the probability density function with the probability of success equal to *p*. The PDF function is evaluated at the value *x*.

$$PDF('BERN', x, p) = \begin{cases} 0 & x < 0 \\ 1 - p & x = 0 \\ 0 & 0 < x < 1 \\ p & x = 1 \\ 0 & x > 1 \end{cases}$$

Note: There are no *location* or *scale* parameters for this distribution.

Example

The following program illustrates the PDF Bernoulli distribution function:

Note: In this example code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('BERN',0,.25);
      put 'Bern dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Bern dist:      0.75
```

PDF BETA Distribution Function

Returns a value from the beta probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('BETA', *x*, *a*, *b* [, *l*, *r*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

b

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $b > 0$

Data type DOUBLE

Optional Arguments

l

is a numeric constant, variable, or expression that specifies the left location parameter.

Default 0

Data type DOUBLE

r

is a numeric constant, variable, or expression that specifies the right location parameter.

Default	1
Range	$r > l$
Data type	DOUBLE

Details

The PDF function for the beta distribution returns the probability density function with the shape parameters *a* and *b*. The PDF function is evaluated at the value *x*.

$$PDF('BETA', x, a, b, l, r) = \begin{cases} 0 & x < l \\ \frac{1}{\beta(a,b)} \frac{(x-l)^{a-1}(r-x)^{b-1}}{(r-l)^{a+b-1}} & l \le x \le r \\ 0 & x > r \end{cases}$$

Note: The quantity $\frac{x-l}{r-l}$ is forced to be $\varepsilon \le \frac{x-l}{r-l} \le 1 - 2\varepsilon$.

Example

The following program illustrates the PDF Beta distribution function:

Note: In this example code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('BETA', 0.2, 3, 4);
      put 'Beta dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Beta dist:      1.2288
```

PDF BINOMIAL Distribution Function

Returns a value from the binomial probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF ('BINOMIAL', *m*, *p*, *n*)

Required Arguments

m

is a random variable that counts the number of successes. This argument must be a whole number.

Range	*m*=0, 1, ...
Data type	DOUBLE

p

is a numeric constant, variable, or expression that specifies the probability of success.

Range	$0 \le p \le 1$
Data type	DOUBLE

n

is a parameter that counts the number of independent Bernoulli trials. This argument must be a whole number.

Range	*n*=0, 1, ...
Data type	DOUBLE

Details

The PDF function for the binomial distribution returns the probability density function with the parameters *p* and *n*. The PDF function is evaluated at the value *m*.

$$PDF('BINOM', m, p, n) = \begin{cases} 0 & m < 0 \\ \binom{n}{m} p^m (1-p)^{n-m} & 0 \le m \le n \\ 0 & m > n \end{cases}$$

Note: There are no *location* or *scale* parameters for the binomial distribution.

Example

The following program illustrates the PDF Binomial distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('BINOM',4,.5,10);
      put 'Binom dist:     ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Binom dist:     0.205078125
```

PDF CAUCHY Distribution Function

Returns a value from the Cauchy probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('CAUCHY', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the Cauchy distribution returns the probability density function with the location parameter θ and the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('CAUCHY', x, \theta, \lambda) = \frac{1}{\pi}\left(\frac{\lambda}{\lambda^2 + (x-\theta)^2}\right)$$

Example

The following program illustrates the PDF Cauchy distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('CAUCHY',2);
      put 'Cauchy dist:    ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Cauchy dist:    0.06366197723675
```

PDF Chi-Square Distribution Function

Returns a value from the chi-square probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('CHISQUARE', *x*, *df* [, *nc*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

df

is a numeric constant, variable, or expression that specifies the degrees of freedom.

Range *df* > 0

Data type DOUBLE

Optional Argument

nc

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Range *nc* ≥ 0

Data type DOUBLE

Details

The PDF function for the chi-square distribution returns the probability density function of a chi-square distribution, with *df* degrees of freedom and the noncentrality parameter *nc*. The PDF function is evaluated at the value *x*. This function accepts noninteger degrees of freedom. If *nc* is omitted or equal to zero, the value returned is from the central chi-square distribution.

$$PDF('CHISQ', x, \nu, \lambda) = \begin{cases} 0 & x < 0 \\ \sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\left(\frac{\lambda}{2}\right)^j}{j!} p_c(x, \nu + 2j) & x \geq 0 \end{cases}$$

In this equation, $p_c(.,.)$ denotes the density from the central chi-square distribution:

$$p_c(x, a) = \frac{1}{2} p_g\left(\frac{x}{2}, \frac{a}{2}\right)$$

In this equation, $p_g(y,b)$ is the density from the gamma distribution:

$$p_g(y,b) = \frac{1}{\Gamma(b)} e^{-y} y^{b-1}$$

Example

The following program illustrates the PDF Chi-Square distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('CHISQ',11.264,11);
      put 'Chisq dist:     ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Chisq dist:     0.08168618682435
```

PDF Conway-Maxwell-Poisson Distribution Function

Returns a value from the Conway-Maxwell-Poisson probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF('CONMAXPOI',*y*,*λ*,*v*)

Required Arguments

y

is a numeric constant, variable, or expression that specifies a nonnegative, whole number representing a count.

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a location parameter, similar to the Poisson mean parameter.

Data type DOUBLE

v

is a numeric constant, variable, or expression that specifies a dispersion parameter.

Data type DOUBLE

Details

The Conway-Maxwell-Poisson (CMP) distribution is a generalization of the Poisson distribution that enables you to model underdispersed and overdispersed data. The CMP distribution is defined according to this equation:

$$P\left(Y = y\,;\lambda,\nu\right) = \frac{1}{Z(\lambda,\nu)}\frac{\lambda^{y}}{(y!)^{\nu}} \qquad y = 0, 1, 2, \ldots$$

The normalization factor is expressed by this equation:

$$Z\left(\lambda,\nu\right) = \sum_{n=0}^{\infty}\frac{\lambda^{n}}{(n!)^{\nu}}$$

λ and v are nonnegative and not simultaneously zero.

The additional parameter, v, allows for flexibility in modeling the tail behavior of the distribution. If v=1, the ratio is equal to the rate of decay of the Poisson distribution. If v<1, the rate of decay decreases, which enables you to model

processes that have longer tails than the Poisson distribution (overdispersed data). If v>1, the rate of decay increases in a nonlinear manner, thus shortening the tail of the distribution (underdispersed data).

There are several special cases of the Conway-Maxwell-Poisson distribution. If λ<1 and v→∞, the Conway-Maxwell-Poisson distribution results in the Bernoulli distribution. In this case, the data can take only the values 0 and 1, which represent an extreme underdispersion. If v=1, the Poisson distribution is recovered with its equidispersion property. When v=0 and λ<1, the normalization factor is convergent and forms this geometric series:

$$Z\left(\lambda, 0\right) = \frac{1}{1-\lambda}$$

The probability density function is represented by this equation:

$$P\left(Y = y\,;\lambda, \nu = 0\right) = \left(1-\lambda\right)\lambda^{y}$$

The geometric distribution represents a case of severe overdispersion.

Mean, Variance, and Dispersion for the Conway-Maxwell-Poisson Model

The mean and variance of the Conway-Maxwell-Poisson distribution are defined by these equations:

$$E\left[Y\right] = \frac{\partial\, 1n\ Z}{\partial\, 1n\, \lambda}$$

$$V\left[Y\right] = \frac{\partial^2\, 1n\, Z}{\partial^2\, 1n\, \lambda}$$

The Conway-Maxwell-Poisson distribution does not have closed-form expressions for its moments in terms of parameters λ and v. However, the moments can be approximated. (For more information about the Conway-Maxwell-Poisson distribution and discrete data, see the References section that is located at the end of this function.) Use asymptotic expressions for Z to derive E(Y) and V(Y) as these equations show:

$$E\left[Y\right] \approx \lambda^{1/\nu} + \frac{1}{2\nu} - \frac{1}{2}$$

$$V\left[Y\right] \approx \frac{1}{\nu}\lambda^{1/\nu}$$

In the Conway-Maxwell-Poisson model, the summation of infinite series is evaluated using a logarithmic expansion. (For more information about the Conway-Maxwell-Poisson distribution and discrete data, see the References section that is located at the end of this function.) The mean and variance are calculated as follows for the Conway-Maxwell-Poisson model:

$$E\left(Y\right) = \frac{1}{Z(\lambda,\nu)}\sum_{j=0}^{\infty}\frac{j\lambda^{j}}{(j!)^{\nu}}$$

$$V\left(Y\right) = \frac{1}{Z(\lambda,\nu)}\sum_{j=0}^{\infty}\frac{j^{2}\lambda^{j}}{(j!)^{\nu}} - E(Y)^{2}$$

The dispersion is defined as follows:

$$D\left(Y\right) = \frac{V(Y)}{E(Y)}$$

Example

The following program illustrates the PDF Conway-Maxwell-Poisson distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('CONMAXPOI', .2, 2.3, .4);
      put 'ConMaxPoi dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
ConMaxPoi dist:      0.00977326351239
```

PDF EXPONENTIAL Distribution Function

Returns a value from the exponential probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('EXPONENTIAL', *x* [, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Argument

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the exponential distribution returns the probability density function of an exponential distribution, with the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('EXPO', x, \lambda) = \begin{cases} 0 & x < 0 \\ \frac{1}{\lambda} exp\left(-\frac{x}{\lambda}\right) & x \geq 0 \end{cases}$$

Example

The following program illustrates the PDF Exponential distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('EXPO',1);
```

```
        put 'Expo dist:      ' y;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Expo dist:      0.36787944117144
```

PDF F Distribution Function

Returns a value from the F probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (‘F’, *x*, *ndf*, *ddf* [, *nc*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

ndf

is a numeric constant, variable, or expression that specifies the numerator degrees of freedom.

Range *ndf*> 0

Data type DOUBLE

ddf

is a numeric constant, variable, or expression that specifies the denominator degrees of freedom.

Range *ddf* > 0

Data type DOUBLE

Optional Argument

nc

is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Range *nc* ≥ 0

Data type DOUBLE

Details

The PDF function for the *F* distribution returns the probability density function of an *F* distribution, with *ndf* numerator degrees of freedom, *ddf* denominator degrees of freedom, and the noncentrality parameter *nc*. The PDF function is evaluated at the value *x*. This PDF function accepts noninteger degrees of freedom for *ndf* and *ddf*. If *nc* is omitted or equal to zero, the value returned is from a central *F* distribution. In the following equation, let $\nu_1 = ndf$, let $\nu_2 = ddf$, and let $\lambda = nc$. This equation describes the PDF function for the *F* distribution:

$$PDF('F', x, \nu_1, \nu_2, \lambda) = \begin{cases} 0 & x < 0 \\ \sum_{j=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\left(\frac{\lambda}{2}\right)^j}{j!} p_f(f, \nu_1 + 2j, \nu_2) & x \geq 0 \end{cases}$$

In the equation, $p_f(f,u_1,u_2)$ is the density from the central *F* distribution:

$$p_f(f, u_1, u_2) = p_B\left(\frac{u_1 f}{uf + u_2}, \frac{u_1}{2}, \frac{u_2}{2}\right) \frac{u_1 u_2}{(u_2 + u_1 f)^2}$$

In the equation, $p_B(x,a,b)$ is the density from the standard beta distribution.

Note: There are no *location* or *scale* parameters for the *F* distribution.

Example

The following program illustrates the PDF F distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
     y=pdf('F',3.32,2,3);
     put 'F dist:          ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
F dist:         0.05402696258579
```

PDF GAMMA Distribution Function

Returns a value from the gamma probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF ('GAMMA', *x*, *a* [, *λ*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

Optional Argument

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range $\lambda > 0$

Data type DOUBLE

Details

The PDF function for the gamma distribution returns the probability density function of a gamma distribution, with the shape parameter *a* and the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('GAMMA', x, a, \lambda) = \begin{cases} 0 & x < 0 \\ \frac{1}{\lambda^a \Gamma(a)} x^{a-1} exp\left(-\frac{x}{\lambda}\right) & x \geq 0 \end{cases}$$

Example

The following program illustrates the PDF Gamma distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
```

```
      method init();
         y=pdf('GAMMA',1,3);
         put 'Gamma dist:     ' y;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log:

```
Gamma dist:     0.18393972058572
```

PDF Generalized Poisson Distribution Function

Returns a value from the generalized Poisson probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (‘GENPOISSON’, *x*, *θ*, *η*)

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Data type DOUBLE

θ

is a numeric constant, variable, or expression that specifies a shape parameter.

Range <10^5 and >0

Data type DOUBLE

η

is a numeric constant, variable, or expression that specifies a shape parameter.

Range ≥0 and <0.95

Data type DOUBLE

Tip When η =0, the distribution is the Poisson distribution with a mean and variance of θ. When η>0, the mean is $\theta \div (1-\eta)$ and the variance is $\theta \div (1-\eta)^3$.

Details

Here is the probability mass function for the generalized Poisson distribution:

$$f(x;\theta,\eta) = \theta(\theta+\eta x)^{x-1} e^{-\theta-\eta x}/x!, \quad x = 0,1,2,..., \qquad \theta > 0,\ 0 \le \eta < 1$$

Example

The following program illustrates the PDF Generalized Poisson distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('GENPOISSON', 9, 1, .7);
      put 'GENPOISSON dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
GENPOISSON dist:      0.01501309145504
```

PDF GEOMETRIC Distribution Function

Returns a value from the geometric probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (‘GEOMETRIC’, *m*, *p*)

Required Arguments

m

is a numeric constant, variable, or expression that specifies the number of failures before the first success.

Range	$m \geq 0$
Data type	DOUBLE

p

is a numeric constant, variable, or expression that specifies a probability of success.

Range	$0 \leq p \leq 1$
Data type	DOUBLE

Details

The PDF function for the geometric distribution returns the probability density function of a geometric distribution, with the parameter *p*. The PDF function is evaluated at the value *m*.

$$PDF('GEOM', m, p) = \begin{cases} 0 & m < 0 \\ p(1-p)^m & m \geq 0 \end{cases}$$

Note: There are no *location* or *scale* parameters for this distribution.

Example

The following program illustrates the PDF Geometric distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
     y=pdf('GEOMETRIC', 5, .3);
     put 'geometric dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
geometric dist:      0.050421
```

PDF Hypergeometric Distribution Function

Returns a value from a hypergeometric probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('HYPER', *x*, *N*, *R*, *n* [, *o*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Data type DOUBLE

N

is a numeric constant, variable, or expression that specifies a population size parameter. This argument must be a whole number.

Range *N*=1, 2, ...

Data type DOUBLE

R

is a numeric constant, variable, or expression that specifies the number of items in the category of interest. This argument must be a whole number.

Range *R*=0, 1, ..., *N*

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies a sample size parameter. This argument must be a whole number.

Range *n*=1, 2, ..., *N*

Data type DOUBLE

Optional Argument

o

is a numeric constant, variable, or expression that specifies an optional odds ratio parameter.

Range $o > 0$

Data type DOUBLE

Details

The PDF function for the hypergeometric distribution returns the probability density function of an extended hypergeometric distribution, with population size *N*, number of items *R*, sample size *n*, and odds ratio *o*. The PDF function is evaluated at the value *x*. If *o* is omitted or equal to 1, the value returned is from the usual hypergeometric distribution.

$$PDF\ ('HYPER', x, N, R, n, o) = \begin{cases} 0 & x < max(0, R+n-N) \\ \dfrac{\binom{R}{x}\binom{N-R}{n-x}o^x}{\sum_{j=max(0,R+n-N)}^{min(R,n)}\binom{R}{j}\binom{N-R}{n-j}o^j} & max(0, R+n-N) \le x \le min(R,n) \\ 0 & x > min(R,n) \end{cases}$$

Example

The following program illustrates the PDF Hypergeometric distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('HYPER', 2, 200, 50, 10);
      put 'Hyper dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Hyper dist:      0.28685059643368
```

PDF LAPLACE Distribution Function

Returns a value from the Laplace probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF (‘LAPLACE’, *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ
is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the Laplace distribution returns the probability density function of the Laplace distribution, with the location parameter θ and the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('LAPLACE', x, \theta, \lambda) = \frac{1}{2\lambda} exp\left(- \frac{|x - \theta|}{\lambda} \right)$$

Example

The following program illustrates the PDF Laplace distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('LAPLACE', 1);
      put 'Laplace dist:   ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Laplace dist:   0.18393972058572
```

PDF LOGISTIC Distribution Function

Returns a value from the logistic probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('LOGISTIC', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the logistic distribution returns the probability density function of a logistic distribution, with the location parameter θ and the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('LOGISTIC', x, \theta, \lambda) = \frac{exp\left(-\frac{x-\theta}{\lambda}\right)}{\lambda\left(1+exp\left(-\frac{x-\theta}{\lambda}\right)\right)^2}$$

Example

The following program illustrates the PDF Logistic distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('LOGISTIC', 1);
      put 'Logistic dist:   ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Logistic dist:   0.19661193324148
```

PDF LOGNORMAL Distribution Function

Returns a value from the lognormal probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('LOGNORMAL', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a log scale parameter. exp(θ) is a scale parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a shape parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the lognormal distribution returns the probability density function of a lognormal distribution, with the log scale parameter θ and the shape parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('LOGN', x, \theta, \lambda) = \begin{cases} 0 & x \leq 0 \\ \frac{1}{x\lambda\sqrt{2\,\pi}}\ exp\left(-\frac{(log(x)-\theta)^2}{2\lambda^2}\right) & x > 0 \end{cases}$$

Example

The following program illustrates the PDF Lognormal distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('LOGNORMAL', 1);
      put 'LogNormal dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
LogNormal dist:      0.39894228040143
```

PDF NEGBINOMIAL Distribution Function

Returns the value from the negative binomial probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF ('NEGBINOMIAL', *m*, *p*, *n*)

Required Arguments

m

is a numeric constant, variable, or expression that specifies a random variable that counts the number of failures. This argument must be a positive, whole number.

Range *m*=0, 1, ...

Data type DOUBLE

p

is a numeric constant, variable, or expression that specifies a probability of success.

Range $0 \le p \le 1$

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies a value that counts the number of successes.

Range *n*>0

Data type DOUBLE

Details

The PDF function for the negative binomial distribution returns the probability density function of a negative binomial distribution, with probability of success *p* and number of successes *n*. The PDF function is evaluated at the value *m*.

$$PDF('NEGB', m, p, n) = \begin{cases} 0 & m < 0 \\ \binom{n+m-1}{n-1} p^n (1-p)^m & m \ge 0 \end{cases}$$

Note: There are no *location* or *scale* parameters for the negative binomial distribution.

Example

The following program illustrates the PDF Negative Binomial distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('NEGB',1,.5,2);
      put 'NegB dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
NegB dist:      0.25
```

PDF NORMAL Distribution Function

Returns a value from the normal probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF ('NORMAL', *x* [, *θ*, *λ*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

θ

is a numeric constant, variable, or expression that specifies a location parameter.

Default 0

Data type DOUBLE

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ > 0

Data type DOUBLE

Details

The PDF function for the normal distribution returns the probability density function of a normal distribution, with the location parameter θ and the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('NORMAL', x, \theta, \lambda) = \frac{1}{\lambda\sqrt{2\,\pi}}\ exp\left(-\frac{(x-\theta)^2}{2\lambda^2}\right)$$

Example

The following program illustrates the PDF Normal distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
```

```
   method init();
      y=pdf('NORMAL',1.96);
      put 'Normal dist:    ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Normal dist:    0.05844094433345
```

PDF NORMALMIX Distribution Function

Returns a value from the normal mixture probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (‘NORMALMIX’, *x*, *n*, p_1, p_2, ... p_n, m_1, m_2, ... m_n, s_1, s_2, ... s_n)

Required Arguments

x
is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

n

is a numeric constant, variable, or expression that specifies the number of mixtures. This argument must be a whole number.

Range *n*=1, 2, ...

Data type DOUBLE

p_i

is a list of numeric constants, variables, or expressions that specifies the *n* proportions, $p_1, p_2, \ldots, p_n$, where $\sum_{i=1}^{i=n} p_i = 1$.

Range *p*=0, 1, ...

Data type DOUBLE

m_i

is a list of numeric constants, variables, or expressions that specifies the *n* means $m_1, m_2, \ldots, m_n$.

s_i

is a list of numeric constants, variables, or expressions that specifies the *n* standard deviations $s_1, s_2, \ldots, s_n$.

Range $s > 0$

Data type DOUBLE

Details

The PDF function for the Normal Mixture distribution returns the probability that an observation from a mixture of normal distribution is less than or equal to *x*.

$$PDF('NORMALMIX', x, n, p, m, s) = \sum_{i=1}^{i=n} p_i \, PDF('NORMAL', x, m_i, s_i)$$

Weights for the Normal Mixture distribution must be nonnegative. If the sum of the weights does not equal 1, then the weights are treated as relative weights and adjusted so that the sum equals 1.

Note: There are no *location* or *scale* parameters for the Normal Mixture distribution.

Example

The following program illustrates the PDF Normal Mixture distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('NORMALMIX',2.3, 3, .33, .33, .34,
       .5, 1.5, 2.5, .79, 1.6, 4.3);
      put 'Normal mix dist:' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Normal mix dist: 0.11655396435559
```

PDF PARETO Distribution Function

Returns a value from the Pareto probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF ('PARETO', *x*, *a* [, *k*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a numeric random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

Optional Argument

k

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range $k > 0$

Data type DOUBLE

Details

The PDF function for the Pareto distribution returns the probability density function of a Pareto distribution, with the shape parameter *a* and the scale parameter *k*. The PDF function is evaluated at the value *x*.

$$PDF('PARETO', x, a, k) = \begin{cases} 0 & x < k \\ \frac{a}{k}\left(\frac{k}{x}\right)^{a+1} & x \geq k \end{cases}$$

Example

The following program illustrates the PDF Pareto distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
```

```
    dcl double y;
    method init();
      y=pdf('PARETO', 1, 1);
      put 'Pareto dist:      ' y;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Pareto dist:      1
```

PDF POISSON Distribution Function

Returns a value from the Poisson probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (’POISSON’, *n*, *m*)

Required Arguments

n

is a numeric constant, variable, or expression that specifies a random variable. This argument must be a whole number.

Range *n*=0, 1, ...

Data type DOUBLE

m

is a numeric constant, variable, or expression that specifies a mean parameter.

Range $m > 0$

Data type DOUBLE

Details

The PDF function for the Poisson distribution returns the probability density function of a Poisson distribution, with mean *m*. The PDF function is evaluated at the value *n*.

$$PDF('POISSON', n, m) = \begin{cases} 0 & n < 0 \\ e^{-m}\frac{m^n}{n!} & n \geq 0 \end{cases}$$

Note: There are no *location* or *scale* parameters for the Poisson distribution.

Example

The following program illustrates the PDF Poisson distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('POISSON', 2, 1);
      put 'Poisson dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Poisson dist:      0.18393972058572
```

PDF T Distribution Function

Returns a value from the T probability density (mass) distribution.

Category: Probability

Alias: PMF

Returned data type: DOUBLE

Syntax

PDF (‘T’, *t*, *df* [, *nc*])

Required Arguments

t

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

df

is a numeric constant, variable, or expression that specifies the degrees of freedom.

Range *df* > 0

Data type DOUBLE

Optional Argument

nc
is a numeric constant, variable, or expression that specifies an optional noncentrality parameter.

Data type DOUBLE

Details

The PDF function for the *T* distribution returns the probability density function of a *T* distribution, with degrees of freedom *df* and the noncentrality parameter *nc*. The PDF function is evaluated at the value *x*. This PDF function accepts noninteger degrees of freedom. If *nc* is omitted or equal to zero, the value returned is from the central *T* distribution. In this equation, let $\nu = df$ and let $\delta = nc$.

$$PDF('T', t, \nu, \delta) = \frac{1}{2^{\frac{\nu}{2}-1}\Gamma\left(\frac{\nu}{2}\right)} \int_0^{\infty} x^{\nu-1} e^{-\frac{1}{2}x^2} \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{tx}{\sqrt{\nu}}-\delta\right)^2} \frac{x}{\sqrt{\nu}} dx$$

Note: There are no *location* or *scale* parameters for the *T* distribution.

Example

The following program illustrates the PDF T distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('T',.9,5);
      put 'T dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
T dist:      0.24194434361358
```

See Also

PDF TWEEDIE Distribution Function

Returns a value from the Tweedie probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (’TWEEDIE’, *y*, *p* [, *μ*, *ϕ*])

Required Arguments

y

is a numeric constant, variable, or expression that specifies a random variable.

Range	$y \geq 0$
Data type	DOUBLE
Notes	This argument is required.
	When $y>1$, y is numeric. When $p=1$, y is a whole number.

p

is a numeric constant, variable, or expression that specifies the power parameter.

Range	$p \geq 1$

Data type DOUBLE

Note This argument is required.

Optional Arguments

μ

is a numeric constant, variable, or expression that specifies the mean parameter.

Default 1

Range μ >0

Data type DOUBLE

ϕ

is a numeric constant, variable, or expression that specifies the dispersion parameter.

Default 1

Range ϕ>0

Data type DOUBLE

Details

The PDF function for the Tweedie distribution returns an exponential dispersion model with variance and mean related by the equation *variance*= $\phi * \mu^p$.

$$\frac{1}{y}\sum_{j=1}^{\infty}\left(\frac{y^{-j\alpha}(p-1)^{j\alpha}}{\phi^{j(1-\alpha)}(2-p)^{j}j!\Gamma(-j\alpha)}\right)\exp\left(\frac{1}{\phi}\left(y\frac{\mu^{1-p}-1}{1-p}-\frac{\mu^{2-p}-1}{2-p}\right)\right)$$

The following relationship applies to the preceding equation:

$$\alpha=\frac{2-p}{1-p}$$

Note: The accuracy of computed Tweedie probabilities is highly dependent on the location in parameter space. Ten digits of accuracy are usually available except when p is near 2 or ϕ is near 0. In either of these cases, the accuracy might be as low as six digits.

Note: To avoid issues with numerical data, μ and Φ cannot be less than the constant SQRTMACEPS.

Example

The following program illustrates the PDF Tweedie distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('TWEEDIE', .8, 5);
      put 'Tweedie dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Tweedie dist:      0.74229082358846
```

PDF UNIFORM Distribution Function

Returns a value from the uniform probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF ('UNIFORM', *x* [, *l*, *r*])

Required Argument

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

Optional Arguments

l

is a numeric constant, variable, or expression that specifies the left location parameter.

Default 0

Data type DOUBLE

r

is a numeric constant, variable, or expression that specifies the right location parameter.

Default 1

Range $r > l$

Data type DOUBLE

Details

The PDF function for the uniform distribution returns the probability density function of a uniform distribution, with the left location parameter *l* and the right location parameter *r*. The PDF function is evaluated at the value *x*.

$$PDF('UNIFORM', x, l, r) = \begin{cases} 0 & x < l \\ \frac{1}{r-l} & l \le x \le r \\ 0 & x > r \end{cases}$$

Example

The following program illustrates the PDF Uniform distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('UNIFORM', 0.25);
      put 'Uniform dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Uniform dist:      1
```

PDF Wald (Inverse Gaussian) Distribution Function

Returns a value from the Wald (also known as the inverse Gaussian) probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF (‘WALD’, *x*, *λ* [, *μ*])

PDF (‘IGAUSS’, *x*, *λ* [, *μ*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

λ

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $\lambda > 0$

Optional Argument

μ

is a numeric constant, variable, or expression that specifies the mean parameter.

Default 1

Range $\mu > 0$

Details

The PDF function for the Wald distribution returns the probability density function of a Wald distribution, with the shape parameter λ, which is evaluated at the value *x*.

$$fx(x) = \left[\frac{\lambda}{2\pi x^3}\right]^{1/2} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x-\mu)^2\right\}, \qquad x > 0$$

Example

The following program illustrates the PDF Wald distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('WALD', 1, 2);
      put 'Wald dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Wald dist:      0.56418958354775
```

PDF WEIBULL Distribution Function

Returns a value from the Weibull probability density (mass) distribution.

Category:	Probability
Alias:	PMF
Returned data type:	DOUBLE

Syntax

PDF('WEIBULL', *x*, *a* [, *λ*])

Required Arguments

x

is a numeric constant, variable, or expression that specifies a random variable.

Data type DOUBLE

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

Data type DOUBLE

Optional Argument

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default	1
Range	λ > 0
Data type	DOUBLE

Details

The PDF function for the Weibull distribution returns the probability density function of a Weibull distribution, with the shape parameter *a* and the scale parameter λ. The PDF function is evaluated at the value *x*.

$$PDF('WEIBULL', x, a, \lambda) = \begin{cases} 0 & x < 0 \\ exp\left(-\left(\frac{x}{\lambda}\right)^a\right)\frac{a}{\lambda}\left(\frac{x}{\lambda}\right)^{a-1} & x \geq 0 \end{cases}$$

Example

The following program illustrates the PDF Weibull distribution function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method init();
      y=pdf('WEIBULL', 1, 2);
      put 'WEIBULL dist:      ' y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
WEIBULL dist:      0.73575888234288
```

PERM Function

Computes the number of permutations of *n* items that are taken *r* at a time.

Category: Combinatorial

Returned data type: DOUBLE

Syntax

PERM(*n*[, *r*])

Required Argument

n

specifies any valid expression that represents the total number of elements from which the sample is chosen.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

r

Specifies any valid expression that represents the number of chosen elements.

Restriction $r \leq n$

Data type DOUBLE

Note If *r* is omitted, the function returns the factorial of *n*.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The mathematical representation of the PERM function is given by the following equation:

$$PERM(n,r) = \frac{n!}{(n-r)!}$$

with $n \geq 0$, $r \geq 0$, and $n \geq r$.

If the expression cannot be computed, a missing value is returned. For moderately large values, it is sometimes not possible to compute the PERM function.

Example

The following program illustrates the PERM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
 proc ds2;
data _null_;
   dcl double x y z;
   method run();
      x=perm(5,1);
      y=perm(5);
      z=perm(5, 2);
      put x y z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
5 120 20
```

PMT Function

Returns the periodic payment for a constant payment loan or the periodic savings for a future balance.

Category: Financial

Returned data type: DOUBLE

Syntax

PMT(*rate*, *number-of-periods*, *principal-amount*[, *future-amount*][, *type*])

Required Arguments

rate
specifies the interest rate per payment period.

Data type DOUBLE

number-of-periods
specifies the number of payment periods.

Requirement *Number-of-periods* must be a positive whole number.

Data type DOUBLE

principal-amount
specifies the principal amount of the loan. Zero is assumed if a null or missing value is specified.

Data type DOUBLE

Optional Arguments

future-amount
specifies the future amount. *Future-amount* can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of periodic savings. Zero is assumed if *future-amount* is omitted or if a missing value is specified.

Data type DOUBLE

type
specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if *type* is omitted or if a null or missing value is specified.

Data type DOUBLE

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

- The monthly payment for a $10,000 loan with a nominal annual interest rate of 8% and 10 end-of-month payments can be computed in the following ways:

```
proc ds2;
data _null_;
   dcl double Payment1;
   method init();
      Payment1 = PMT(0.08/12., 10, 10000);
      /* same results with PMT(0.08/12., 10, 10000, 0, 0) ***/
      put Payment1=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1037.03208935915
```

- If the same loan has beginning-of-period payments, then payment can be computed as follows:

```
proc ds2;
data _null_;
   dcl double Payment2;
   method init();
      Payment2 = PMT(0.08/12., 10, 10000, 0, 1);
      put Payment2= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1030.16432717796
```

- The payment for a $5,000 loan earning a 12% nominal annual interest rate that is to be paid back in five monthly payments is computed as follows:

```
proc ds2;
data _null_;
   dcl double Payment3;
   method init();
      Payment3 = PMT(.01/12., 5, 5000);
      put Payment3= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1002.50138831008
```

- The payment for monthly periodic savings that accrue more than 18 years at a 6% nominal annual interest rate and that accumulate $50,000 at the end of the 18 years is computed as follows:

```
proc ds2;
data _null_;
   dcl double Payment4;
   method init();
      /* this generates a negative number */
      Payment4 = PMT(.06/12., 216, 0, 50000, 0);
      put Payment4= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
-129.081160867993
```

POISSON Function

Returns the probability from a Poisson distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

POISSON(*m*, *n*)

Required Arguments

m

specifies any valid expression that evaluates to a numeric mean parameter.

Range $m \geq 0$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

n

specifies any valid expression that evaluates to a random variable.

Range $n \geq 0$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The POISSON function returns the probability that an observation from a Poisson distribution, with mean *m*, is less than or equal to *n*. To compute the probability that an observation is equal to a given value, *n*, compute the difference of two probabilities from the Poisson distribution for *n* and *n*−1.

Example

The following program illustrates the POISSON function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=poisson(1,2);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.9196986029286
```

POWER Function

Returns the value of a numeric value expression raised to a specified power.

Category: Mathematical

Returned data type: DOUBLE

Syntax

POWER(*numeric-expression*, *whole-number-expression*)

Required Arguments

numeric-expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

whole-number-expression
specifies any valid expression that evaluates to a numeric value. This argument must be a whole number.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If *numeric-expression* is null, then the POWER function returns null. If the result is a number that does not fit into the range of the argument's data type, the POWER function fails.

Example

The following program illustrates the POWER function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=power(5*3, 2);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
225
```

PPMT Function

Returns the principal payment for a given period for a constant payment loan or the periodic savings for a future balance.

Category: Financial

Returned data type: DOUBLE

Syntax

PPMT(*rate*, *period*, *number-of-periods*, *principal-amount*[, *future-amount*][, *type*])

Required Arguments

rate
specifies the interest rate per payment period.

Data type DOUBLE

period
specifies the payment period for which the principal payment is computed.

Requirement *Period* must be a whole number that is less than or equal to the value of *number-of-periods*

Data type DOUBLE

number-of-periods
specifies the number of payment periods.

Requirement *Number-of-periods* must be a positive whole number.

Data type DOUBLE

principal-amount
specifies the principal amount of the loan. Zero is assumed if a null or missing value is specified.

Data type DOUBLE

Optional Arguments

future-amount
specifies the future amount. *Future-amount* can be the outstanding balance of a loan after the specified number of payment periods, or the future balance of

periodic savings. Zero is assumed if *future-amount* is omitted or if a null or missing value is specified.

Data type DOUBLE

type

specifies whether the payments occur at the beginning or end of a period. 0 represents the end-of-period payments, and 1 represents the beginning-of-period payments. 0 is assumed if *type* is omitted or if a null or missing value is specified.

Data type DOUBLE

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

- The principal payment amount of the first monthly periodic payment for a 2-year, $2,000 loan with a nominal annual interest rate of 10% is computed as follows:

```
proc ds2;
data test(overwrite=yes);
   dcl double PrincipalPayment;
   method run();
      PrincipalPayment = PPMT(0.1/12., 1, 24, 2000);
      put PrincipalPayment;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
75.6231860083663
```

- The principal payment for a 3-year, $20,000 loan with beginning-of-month payments is computed as follows:

```
proc ds2;
data test(overwrite=yes);
   dcl double PrincipalPayment2;
   method run();
      PrincipalPayment2 = PPMT(0.1/12, 1, 36, 20000, 0, 1);
      put PrincipalPayment2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log as the principal that was paid with the first payment:

```
640.010324505867
```

- The principal payment of an end-of-month payment loan with an outstanding balance of $5,000 at the end of three years is computed as follows:

```
proc ds2;
data test(overwrite=yes);
   dcl double PrincipalPayment3;
   method run();
      PrincipalPayment3 = PPMT(0.1/12, 1, 36, 20000, 5000, 0);
      put PrincipalPayment3;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log as the principal that was paid with the first payment:

```
359.007807907562
```

PROBBETA Function

Returns the probability from a beta distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBBETA(*x*, *a*, *b*)

Required Arguments

x

is a numeric random variable.

Range $0 \leq x \leq 1$

Data type DOUBLE

a

is a numeric shape parameter.

Range $a > 0$

Data type DOUBLE

b

is a numeric shape parameter.

Range	$b > 0$
Data type	DOUBLE

Details

The PROBBETA function returns the probability that an observation from a beta distribution, with shape parameters *a* and *b*, is less than or equal to *x*.

Example

The following program illustrates the PROBBETA function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x;
   method run();
      x=probbeta(.2,3,4);
      put x= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0.09888
```

PROBBNML Function

Returns the probability from a binomial distribution.

Category:	Probability
Returned data type:	DOUBLE

Syntax

PROBBNML(*p*, *n*, *m*)

Required Arguments

p

is a numeric probability of success parameter.

Range $0 \le p \le 1$

Data type DOUBLE

n

is the number of independent Bernoulli trials parameter. This argument must be a whole number.

Range $n > 0$

Data type DOUBLE

m

is the number of successes random variable. This argument must be a whole number.

Range $0 \le m \le n$

Data type DOUBLE

Details

The PROBBNML function returns the probability that an observation from a binomial distribution, with probability of success *p*, number of trials *n*, and number of successes *m*, is less than or equal to *m*. To compute the probability that an observation is equal to a given value *m*, compute the difference of two probabilities from the binomial distribution for *m* and *m*−1 successes.

Example

The following program illustrates the PROBBNML function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method run();
      x=probbnml(0.5,10,4);
      put x= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0.376953125
```

PROBBNRM Function

Returns a probability from a bivariate normal distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBBNRM(*x*, *y*, *r*)

Required Arguments

x

specifies a numeric constant, variable, or expression.

Data type DOUBLE

y

specifies a numeric constant, variable, or expression.

Data type DOUBLE

r

is a numeric correlation coefficient.

Range $-1 \le r \le 1$

Data type DOUBLE

Details

The PROBBNRM function returns the probability that an observation (X, Y) from a standardized bivariate normal distribution with mean 0, variance 1, and a correlation coefficient *r*, is less than or equal to (*x*, *y*). That is, it returns the probability that X≤*x* and Y≤*y*. The following equation describes the PROBBNRM function, where *u* and *v* represent the random variables *x* and *y*, respectively:

$$\mathrm{PROBBNRM}(x, y, r) = \frac{1}{2\pi\sqrt{1-r^2}} \int_{-\infty}^{x} \int_{-\infty}^{y} \exp\left[-\frac{u^2 - 2ruv + v^2}{2(1-r^2)} \right] dv\, du$$

Example

The following program illustrates the PROBBNRM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double p;
   method run();
      p=probbnrm(.4, -.3, .2);
      put p= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.27831833451901
```

PROBCHI Function

Returns the probability from a chi-square distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBCHI(*x*, *df*[, *nc*])

Required Arguments

x
is a numeric random variable.

Range $x \geq 0$

Data type DOUBLE

df
is a numeric degrees of freedom parameter.

Range $df > 0$

Data type DOUBLE

Optional Argument

nc
is an optional numeric noncentrality parameter.

Range $nc \geq 0$

Data type DOUBLE

Details

The PROBCHI function returns the probability that an observation from a chi-square distribution, with degrees of freedom *df* and noncentrality parameter *nc*, is less than or equal to *x*. This function accepts a noninteger degrees of freedom parameter *df*. If the optional parameter *nc* is not specified or has the value 0, the value returned is from the central chi-square distribution.

Example

The following program illustrates the PROBCHI function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=probchi(11.264,11);
      put x= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.5785813293173
```

PROBDF Function

Calculates significance probabilities for Dickey-Fuller tests for unit roots in time series.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBDF(*x*, *n*[, *d*[, *type*]])

Required Arguments

x

is the test statistic.

Data type DOUBLE

n

is the sample size. The minimum value of *n* that is allowed depends on the value that is specified for the third argument, *d*. For *d* in the set (1,2,4,6,12), *n* must be a whole number greater than or equal to `max(2d,5)`. For other values of *d* the minimum value of *n* is 24.

Data type DOUBLE

Optional Arguments

d

is a whole number that gives the degree of the unit root that is tested for. For tests of a simple unit root, `(1-B)`, specify *d*=1. For tests for a seasonal unit root, specify that *d* is equal to the seasonal cycle length for tests. The default value of *d* is 1. That is, a test for a simple unit root is assumed if *d* is not specified. The maximum value of *d* is 12.

Data type DOUBLE

type

is a character argument that specifies the type of test statistic that is used. The values of *type* are the following: RSM (regression single mean intercept), RTR (regression deterministic time trend), RZM (regression zero mean, no intercept), SSM (studentized single mean intercept), STR (studentized deterministic time trend), and SZM (studentized zero mean, no intercept). For additional information, see SAS DS2 Language Reference.

is a character argument that specifies the type of test statistic that is used. The values of *type* are the following:

RSM

specifies the regression test statistic for the single mean (intercept) case.

RTR

specifies the regression test statistic for the deterministic time trend case.

RZM
specifies the regression test statistic for the zero mean (no intercept) case.

SSM
specifies the studentized test statistic for the single mean (intercept) case.

STR
specifies the studentized test statistic for the deterministic time trend case.

SZM
specifies the studentized test statistic for the zero mean (no intercept) case.

Default SZM

Restriction The values STR and RTR are allowed only when *d*=1.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Theoretical Background

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey (1976) and Dickey and Fuller (1979) studied the limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root. Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots. This section introduces the nonseasonal tests, and lists references for the nonseasonal tests.

In the Dicky-Fuller regression, the null hypothesis states that there is an autoregressive unit root $H_0 : \alpha = 1$, and an alternative, $H_\alpha : |\alpha| < 1$, where α is the autoregressive coefficient of the following time series:

$$y_t = \alpha y_{t-1} + \varepsilon_t$$

This model is referred to as the zero mean (ZM) model. The standard Dickey-Fuller (DF) test assumes that errors are white noise. There are two other types of regression models that include a constant or a time trend:

$$y_t = \mu + \alpha y_{t-1} + \varepsilon_t$$

$$y_t = \mu + \beta t + \alpha y_{t-1} + \varepsilon_t$$

These two models are referred to as the constant mean model (SM) and the trend model (TR), respectively. The constant mean model includes a constant mean μ of the time series. However, the interpretation of μ depends on the stationarity in the following sense: the mean in the stationary case when α < 1 is the trend in the integrated case when α = 1. Therefore, the null hypothesis should be the joint hypothesis that α = 1 and μ = 0. However, for the unit root tests, the test statistics are concerned with the null hypothesis of α = 1. The joint null hypothesis is not commonly used. This issue is address in Bhargava, A. (1986) with a different nesting model.

Under the null of I(1) of the Dickey-Fuller test, the differenced process is not serially correlated. There is a great need for the generalization of this specification. The augmented Dickey-Fuller (ADF) test, originally proposed in Dickey and Fuller (1979), adjusts for the serial correlation in the time series by adding lagged first differences to the autoregressive model as follows. Consider the (p +1)th order autoregressive time series:

$$y_t = \alpha_1 y_{t-1} + \alpha_2 y_{t-2} + \ldots + \alpha_{p+1} y_{t-p-1} + e_t$$

The characteristic equation follows:

$$m^{p+1} - \alpha_1 m^p - \alpha_2 m^{p-1} - \ldots - \alpha_{p+1} = 0$$

If all the characteristic roots are less than 1 in absolute value, y_t, is stationary. y_t is nonstationary if there is a unit root. If there is a unit root, the sum of the autoregressive parameters is 1, and therefore you can test for a unit root by testing whether the sum of the autoregressive parameters is 1. The no-intercept model is parameterized as follows.

$$\nabla y_t = \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \ldots + \theta_p \nabla y_{t-p} + e_t$$

In the equation above, the following relationships apply:

$$\nabla y_t = y_t - y_{t-1}$$

and

$$\delta = a_1 + \ldots + \alpha_{p+1} - 1$$

$$\theta_k = -\alpha_{k+1} - \ldots - \alpha_{p+1}$$

The estimators are obtained by regressing ∇y_t on y_{t-1}, $\nabla y_{t-1}, \ldots, \nabla y_{t-p}$. The t statistic of the ordinary least squares estimator of δ is the test statistic for the unit root test.

If the type argument value specifies a test for a nonzero mean (intercept case), the autoregressive model includes a mean term α_0. If the *type* argument value specifies a test for a time trend, the model also includes a time trend term and the model is as follows:

$$\nabla y_t = \alpha_0 + \gamma t + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \ldots + \theta_p \nabla y_{t-p} + e_1$$

For testing for a seasonal unit root, consider the multiplicative model.

$$(1 - \alpha_d \mathrm{B}^d)(1 - \theta_1 \mathrm{B} - \ldots - \theta_p \mathrm{B}^p) y_t = e_t$$

Let $\nabla^d y_t \equiv y_t - y_{t-d}$. The test statistic is calculated in the following steps:

1. Regress $\nabla^d y_t$ on $\nabla^d y_{t-1} \ \ldots \ \nabla^d y_{t-p}$ to obtain the initial estimators $\hat{\theta}_i$ and compute residuals $\hat{e}_t$. Under the null hypothesis that $\alpha_d = 1$, $\hat{\theta}_i$ are consistent estimators of θ_i.

2. Regress $\hat{e}_t$ on $(1 - \hat{\theta}_1 \mathrm{B} - \ldots - \hat{\theta}_p \mathrm{B}^p) y_{t-d}$, $\nabla^d y_{t-1}, \ldots, \nabla^d y_{t-p}$ to obtain estimates of $\delta = \alpha_d - 1$ and $\theta_i - \hat{\theta}_i$.

The *t* ratio for the estimates of δ that are produced by the second step is used as a test statistic for testing for a seasonal unit root. The estimates of θ_i are obtained by adding the estimates of $\theta_i - \hat{\theta}_i$ from the second step to $\hat{\theta}_i$ from the first step.

The series $(1 - \mathrm{B}^d)y_t$ is assumed to be stationary, where *d* is the value of the third argument to the PROBDF function.

If the series is an ARMA process, then a large value of *p* might be desirable in order to obtain a reliable test statistic. To determine an appropriate value for *p*, see Said and Dickey (1984)[1].

Test Statistics

The Dickey-Fuller test is used to test the null hypothesis that the time series exhibits a lag *d* unit root against the alternative of stationarity. The PROBDF function computes the probability of observing a test statistic more extreme than *x* under the assumption that the null hypothesis is true. You should reject the unit root hypothesis when PROBDF returns a small (significant) probability value.

Consider the Dickey-Fuller regression first. There are several versions of the Dickey-Fuller test. The PROBDF function supports six versions, as selected by the *type* argument. Specify the *type* value that corresponds to how you calculated the test statistic *x*.

The last two characters of the *type* value specify the type of regression model that is used to compute the Dickey-Fuller test statistic. The meaning of the last two characters of the *type* value are as follows:

SM
: specifies a single mean or intercept case. The test statistic *x* is assumed to be computed from the following regression model:

$$y_t = \mu + \alpha y_{t-1} + e_t$$

TR
: specifies the intercept and deterministic time trend case. The test statistic *x* is assumed to be computed from the following regression model:

$$y_t = \mu + \gamma t + \alpha y_{t-1} + e_t$$

ZM
: specifies the zero mean or no-intercept case. The test statistic *x* is assumed to be computed from the following regression model:

$$y_t = \alpha y_{t-1} + e_t$$

The first character of the *type* value specifies whether the regression test statistic or the studentized test statistic is used. Let $\hat{\alpha}$ be the estimated regression coefficient for the lag of the series, and let se_α be the standard error of $\hat{\alpha}$. The meaning of the first character of the *type* value is as follows:

R
: specifies the regression-coefficient-based test statistic. The test statistic follows:

1. Said, S. E., and Dickey, D. A. (1984). "Testing for Unit Roots in ARMA Models of Unknown Order." Biometrika 71:599–607.

$$\rho = n(\widehat{\alpha} - 1)$$

S

specifies the studentized test statistic. The test statistic follows:

$$DF_t = \frac{(\widehat{\alpha} - 1)}{se_\alpha}$$

The equation for the *type* value of R is also called ρ-test. The equation for the *type* value of S is also called τ-test. For the zero mean model, the asymptotic distributions of the Dickey-Fuller test statistics follow:

$$n(\widehat{\alpha} - 1) \Rightarrow \left(\int_0^1 W(r)\, \mathbb{d}W(r)\right) \left(\int_0^1 W(r)^2 dr\right)^{-1}$$

$$DF_\tau \Rightarrow \left(\int_0^1 W(r)\, \mathbb{d}W(r)\right) \left(\int_0^1 W(r)^2\, \mathbb{d}r\right)^{-\frac{1}{2}}$$

For the constant mean model, the asymptotic distributions follow:

$$n(\widehat{\alpha} - 1) \Rightarrow \left([W(1)^2 - 1]/2 - W(1)\int_0^1 W(r)\, \mathbb{d}r\right) \left(\int_0^1 W(r)^2\, \mathbb{d}r - \left(\int_0^1 W(r)\, \mathbb{d}r\right)^2\right)^{-1}$$

$$DF\tau \Rightarrow \left([W(1)^2 - 1]/2 - W(1)\int_0^1 W(r)\, \mathbb{d}r\right) \left(\int_0^1 W(r)^2\, \mathbb{d}r - \left(\int_0^1 W(r)\, \mathbb{d}r\right)^2\right)^{-1/2}$$

For the trend model, the asymptotic distributions follow:

$$n(\widehat{\alpha} - 1) \Rightarrow \left[W(r)dW + 12 \left(\int_0^1 rW(r)\, \mathbb{d}r - \tfrac{1}{2}\int_0^1 W(r)\, \mathbb{d}r\right) \left(\int_0^1 W(r)\, \mathbb{d}r - \tfrac{1}{2}W(1)\right) - W(1)\int_0^1 W(r)\, \mathbb{d}r\right] D^1$$

$$DF\tau \Rightarrow \left[W(r)dW + 12 \left(\int_0^1 rW(r)\, \mathbb{d}r - \tfrac{1}{2}\int_0^1 W(r)\, \mathbb{d}r\right) \left(\int_0^1 W(r)\, \mathbb{d}r - \tfrac{1}{2}W(1)\right) - W(1)\int_0^1 W(r)\, \mathbb{d}r\right] D^{1/2}$$

The following equation applies to the equations that are shown above:

$$D = \int_0^1 W(r)^2\, \mathbb{d}r - 12\left(\int_0^1 rW(r)dr\right)^2 + 12 \int_0^1 W(r)\, \mathbb{d}r \int_0^1 rW(r)\, \mathbb{d}r - 4\left(\int_0^1 W(r)dr\right)^2$$

For more information about the Dickey-Fuller test null distribution, see Dickey and Fuller (1979), Dickey, Hasza, and Fuller (1984), and Hamilton (1994). The preceding formulas are for the basic Dickey-Fuller test. The PROBDF function can also be used for the augmented Dickey-Fuller test, in which the error term is modeled as an autoregressive process. However, the test statistic is computed somewhat differently for the augmented Dickey-Fuller test. For the nonseasonal augmented Dickey-Fuller test, the test statistics can have one of the two forms similar to Dickey-Fuller test. One of the forms is the OLS *t* value, $\frac{\widehat{\alpha} - 1}{sd(\alpha)}$, and the other form is $\frac{n(\widehat{\alpha} - 1)}{1 - \widehat{\alpha}_1 - \ldots - \widehat{\alpha}_p}$

Example

In the following program, the table Test contains 104 observations of the time series variable *Y*. The program tests the null hypothesis that there exists a lag 4 seasonal unit root in the Y series. The following program illustrates how to perform the single-mean Dickey-Fuller regression coefficient test using PROC REG and the PROBDF function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test1 (overwrite=yes);
   set test;
   y4 = lag4(y);
end;
enddata;
run;
quit;

proc reg data=test1 outest=alpha;
   model y = y4 / noprint;
run;

proc ds2;
data _null_;
   dcl double x p;
   method run();
      set alpha;
      x = 100 * ( y4 - 1 );
      p = probdf( x, 100, 4, 'RSM' );
      put p= pvalue5.3;
   end;
enddata;
run;
quit;
```

To perform the augmented Dickey-Fuller test, regress the differences of the series on lagged differences and on the lagged value of the series, and compute the test statistic from the regression coefficient for the lagged series. The following program illustrates how to perform the single-mean augmented Dickey-Fuller studentized test for a simple unit root using PROC REG and the PROBDF function:

```
proc ds2;
data test1 (overwrite=yes);
   set test;
   yl  = lag(y);
   yd  = dif(y);
   yd1 = lag1(yd); yd2 = lag2(yd);
   yd3 = lag3(yd); yd4 = lag4(yd);
 enddata;
run;
quit;

proc reg data=test1 outest=alpha covout;
   model yd = yl yd1-yd4 / noprint;
```

```
run;

proc ds2;
data _null_;
   dcl double a x p;
   method run();
      set alpha;
      retain a;
      if _type_ = 'PARMS' then
         a = yl;
      if _type_ = 'COV' & _NAME_ = 'Y1' then do;
         x = a / sqrt(yl);
         p = probdf( x, 99, 1, "SSM" );
         put p= ;
   end;
enddata;
run;
quit;
```

The %DFTEST macro provides an easier way to perform the Dickey-Fuller tests. The following statements perform the same tests as the preceding example:

```
%dftest(test, y, ar=4);
%put p=&dftest;
```

Note: When DS2 runs outside of SAS, such as in the SAS Federation Server and in grid computing environments, the SAS macro facility is not available and DS2 programs with macros fail to compile.

PROBF Function

Returns the probability from an *F* distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBF(*x*, *ndf*, *ddf*[, *nc*])

Required Arguments

x

is a numeric random variable.

Range $x \geq 0$

Data type DOUBLE

ndf
is a numeric numerator degrees of freedom parameter.

Range *ndf* > 0

Data type DOUBLE

ddf
is a numeric denominator degrees of freedom parameter.

Range *ddf* > 0

Data type DOUBLE

Optional Argument

nc
is an optional numeric noncentrality parameter.

Range *nc* ≥ 0

Data type DOUBLE

Details

The PROBF function returns the probability that an observation from an *F* distribution, with numerator degrees of freedom *ndf*, denominator degrees of freedom *ddf*, and noncentrality parameter *nc*, is less than or equal to *x*. The PROBF function accepts noninteger degrees of freedom parameters *ndf* and *ddf*. If the optional parameter *nc* is not specified or has the value 0, the value returned is from the central *F* distribution.

The significance level for an *F* test statistic is given by the following equation.

```
p=1-probf(x,ndf,ddf);
```

Example

The following program illustrates the PROBF function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double x;
   method run();
      x=probf(3.32,2,3);
```

```
      put x= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.82639336022431
```

PROBGAM Function

Returns the probability from a gamma distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBGAM(*x*, *a*)

Required Arguments

x

is a numeric random variable.

Range $x \geq 0$

Data type DOUBLE

a

is a numeric shape parameter.

Data type DOUBLE

Details

The PROBGAM function returns the probability that an observation from a gamma distribution, with shape parameter *a*, is less than or equal to *x*.

Example

The following program illustrates the PROBGAM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   method run();
      x=probgam(1,3);
      put x= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.08030139707139
```

PROBHYPR Function

Returns the probability from a hypergeometric distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBHYPR(*N*, *K*, *n*, *x*[, *r*])

Required Arguments

N

is a population size parameter. This argument must be a whole number.

Range $N \geq 1$

Data type DOUBLE

K

is the number of items in the category of interest parameter. This argument must be a whole number.

Range $0 \leq K \leq N$

Data type DOUBLE

n

is the sample size parameter. This argument must be a whole number.

Range $0 \le n \le N$

Data type DOUBLE

x

is the random variable. This argument must be a whole number.

Range $max(0, K + n - N) \le x \le min(K,n)$

Optional Argument

r

is a numeric odds ratio parameter.

Range $r \ge 0$

Data type DOUBLE

Details

The PROBHYPR function returns the probability that an observation from an extended hypergeometric distribution, with population size *N*, number of items *K*, sample size *n*, and odds ratio *r*, is less than or equal to *x*. If the optional parameter *r* is not specified or is set to 1, the value returned is from the usual hypergeometric distribution.

Example

The following program illustrates the PROBHYPR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method run();
      x=probhypr(200,50,10,2);
      put x= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.52367340812173
```

PROBIT Function

Returns a quantile from the standard normal distribution.

Category:	Quantile
Returned data type:	DOUBLE

Syntax

PROBIT(*p*)

Required Argument

p
is a numeric probability.

Range	$0 < p < 1$
Data type	DOUBLE

Details

The PROBIT function returns the p^{th} quantile from the standard normal distribution. The probability that an observation from the standard normal distribution is less than or equal to the returned quantile is *p*.

CAUTION
The result could be truncated to lie between -8.222 and 7.941.

Note: PROBIT is the inverse of the PROBNORM function.

Example

The following program illustrates the PROBIT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x y;
   method run();
      x=probit(.025);
      put x= ;
      y=probit(1.e-7);
      put y= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=-1.95996398454005
y=-5.19933758219281
```

PROBMC Function

Returns a probability or a quantile from various distributions for multiple comparisons of means.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBMC(*distribution*, *q*, *prob*, *df*, *nparms*[, *parameters*])

Required Arguments

distribution

is a character constant, variable, or expression that evaluates or can be coerced to a character string and that identifies the distribution. The following distributions are valid: ANOM (Analysis of Means), DUNNETT1, DUNNETT2, MAXMOD (Maximum Modulus), PARTRANGE (Partitioned Range), RANGE (Studentized Range), and WILLIAMS.

is a character constant, variable, or expression that identifies the distribution. The following distributions are valid:

Distribution	Argument
Analysis of Means	ANOM
One-sided Dunnett	DUNNETT1
Two-sided Dunnett	DUNNETT2
Maximum Modulus	MAXMOD
Partitioned Range	PARTRANGE
Studentized Range	RANGE
Williams	WILLIAMS

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

q
is the quantile from the distribution.

Restriction Either *q* or *prob* can be specified, but not both.

Data type DOUBLE

prob
is the left probability from the distribution.

Restriction Either *prob* or *q* can be specified, but not both.

Data type DOUBLE

df
is the degrees of freedom.

Note: A missing value is interpreted as an infinite value.

nparms
is the number of treatments.

Data type DOUBLE

Note For DUNNETT1 and DUNNETT2, the control group is not counted.

Optional Argument

parameters
is a set of *nparms* parameters that must be specified to handle the case of unequal sample sizes. The meaning of *parameters* depends on the value of

distribution. If *parameters* is not specified, equal sample sizes are assumed, which is usually the case for a null hypothesis.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Overview

The PROBMC function returns the probability or the quantile from various distributions with finite and infinite degrees of freedom for the variance estimate.

The *prob* argument is the probability that the random variable is less than *q*. Therefore, *p*-values can be computed as 1– *prob*. For example, to compute the critical value for a 5% significance level, set *prob*= 0.95. The precision of the computed probability is $O(10^{-8})$ (absolute error); the precision of computed quantile is $O(10^{-5})$.

Note: The studentized range is not computed for finite degrees of freedom and unequal sample sizes.

Note: Williams' test is computed only for equal sample sizes.

Formulas and Parameters

The equations listed here define expressions that are used in equations that relate the probability, *prob*, and the quantile, *q*, for different distributions and different situations within each distribution. For these equations, let *v* be the degrees of freedom, *df*.

$$d\mu_\nu(x) = \frac{\nu^{\frac{\nu}{2}}}{\Gamma\left(\frac{\nu}{2}\right)2^{\frac{\nu}{2}-1}} x^{\nu-1}\varepsilon^{-\frac{\nu x^2}{2}}dx$$

$$\phi(x) = \frac{1}{\sqrt{2\,\pi}}\varepsilon^{-\frac{x^2}{2}}$$

$$\Phi(x) = \int_{-\infty}^{x} \phi(u)du$$

Computing the Analysis of Means

Analysis of Means (ANOM) applies to data that is organized as *k* (Gaussian) samples, the i^{th} sample being of size n_i. Let $I = \sqrt{-1}$. The distribution function [1, 2, 3, 4, 5] is the CDF for the maximum absolute of a *k*-dimensional multivariate T vector, with ν degrees of freedom, and an associated correlation matrix $\rho_{ij} = -\alpha_i\alpha_j$. This equation can be written as follows.

$$prob = r(|t_1| < h, |t_2| < h, ..., |t_k| < h)$$
$$= \int_0^\infty \left\{ \int_0^\infty \prod_{j=0}^{j=k} g(sh, y, \alpha_j)\phi(y)dy \right\} d\mu_\nu(s)$$

The following relationship applies to the preceding equation:

$$g(sh, y, \alpha_j) = \Phi\left(\frac{sh - y\alpha_j}{\sqrt{1+\alpha_j^2}}\right) - \Phi\left(\frac{-sh - y\alpha_j}{\sqrt{1+\alpha_j^2}}\right)$$

In this equation, $\Gamma(.)$, $\phi(.)$, and $\Phi(.)$, are the gamma function, the density, and the CDF from the standard normal distribution, respectively.

For $\nu = \infty$, the distribution reduces to this equation.

$$r(|t_1| < h, |t_2| < h, ..., |t_k| < h) = \int_0^\infty \prod_{j=0}^{j=k} g(h, y, \alpha_j)\phi(y)dy$$

The following relationship applies to the preceding equation:

$$g(h, y, \alpha_j) = \Phi\left(\frac{h - y\alpha_j}{\sqrt{1+\alpha_j^2}}\right) - \Phi\left(\frac{-h - y\alpha_j}{\sqrt{1+\alpha_j^2}}\right)$$

For the balanced case, the distribution reduces to the following equation:

$$r(|t_1| < h, |t_2| < h, ..., |t_n| < h) = \int_0^\infty f(h, y, \rho)^n \phi(y)dy$$

The following relationships apply to the preceding equation:

$$f(h, y, \rho) = \Phi\left(\frac{h - y\sqrt{\rho}}{\sqrt{1+\rho}}\right) - \Phi\left(\frac{-h - y\sqrt{\rho}}{\sqrt{1+\rho}}\right)$$

$$\rho = \frac{1}{n-1}$$

Here is the syntax for this distribution:

x=probmc('anom', q, p, nu, n[, alpha$_1$, ..., alpha$_n$]);

Arguments

x
is a numeric value with the returned result.

q
is a numeric value that denotes the quantile.

p
is a numeric value that denotes the probability. One of *p* and *q* must be missing.

nu
is a numeric value that denotes the degrees of freedom.

n
is a numeric value that denotes the number of samples.

alpha$_i$, i = 1, ...,k

are optional numeric values denoting the alpha values from the first equation of this distribution. See "Computing the Analysis of Means" on page 1010.

Many-One *t*-Statistics: Dunnett's One-Sided Test

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with finite degrees of freedom. The *parameters* are $\lambda_1, ..., \lambda_k$, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \Phi\left(\frac{\lambda_i y + qx}{\sqrt{1-\lambda_i^2}}\right) dy\, du_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with finite degrees of freedom. No *parameters* are passed $\left(\lambda = \sqrt{\frac{1}{2}}\right)$, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y)[\Phi(y + \sqrt{2qx})]^k dy\, du_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with infinite degrees of freedom. The *parameters* are $\lambda_1, ..., \lambda_k$, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \Phi\left(\frac{\lambda_i y + q}{\sqrt{1-\lambda_i^2}}\right) dy$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with infinite degrees of freedom. No *parameters* are passed $\left(\lambda = \sqrt{\frac{1}{2}}\right)$, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \int_{-\infty}^{\infty} \phi(y)[\Phi(y + \sqrt{2q})]^k dy$$

Many-One *t*-Statistics: Dunnett's Two-sided Test

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with finite degrees of freedom. The *parameters* are $\lambda_1, ..., \lambda_k$, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \left[\Phi\left(\frac{\lambda_i y + qx}{\sqrt{1-\lambda_i^2}}\right) - \Phi\left(\frac{\lambda_i y - qx}{\sqrt{1-\lambda_i^2}}\right)\right] dy\, du_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with finite degrees of freedom. No *parameters* are passed, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_0^{\infty} \int_{-\infty}^{\infty} \phi(y)[\Phi(y + \sqrt{2qx}) - \Phi(y - \sqrt{2qx})]^k dy\, du_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with infinite degrees of freedom. The *parameters* are $\lambda_1, ..., \lambda_k$, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{k} \left[\Phi\left(\frac{\lambda_i y + q}{\sqrt{1-\lambda_i^2}} \right) - \Phi\left(\frac{\lambda_i y - q}{\sqrt{1-\lambda_i^2}} \right) \right] dy$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with infinite degrees of freedom. No *parameters* are passed, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \int_{-\infty}^{\infty} \phi(y)[\Phi(y+\sqrt{2q}) - \Phi(y-\sqrt{2q})]^k dy$$

Computing the Partitioned Range

RANGE applies to the distribution of the studentized range for *n* group means. PARTRANGE applies to the distribution of the partitioned studentized range. Let the *n* groups be partitioned into *k* subsets of size $n_1 + \ldots + n_k = n$. Then the partitioned range is the maximum of the studentized ranges in the respective subsets. The studentization factor is the same in all cases.

$$prob = \int_{0}^{\infty} \prod_{i=1}^{i=k} \left(\int_{-\infty}^{\infty} k\phi(y)(\Phi(y) - \Phi(y-qx))^{k-1} dy \right)^{n_i} d\mu_\nu(x)$$

Here is the syntax for this distribution:

x=probmc('partrange', q, p,nu, k, n_1,...,n_k);

Arguments

x
is a numeric value with the returned result (either the probability or the quantile).

q
is a numeric value that denotes the quantile.

p
is a numeric value that denotes the probability. One of *p* and *q* must be missing.

nu
is a numeric value that denotes the degrees of freedom.

k
is a numeric value that denotes the number of groups.

n_i i=1,...,k
are optional numeric values that denote the *n* values from the equation in this distribution. See "Computing the Partitioned Range" on page 1013.

The Studentized Range

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with finite degrees of freedom. No *parameters* are passed, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_{0}^{\infty} \int_{-\infty}^{\infty} k\phi(y)[\Phi(y) - \Phi(y-qx)]^{k-1} dy\, du_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with infinite degrees of freedom. The *parameters* are σ_1, ..., σ_k, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \int_{-\infty}^{\infty} \sum_{j=1}^{k} \left\{ \prod_{i=1}^{k} \left[\Phi\left(\frac{y}{\sigma_i}\right) - \Phi\left(\frac{y-q}{\sigma_i}\right) \right] \right\} \phi\left(\frac{y}{\sigma_j}\right) \frac{1}{\sigma_j} dy$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with infinite degrees of freedom. No *parameters* are passed, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \int_{-\infty}^{\infty} k\phi(y)[\Phi(y) - \Phi(y-q)]^{k-1} dy$$

The Studentized Maximum Modulus

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with finite degrees of freedom. The *parameters* are σ_1, ..., σ_k, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_{0}^{\infty} \prod_{i=1}^{k} \left[2\Phi\left(\frac{qx}{\sigma_i}\right) - 1 \right] d\mu_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with finite degrees of freedom. No *parameters* are passed, the value of *nparms* is set to *k*, and the value of *df* is set to *v*. The equation follows:

$$prob = \int_{0}^{\infty} [2\Phi(qx) - 1]^k d\mu_\nu(x)$$

- This case relates the probability, *prob*, and the quantile, *q*, for the unequal case with infinite degrees of freedom. The *parameters* are σ_1, ..., σ_k, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = \prod_{i=1}^{k} \left[2\Phi\left(\frac{q}{\sigma_i}\right) - 1 \right]$$

- This case relates the probability, *prob*, and the quantile, *q*, for the equal case with infinite degrees of freedom. No *parameters* are passed, the value of *nparms* is set to *k*, and the value of *df* is set to missing. The equation follows:

$$prob = [2\Phi(q) - 1]^k$$

Williams' Test

PROBMC computes the probabilities or quantiles from the distribution defined in Williams (1971, 1972). See ""References"" in *SAS Functions and CALL Routines: Reference*.The need for the Williams' Test arises when you compare the dose treatment means with a control mean to determine the lowest effective dose of treatment.

Note: Williams' Test is computed only for equal sample sizes.

Let $X_1, X_2, ..., X_k$ be identical independent N(0,1) random variables. Let Y_k denote their average given by the following equation.

$$Y_k = \frac{X_1 + X_2 + ... + X_k}{k}$$

It is required to compute the distribution of the following value.

$$(Y_k - Z)/S$$

Arguments

***Y*$_k$**
is as defined previously.

Z
is an N(0,1) independent random variable.

S
is such that ½vS^2 is a χ^2 variable with v degrees of freedom.

As described in Williams (1971), the full computation is extremely lengthy, and is carried out in three stages. See ""References"" in *SAS Functions and CALL Routines: Reference*.

1 Compute the distribution of Y_k. It is the fundamental (expensive) part of this operation and it can be used to find both the density and the probability of Y_k. Let U_i be defined in this equation.

$$U_i = \frac{X_1 + X_2 + ... + X_i}{i},\ i = 1, 2, ..., k$$

You can write a recursive expression for the probability of $Y_k > d$. The value of d can be any real number.

$$\begin{aligned}\Pr(Y_k > d) &= \Pr(U_1 > d)\\ &\quad +\Pr(U_2 > d, U_1 < d)\\ &\quad +\Pr(U_3 > d, U_2 < d, U_1 < d)\\ &\quad +\ldots\\ &\quad +\Pr(U_k > d, U_{k-1} < d, \ldots, U_1 < d)\\ &= \Pr(Y_{k-1} > d) + \Pr(X_k + (k-1)U_{k-1} > kd)\end{aligned}$$

To compute this probability, start from an N(0,1) density function.

$$D(U_1 = x) = \phi(x)$$

And recursively compute the convolution.

$$D(U_k = x, U_{k-1} < d, \ldots, U_1 < d) =$$
$$\int_{-\infty}^{d} D(U_{k-1} = y, U_{k-2} < d, \ldots, U_1 < d)(k-1)\phi(kx - (k-1)y)dy$$

From this sequential convolution, it is possible to compute all the elements of the recursive equation for $\Pr(Y_k < d)$, shown previously.

2 Compute the distribution of $Y_k - Z$. This computation involves another convolution to compute the probability.

$$\Pr((Y_k - Z) > d) = \int_{-\infty}^{\infty} \Pr(Y_k > \sqrt{2d} + y)\phi(y)dy$$

3 Compute the distribution of $(Y_k - Z)/S$. This computation involves another convolution to compute the probability.

$$\Pr((Y_k - Z) > tS) = \int_{0}^{\infty} \Pr((Y_k - Z) > ty)d\mu_\nu(y)$$

The third stage is not needed when v = ∞. Due to the complexity of the operations, this lengthy algorithm is replaced by a much faster one when $k \le 15$ for both finite and infinite degrees of freedom v. For $k \ge 16$, the lengthy computation is carried out. It is extremely expensive and very slow due to the complexity of the algorithm.

Comparisons

The MEANS statement in the GLM Procedure of SAS/STAT Software computes the following tests:

- Dunnett's one-sided test
- Dunnett's two-sided test
- Studentized Range

Examples

Example 1: Computing Probabilities By Using PROBMC

The following program shows how to compute probabilities.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double par[5];
   dcl double df q prob;
   dcl char(20) test[3];
   dcl int i;
   method run();
      par := (.5 .51 .55 .45 .2);
      df = 40;
      q = 1;
      test := ('dunnett1' 'dunnett2' 'maxmod');
      do i = 1 to dim(test);
         prob=probmc(test[i], q, ., df, 5, par[1], par[2], par[3],
par[4],
```

```
            par[5]);
         put test[i] $10. df q e18.13 prob e18.13;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
dunnett1  40  1.00000000000E+00 4.82992196083E-01
dunnett2  40  1.00000000000E+00 1.64023105316E-01
maxmod    40  1.00000000000E+00 8.02784203408E-01
```

Example 2: Computing the Analysis of Means

The following program shows how to compute the analysis of means.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double q1 q2 q3 q4;
   method run();
      q1=probmc('anom',.,0.9,.,20);
      put q1=;
      q2=probmc('anom',.,0.9,20,5,0.1,0.1,0.1,0.1,0.1);
      put q2=;
      q3=probmc('anom',.,0.9,20,5,0.5,0.5,0.5,0.5,0.5);
      put q3=;
      q4=probmc('anom',.,0.9,20,5,0.1,0.2,0.3,0.4,0.5);
      put q4=;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
q1=2.78950610163346
q2=2.45499619666786
q3=2.45499619666786
q4=2.45323199941123
```

Example 3: Computing the Partitioned Range

The following program shows how to compute the partitioned range.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double q1 q2;
   method run();
```

```
        q1=probmc('partrange',.,0.9,.,4,3,4,5,6);
        put q1=;
        q2=probmc('partrange',.,0.9,12,4,3,4,5,6);
        put q2=;
    end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
q1=4.1022397989482
q2=4.7888626337511
```

Example 4: Computing Williams' Test

In the following program, a substance has been tested at seven levels in a randomized block design of eight blocks. The observed treatment means are as follows:

Treatment	Mean
X_0	10.4
X_1	9.9
X_2	10.0
X_3	10.6
X_4	11.4
X_5	11.9
X_6	11.7

The mean square, with (7 – 1)(8 – 1) = 42 degrees of freedom, is $s^2 = 1.16$.

Determine the maximum likelihood estimates M_i through the averaging process.

- Because $X_0 > X_1$, form $X_{0,1} = (X_0 + X_1)/2 = 10.15$.
- Because $X_{0,1} > X_2$, form $X_{0,1,2} = (X_0 + X_1 + X_2)/3 = (2X_{0,1} + X_2)/3 = 10.1$.
- $X_{0,1,2} < X_3 < X_4 < X_5$
- Because $X_5 > X_6$, form $X_{5,6} = (X_5 + X_6)/2 = 11.8$.

Now the order restriction is satisfied.

The maximum likelihood estimates under the alternative hypothesis are:

- $M_0 = M_1 = M_2 = X_{0,1,2} = 10.1$

- $M_3 = X_3 = 10.6$
- $M_4 = X_4 = 11.4$
- $M_5 = M_6 = X_{5,6} = 11.8$

Now compute $t = (11.8 - 10.4)/\sqrt{2s^2/8} = 2.60$, and the probability that corresponds to $k = 6$, v = 42, and $t = 2.60$ is .9924467341, which shows strong evidence that there is a response to the substance.

You can also compute the quantiles for the upper 5% and 1% tails, as shown in the following program.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double prob quant5 quant1;
   method run();
      prob=probmc('WILLIAMS',2.6,.,42,6);
      put prob=;
      quant5=probmc('WILLIAMS',.,.95,42,6);
      put quant5=;
      quant1=probmc('WILLIAMS',.,.99,42,6);
      put quant1= ;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
prob=0.99244668715827
quant5=1.80656253603894
quant1=2.49090827298707
```

PROBMED Function

Computes cumulative probabilities for the sample median.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBMED(*n*, *x*)

Required Arguments

n

specifies the sample size.

Data type DOUBLE

x

is the point of interest. That is, the PROBMED function calculates the probability that the median is less than or equal to *x*.

Data type DOUBLE

Details

The PROBMED function computes the probability that the sample median is less than or equal to *x* for a sample of *n* independent, standard normal random variables (mean 0, variance 1).

Let *n* represent the sample size, and $x_{(i)}$ represents the *i*th order statistic. Then, when *n* is odd, the function makes the following calculation:

$$\Pr\left[X_{((n+1)/2)} \leq x\right] = \mathrm{I}_{\Phi(x)}\left(\frac{n+1}{2}, \frac{n+1}{2}\right)$$

The following equations refer to the preceding equation:

$$I_p(a,b) = \frac{I}{B(a,b)} \int_0^p t^{a-1}(I-t)^{b-1} dt$$

In the equation $B(a,b) = \Gamma(a)\Gamma(b)/\Gamma(a+b)$, $\Gamma(.)$ is the gamma function. If *n* is even, the PROBMED function performs the following calculation:

$$\Pr\left[\frac{X_{(n/2)} + X_{((n/2)+1)}}{2} \le x\right] =$$

$$\frac{2}{B(\frac{n}{2},\frac{n}{2})} \int_{-\infty}^{x} \{[I-\Phi(u)]^{n/2} - [I-\Phi(2x-u)]^{n/2}\}[\Phi(u)]^{(n/2)-1}\phi(u)du$$

In this equation, $B(n/2,\ n/2) = [\Gamma(n/2)]^2/\Gamma(n)$, and $\Phi(.)$ and $\phi(.)$ are the standard normal cumulative distribution function and density function, respectively.

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double b;
   method run();
      b=probmed(5,-0.1);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.42563808966747
```

PROBNEGB Function

Returns the probability from a negative binomial distribution.

Category:	Probability
Returned data type:	DOUBLE

Syntax

PROBNEGB(*p*, *n*, *m*)

Required Arguments

p

is a numeric probability of success parameter.

Range $0 \leq p \leq 1$

Data type DOUBLE

n

is the number of successes parameter. This argument must be a whole number.

Range $n \geq 1$

Data type DOUBLE

m

is the random variable, the number of failures. This argument must be a positive, whole number.

Range $m \geq 0$

Data type DOUBLE

Details

The PROBNEGB function returns the probability that an observation from a negative binomial distribution, with probability of success *p* and number of successes *n*, is less than or equal to *m*.

To compute the probability that an observation is equal to a given value *m*, compute the difference of two probabilities from the negative binomial distribution for *m* and *m*−1.

Example

The following program illustrates the PROBNEGB function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
```

```
      x=probnegb(0.5,2,1);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.5
```

PROBNORM Function

Returns the probability from the standard normal distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBNORM(*x*)

Required Argument

x
is a numeric random variable.

Data type DOUBLE

Details

The PROBNORM function returns the probability that an observation from the standard normal distribution is less than or equal to *x*.

Note: PROBNORM is the inverse of the PROBIT function.

Example

The following program illustrates the PROBNORM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=probnorm(1.96);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.97500210485177
```

PROBT Function

Returns the probability from a *t* distribution.

Category: Probability

Returned data type: DOUBLE

Syntax

PROBT(*x*, *df*[, *nc*])

Required Arguments

x
is a numeric random variable.

Data type DOUBLE

df
is a numeric degrees of freedom parameter.

Range *df* > 0

Data type DOUBLE

Optional Argument

nc
is a numeric noncentrality parameter.

Data type DOUBLE

Details

The PROBT function returns the probability that an observation from a Student's *t* distribution, with degrees of freedom *df* and noncentrality parameter *nc*, is less than or equal to *x*. This function accepts a noninteger degree of freedom parameter *df*. If the optional parameter, *nc*, is not specified or has the value 0, the value that is returned is from the central Student's *t* distribution.

The significance level of a two-tailed *t* test is given by the following equation.

```
p=(1-probt(abs(x),df))*2;
```

Example

The following program illustrates the PROBT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=probt(0.9,5);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.79531439982768
```

PROGRAMBLOCKLINENUMBER Function

Returns the line number of the current statement starting from the beginning of the current program block.

Category: Special

Returned data type: INTEGER

Syntax

PROGRAMBLOCKLINENUMBER()

Without Arguments

The PROGRAMBLOCKLINENUMBER() function has no arguments.

Details

The ProgramBlockLineNumber function returns the line number of the current statement, offset from the beginning of the current package, thread, or data block. Program block line numbers start with 1 at the PACKAGE, THREAD, or DATA statement that starts the program block and continue in sequence until the ENDPACKAGE, ENDTHREAD, or ENDDATA statement that ends the program block.

Example

The following program illustrates the PROGRAMBLOCKLINENUMBER function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
resetline;
proc ds2;
thread testthread / overwrite=yes;
   dcl char a;
   dcl int threadline;
   method init();
      a = 'apple';
      threadline = programblocklinenumber();
      put threadline=;
   end;
endthread;

data _null_;
   dcl thread testthread t();
   dcl int dataline;
   dcl char b;
   method init();
      b = 'banana';
      dataline = programblocklinenumber();
      put dataline=;
   end;
   method run();
      set from t threads = 1;
  end;
enddata;
```

```
run;
quit;
```

SAS writes the following output to the log.

```
78   resetline;
1    proc ds2;
2
3    thread testthread / overwrite=yes;
4      dcl char a;
5      dcl int threadline;
6      method init();7        a = 'apple';
8        threadline = programblocklinenumber();
9       put threadline=;
10     end;
11   endthread;
12
13   data _null_;
14   dcl thread testthread t();
15   dcl int dataline;
16   dcl char b;
17     method init();
18       b = 'banana';
19       dataline = programblocklinenumber();
20       put dataline=;
21     end;
22
23     method run();
24      set from t threads = 1;
25     end;
26   enddata;
27   run;
dataline=7

threadline=6
```

"SASLOGLINENUMBER Function" on page 1116

PROGRAMBLOCKLNAME Function

Returns the name of the current programming block.

Category:	Special
Returned data type:	CHAR

Syntax

PROGRAMBLOCKNAME()

Without Arguments

The PROGRAMBLOCKNAME() function has no arguments.

Details

The ProgramBlockName function returns the name of the current program block. For package and thread program blocks, the user-defined name of the package or thread is returned. For data program blocks, 'block' is returned, so the program block type and program block name is 'data block'.

Example

The following program illustrates the PROGRAMBLOCKNAME function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
resetline;
proc ds2;

thread testthread / overwrite=yes;
   dcl char a;
   dcl varchar(100) threadname;
   method init();
      a = 'apple';
      threadname = programblockname();
      put threadname=;
   end;
endthread;

data _null_;
   dcl thread testthread t();
   dcl varchar(100) dataname;
   dcl char b;
   method init();
      b = 'banana';
      dataname = programblockname();
      put dataname=;
   end;

   method run();
      set from t threads = 1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
78   resetline;
1    proc ds2;
2
3    thread testthread / overwrite=yes;
4      dcl char a;
5      dcl varchar(100) threadname;
6      method init();
7       a = 'apple';
8        threadname = programblockname();
9       put threadname=;
10     end;
11   endthread;
12
13   data _null_;
14   dcl thread testthread t();
15   dcl varchar(100) dataname;
16   dcl char b;
17     method init();
18       b = 'banana';
19       dataname = programblockname();
20     put dataname=;
21     end;
22
23     method run();
24      set from t threads = 1;
25     end;
26   enddata;
27   run;
dataname=block
threadname=testthread
```

See Also

"PROGRAMBLOCKTYPE Function" on page 1029

PROGRAMBLOCKTYPE Function

Returns the type of the current programming block.

Category:	Special
Returned data type:	CHAR

Syntax

PROGRAMBLOCKTYPE()

Without Arguments

The PROGRAMBLOCKTYPE() function has no arguments.

Details

The ProgramBlockType function returns the type ('package', 'thread', or 'data') for the current program block.

Example

The following program illustrates the PROGRAMBLOCKTYPE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
resetline;
proc ds2;
thread testthread / overwrite=yes;
   dcl char a;
   dcl varchar(100) threadtype;
   method init();
      a = 'apple';
      threadtype = programblocktype();
      put threadtype=;
  end;
endthread;

data _null_;
   dcl thread testthread t();
   dcl varchar(100) datatype;
   dcl char b;
   method init();
      b = 'banana';
      datatype = programblocktype();
      put datatype=;
  end;

   method run();
      set from t threads = 1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
78   resetline;
1    proc ds2;
2
3    thread testthread / overwrite=yes;
4      dcl char a;
5      dcl varchar(100) threadtype;
6      method init();
7    a = 'apple';
8        threadtype = programblocktype();
9    put threadtype=;
10     end;
11   endthread;
12
13   data _null_;
14   dcl thread testthread t();
15   dcl varchar(100) datatype;
16   dcl char b;
17     method init();
18       b = 'banana';
19       datatype = programblocktype();
20     put datatype=;
21     end;
22
23     method run();
24   set from t threads = 1;
25     end;
26   enddata;
27   run;
27 !      quit;
datatype=data
threadtype=thread
```

"PROGRAMBLOCKLNAME Function" on page 1027

PRXCHANGE Function

Performs a pattern-matching replacement.

Category:	Character String Matching
Restriction:	This function is superseded by the PCRX packages.
Returned data type:	CHAR
Note:	SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

Syntax

PRXCHANGE(*perl-regular-expression* | *regular-expression-id*, *times*, *source*)

Arguments

perl-regular-expression
specifies a character constant, variable, or expression with a value that is a Perl regular expression.

Data type CHAR

regular-expression-id
specifies a numeric variable with a value that is a pattern identifier that is returned from the PRXPARSE function.

Restriction If you use this argument, you must also use the PRXPARSE function.

Data type INTEGER

times
is a numeric constant, variable, or expression that specifies the number of times to search for a match and replace a matching pattern.

Data type INTEGER

Tip If the value of *times* is –1, then matching patterns continue to be replaced until the end of *source* is reached.

source
specifies a character constant, variable, or expression that you want to search.

Data type CHAR

Details

The Basics

If you use *regular-expression-id*, the PRXCHANGE function searches the *source* with the *regular-expression-id* that is returned by PRXPARSE. It returns the value in *source* with the changes that were specified by the regular expression. If there is no match, PRXCHANGE returns the unchanged value in *source*.

If you use *perl-regular-expression*, PRXCHANGE searches the *source* with the *perl-regular-expression*, and you do not need to call PRXPARSE. You can use PRXCHANGE with a *perl-regular-expression* in a WHERE clause and in PROC SQL.

Note: The following restrictions apply to PRX functions in DS2:

- Only `m`, `i`, `s`, and `x` can be used in the PRX form /.../.../ that can be preceded or followed by a single character.
- The matching mode modifiers `p`, `o`, `c`, `a`, and `l` are not supported.
- The matching mode modifier `g` is supported.

For more information about pattern matching, see "Pattern Matching Using Perl Regular Expressions (PRX) " in *SAS Functions and CALL Routines: Reference*.

Compiling a Perl Regular Expression

If *perl-regular-expression* is a constant or if it uses the /o option, then the Perl regular expression is compiled once, and each use of PRXCHANGE reuses the compiled expression. If *perl-regular-expression* is not a constant and if it does not use the /o option, then the Perl regular expression is recompiled for each call to PRXCHANGE.

Note: The compile-once behavior occurs when you use PRXCHANGE in a DS2 environment, in a WHERE clause, or in PROC SQL. For all other uses, the *perl-regular-expression* is recompiled for each call to PRXCHANGE.

Performing a Match

Perl regular expressions consist of characters and special characters that are called metacharacters. When performing a match, SAS searches a source string for a substring that matches the Perl regular expression that you specify.

To view a short list of Perl regular expression metacharacters that you can use when you build your code, see the table "Tables of Perl Regular Expression (PRX) Metacharacters" in *SAS Functions and CALL Routines: Reference*. You can find a complete list of metacharacters on the Perl website.

Comparisons

The SAS PRX* functions are provided in DS2 for compatibility with DATA step. The PCRX packages are character matching functionality that is provided by the DS2 language.

Examples

Example 1: Changing the Order of First and Last Names

The following program changes the order of first and last names.

```
/* Create a table that contains a list of names. */
proc ds2;
data names;
   dcl char(32) name;
    method run();
      name='Jones, Fred'; output;
      name='Kavich, Kate'; output;
      name='Turley, Ron'; output;
      name='Dulix, Yolanda'; output;
   end;
```

```
enddata;
run;
quit;

   /* Reverse last and first names */
proc ds2;
data ReversedNames;
   method run();
      set names;
      name=prxchange('s/(\w+), (\w+)/$2 $1/', -1, name);
   end;
enddata;
run;
quit;

proc print data=ReversedNames;
run;
```

Output 7.13 *Results from the PRXCHANGE Function*

The SAS System

Obs	name
1	Fred Jones
2	Kate Kavich
3	Ron Turley
4	Yolanda Dulix

Example 2: Changing a Matched Pattern to a Fixed Value

This program locates a pattern in a variable and replaces the variable with a predefined value. The program finds the phone numbers and replaces them with an informational message.

```
/* Create table that contains confidential information. */
proc ds2;
data a;
   dcl char(95) text;
   method run();
      text='The phone number for Ed is (801)443-9876 but not until
tonight.';
      output;
      text='He can be reached at (910)998-8762 tomorrow for testing
purposes.';
      output;
   end;
enddata;
run;
quit;
```

```
proc print data=a;
run;

   /* Locate confidential phone numbers and replace them with message
*/
   /* indicating that they have been removed.
*/
proc ds2;
data b;
   method run();
      set a;
      text=prxchange('s/\([2-9]\d\d\) ?[2-9]\d\d-\d\d\d\d/*PHONE
NUMBER REMOVED*/'
         , -1, text);
   end;
enddata;
run;
quit;

proc print data=b;
run;
```

Output 7.14 *Results Before Changing a Matched Pattern to a Fixed Value*

The SAS System

Obs	text
1	The phone number for Ed is (801)443-9876 but not until tonight.
2	He can be reached at (910)998-8762 tomorrow for testing purposes.

Output 7.15 *Results from Changing a Matched Pattern to a Fixed Value*

The SAS System

Obs	text
1	The phone number for Ed is *PHONE NUMBER REMOVED* but not until tonight.
2	He can be reached at *PHONE NUMBER REMOVED* tomorrow for testing purposes.

PRXMATCH Function

Searches for a pattern match and returns the position at which the pattern is found.

Category: Character String Matching

Restriction: This function is superseded by the PCRX packages.

Returned data type: INTEGER

Note: SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

Syntax

PRXMATCH(*perl-regular-expression*, *source*)

Arguments

perl-regular-expression
specifies a character constant, variable, or expression with a value that is a Perl regular expression.

Data type CHAR

See Tables of Perl Regular Expression (PRX) Metacharacters

source
specifies a character constant, variable, or expression that you want to search.

Data type CHAR

Details

The Basics

When you use *perl-regular-expression*, the PRXMATCH function searches *source* with the *perl-regular-expression* and returns the position at which the string begins. If there is no match, PRXMATCH returns a zero.

You can use PRXMATCH with a Perl regular expression in a WHERE clause and in PROC SQL.

Note: The following restrictions apply to PRX functions in DS2:

- Only **m**, **i**, **s**, and **x** can be used in the PRX form /.../.../ that can be preceded or followed by a single character.
- The matching mode modifiers **p**, **o**, **c**, **a**, and **l** are not supported.

For more information about pattern matching, see "Pattern Matching Using Perl Regular Expressions (PRX) " in *SAS Functions and CALL Routines: Reference*.

Compiling a Perl Regular Expression

If *perl-regular-expression* is a constant or if it uses the /o option, then the Perl regular expression is compiled once and each use of PRXMATCH reuses the compiled expression. If *perl-regular-expression* is not a constant and if it does not use the /o option, then the Perl regular expression is recompiled for each call to PRXMATCH.

Comparisons

The SAS PRX* functions are provided in DS2 for compatibility with DATA step. The PCRX packages are character matching functionality that is provided by the DS2 language.

Examples

Example 1: Finding the Position of a Substring by Using PRXPARSE

The following program searches a string for a substring, and returns its position in the string.

```
proc ds2;
 data _null_;
   dcl double patternID position;
   method init();
      /* Use PRXPARSE to compile the Perl regular expression.    */
      patternID=prxparse('/world/');
      /* Use PRXMATCH to find the position of the pattern match. */
      position=prxmatch(patternID, 'Hello world!');
      put position=;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
position=7
```

Example 2: Finding the Position of a Substring by Using a Perl Regular Expression

The following program uses a Perl regular expression to search a string (Hello world) for a substring (world) and to return the position of the substring in the string.

```
proc ds2;
data _null_;
   dcl double position;
   method run();
      position=prxmatch('/world/', 'Hello world!');
      put position=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
position=7
```

Example 3: Extracting a ZIP Code

The following program searches each row in a table for a nine-digit ZIP code, and writes those rows to the table ZipPlus4.

Note: The backslash (\) must be preceded by another backslash (\) that acts as an escape character.

```
proc ds2;
data ZipCodes (overwrite=yes);
   dcl char(16) name;
   dcl char(10) zip;
   method run();
      name='Jonathan'; zip='32532-2343'; output;
      name='Seth'; zip='85030'; output;
      name='Kim'; zip='39204'; output;
      name='Samuel'; zip='93849-3843'; output;
   end;
 enddata;
 run;
quit;

proc print data=ZipCodes;
run;

proc ds2;
data ZipPlus4 (overwrite=yes);
   method run();
```

```
      set zipcodes;
      select;
         when (prxmatch('/\d{5}-\d{4}/', zip))
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=ZipPlus4;
run;
```

Output 7.16 *Original ZIP Codes Table Output*

The SAS System

Obs	name	zip
1	Jonathan	32532-2343
2	Seth	85030
3	Kim	39204
4	Samuel	93849-3843

Output 7.17 *Nine-Digit ZIP Code Output*

The SAS System

Obs	name	zip
1	Jonathan	32532-2343
2	Samuel	93849-3843

PRXPAREN Function

Returns the last bracket match for which there is a match in a pattern.

Category:	Character String Matching
Restriction:	This function is superseded by the PCRX packages.
Requirement:	Use with the PRXPARSE function.
Returned data type:	INTEGER
Note:	SAS has adopted the International Components for Unicode (ICU). ICU enables SAS to apply regular expression matching to Unicode string data. For more information, see Regular Expressions.

Syntax

PRXPAREN(*regular-expression-id*)

Required Argument

regular-expression-id
specifies a numeric pattern identifier that is returned by the PRXPARSE function.

Data type INTEGER

Details

The PRXPAREN function is useful for finding the largest capture-buffer number that can be passed to the PRXPOSN function, or for identifying which part of a pattern matched.

For more information, see "Pattern Matching Using Perl Regular Expressions (PRX) " in *SAS Functions and CALL Routines: Reference*.

Comparisons

The SAS PRX* functions are provided in DS2 for compatibility with the DATA step. The PCRX packages are character matching functionality that is provided by the DS2 language.

Example: Using PRXPAREN to Group Quotes

The following program illustrates the PRXPAREN function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
  /* Create some source data to work with */
data all_quotes/overwrite=yes;
   dcl char(120) quote;
   method init();
      quote='A room without books is like a body without a
soul.';output;
      quote='When I have a little money, I buy books; and if I have
any left, I buy food and clothes.';output;
      quote='Books are mirrors: you only see in them what you already
have inside you.';output;
      quote='The secret of getting ahead is getting started.';output;
      quote='When I was a kid, National Geographic was my favorite
magazine.';output;
      quote='If you don''t read the newspaper, you''re uninformed. If
you read the newspaper, you''re mis-informed.';output;
      quote='To look at the newspaper is to raise a seashell to one''s
ear and to be overwhelmed by the roar of humanity.';output;
   end;
run;

/* Read source data and distribute rows to appropriate subsets */
data book_quotes
     magazine_quotes
     newspaper_quotes/overwrite=yes;
   dcl int rxID ;
   retain rxID 0;
   drop rxID;
   method init();
      rxID=prxparse('/(book)|(magazine)|(newspaper)/i');
   end;
   method run();
      dcl int rc pattern;
      set all_quotes;
      /* Use PRXMATCH to search for a match and return a position, if
found.  */
      rc=prxmatch(rxID,quote);
      if not rc then do;
         /* Message for quotes that did not match any pattern */
         put 'This quote didn''t match:';
```

```
            put quote=;
         end;
         else do;
            /* When a match is found, identify which pattern matched. */
            pattern=prxparen(rxID);
            /* Output the quote to the appropriate subset:
               1=book, 2=magazine, 3=newspaper */
            if pattern=1 then output book_quotes;
            else if pattern=2 then output magazine_quotes;
            else if pattern=3  then output newspaper_quotes;
         end;
      end;
   enddata;
   run;
   quit;

   /* Print the input and output data sets. */
   title "All Quotes";
   proc print data=all_quotes; run;
   title "Book Quotes";
   proc print data=book_quotes; run;
   title "Magazine Quotes";
   proc print data=magazine_quotes; run;
   title "Newspaper Quotes";
   proc print data=newspaper_quotes; run;
   title;
```

Here are the outputs from the example:

All Quotes

Obs	quote
1	A room without books is like a body without a soul.
2	When I have a little money, I buy books; and if I have any left, I buy food and clothes.
3	Books are mirrors: you only see in them what you already have inside you.
4	The secret of getting ahead is getting started.
5	When I was a kid, National Geographic was my favorite magazine.
6	If you don't read the newspaper, you're uninformed. If you read the newspaper, you're mis-informed.
7	To look at the newspaper is to raise a seashell to one's ear and to be overwhelmed by the roar of humanity.

Book Quotes

Obs	quote
1	A room without books is like a body without a soul.
2	When I have a little money, I buy books; and if I have any left, I buy food and clothes.
3	Books are mirrors: you only see in them what you already have inside you.

Magazine Quotes

Obs	quote
1	When I was a kid, National Geographic was my favorite magazine.

Newspaper Quotes

Obs	quote
1	If you don't read the newspaper, you're uninformed. If you read the newspaper, you're mis-informed.
2	To look at the newspaper is to raise a seashell to one's ear and to be overwhelmed by the roar of humanity.

PRXPARSE Function

Compiles a Perl regular expression (PRX) that can be used for pattern matching of a character value.

Category: Character String Matching

Restrictions: This function is superseded by the PCRX packages.
Use with other Perl regular expressions.

Returned data type: INTEGER

Note: SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

Syntax

regular-expression-id=**PRXPARSE**(*perl-regular-expression*)

Arguments

regular-expression-id
is a numeric pattern identifier that is returned by the PRXPARSE function.

Data type INTEGER

perl-regular-expression
specifies a character, constant, variable, or expression with a value that is a Perl regular expression.

Data type CHAR

Details

The Basics

The PRXPARSE function returns a pattern identifier number that is used by other Perl functions to match patterns. If an error occurs in parsing the regular expression, SAS returns a missing value.

PRXPARSE uses metacharacters in constructing a Perl regular expression. To view a table of common metacharacters, see "Tables of Perl Regular Expression (PRX) Metacharacters" in *SAS Functions and CALL Routines: Reference*.

Note: The following restrictions apply to PRX functions in DS2:

- Only **m**, **i**, **s**, and **x** can be used in the PRX form /.../.../ that can be preceded or followed by a single character.
- The matching mode modifiers **p**, **o**, **c**, **a**, and **l** are not supported.

For more information about pattern matching, see "Pattern Matching Using Perl Regular Expressions (PRX)" in *SAS Functions and CALL Routines: Reference*.

Compiling a Perl Regular Expression

If *perl-regular-expression* is a constant, the Perl regular expression is compiled only once. Successive calls to PRXPARSE do not cause a recompile, but return the *regular-expression-id* for the regular expression that was already compiled. This behavior simplifies the code because you do not need to use an initialization block (IF _N_ =1) to initialize Perl regular expressions.

Comparisons

The SAS PRX* functions are provided in DS2 for compatibility with DATA step. The PCRX packages are character matching functionality that is provided by the DS2 language.

Examples

Example 1: Compiling a Perl Regular Expression

The following program uses PRXPARSE to compile the Perl regular expression.

```
proc ds2;
 data _null_;
   dcl double patternID position;
   method init();
      /* Use PRXPARSE to compile the Perl regular expression.    */
      patternID=prxparse('/world/');
      /* Use PRXMATCH to find the position of the pattern match. */
      position=prxmatch(patternID, 'Hello world!');
      put position=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
position=7
```

Example 2: Using PRXPARSE to Reverse First and Last Names

The following program uses PRXPARSE to reverse the first and last names.

```
proc ds2;
 data _null_;
   dcl double patternID position;
   dcl char(32) names[4];
   dcl int i;
   method init();
       names := ('Jones, Fred   '
                 'Kavich, Kate  '
                 'Turley, Ron   '
                 'Dulix, Yolanda');

       /* Reverse last and first names */
       do i = 1 to dim(names);
          names[i]=prxchange('s/(\w+), (\w+)/$2 $1/', -1, names[i]);
          put names[i];
       end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Fred Jones
Kate Kavich
Ron Turley
Yolanda Dulix
```

PRXPOSN Function

Returns a character string that contains the value for a capture buffer.

Category: Character String Matching

Restriction: This function is superseded by the PCRX packages.

Returned data type: CHAR

Note: SAS has adopted the International Components for Unicode (ICU) to implement regular expression matching to Unicode string data. For more information, see Regular Expressions.

Syntax

PRXPOSN(*regular-expression-id*, *capture-buffer*, *source*)

Arguments

regular-expression-id
specifies a numeric variable with a value that is a pattern identifier that is returned by the PRXPARSE function.

Data type INTEGER

capture-buffer
is a numeric constant, variable, or expression that identifies the capture buffer for which to retrieve a value:

- If the value of *capture-buffer* is zero, PRXPOSN returns the entire match.
- If the value of *capture-buffer* is between 1 and the number of open parentheses in the regular expression, then PRXPOSN returns the value for that capture buffer.
- If the value of *capture-buffer* is greater than the number of open parentheses, then PRXPOSN returns a missing value.

Data type INTEGER

source
specifies the text from which to extract capture buffers.

Data type CHAR

Details

The PRXPOSN function uses the results of PRXMATCH or PRXCHANGE to return a capture buffer. A match must be found by one of these functions for PRXPOSN to return meaningful information.

Note: The following restrictions apply to PRX functions in DS2:

- Only **m**, **i**, **s**, and **x** can be used in the PRX form /.../.../ that can be preceded or followed by a single character.
- The matching mode modifiers **p**, **o**, **c**, **a**, and **l** are not supported.

For more information about pattern matching, see "Pattern Matching Using Perl Regular Expressions (PRX) " in *SAS Functions and CALL Routines: Reference*.

Comparisons

The SAS PRX* functions are provided in DS2 for compatibility with DATA step. The PCRX packages are character matching functionality that is provided by the DS2 language.

Examples

Example 1: Extracting First and Last Names

The following program uses PRXPOSN to extract first and last names from a table.

```
proc ds2;
data ReversedNames;
   dcl char(32) name;
   method init();
      name='Jones, Fred'; output;
      name='Kavich, Kate'; output;
      name='Turley, Ron'; output;
      name='Dulix, Yolanda'; output;
   end;
enddata;
run;
quit;

proc ds2;
data FirstLastNames (overwrite=yes);
   dcl char(16) first last;
   dcl double re;
   keep first last;
   retain re;

   method init();
```

```
      dcl varchar(32) expression;
      expression = '/(\w+), (\w+)/';
      re=prxparse(expression);
      if missing( re ) then do;
         put 'ERROR: Invalid expression ' expression;
         stop;
      end;
   end;

   method run();
      set ReversedNames;
      if prxmatch(re, name) then
         do;
            last=prxposn(re, 1, name);
            first=prxposn(re, 2, name);
         end;
   end;
enddata;
run;
quit;

proc print data=FirstLastNames;
run;
```

Output 7.18 *Output from PRXPOSN: First and Last Names*

The SAS System

Obs	first	last
1	Fred	Jones
2	Kate	Kavich
3	Ron	Turley
4	Yolanda	Dulix

Example 2: Extracting Names When Some Names Are Invalid

The following program creates a table that contains a list of names. Rows that have only a first name or only a last name are invalid. PRXPOSN extracts the valid names from the table, and writes the names to the table NEW.

```
proc ds2;
data old (overwrite=yes);
   dcl char(60) name;
   method init();
      name='Judith S Reaveley'; output;
      name='Ralph F. Morgan'; output;
      name='Jess Ennis'; output;
      name='Carol Echols'; output;
      name='Kelly Hansen Huff'; output;
      name='Judith'; output;
      name='Nick'; output;
      name='Jones'; output;
```

```
   end;
enddata;
run;
quit;

proc ds2;
data new (overwrite=yes);
   dcl char(40) first middle last;
   keep first middle last;

   method run();
      re=prxparse('/(\S+)\s+([^\s]+\s+)?(\S+)/i');
      set old;
      if prxmatch(re, name) then
         do;
            first=prxposn(re, 1, name);
            middle=prxposn(re, 2, name);
            last=prxposn(re, 3, name);
            output;
         end;
   end;
enddata;
run;
quit;

proc print data=new;
run;
```

Output 7.19 *Output of Valid Names*

The SAS System

Obs	first	middle	last
1	Judith	S	Reaveley
2	Ralph	F.	Morgan
3	Jess		Ennis
4	Carol		Echols
5	Kelly	Hansen	Huff

PUT Function

Returns a value using a specified format.

Category: Special

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

PUT(*expression*, *format*)

Required Arguments

expression
specifies any valid expression.

Data type: DOUBLE, DATE, TIME, TIMESTAMP, CHAR, NCHAR, NVARCHAR, VARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

format.
specifies either a DS2 format or a user-defined format that you want applied to *expression*.

To override the default alignment, you can add an alignment specification to a format:

–L
left aligns the value

–C
centers the value

–R
right aligns the value

Details

If a value is not specified for the format width or decimal specification, DS2 uses the default values for that format. Note that when using input-width aware formats, the width, decimal specification, or both is calculated from the input field width. For more information, see "Write Formatted Data in DS2" on page 65.

If *expression* is not a valid data type for the format type (either numeric or character), DS2 converts *expression* to a valid data type for *format.*, with these exceptions:

- date and time expressions are converted to a SAS date, time, or datetime DOUBLE value for numeric formats, and converted to NCHAR for character string formats
- when the format is a binary character format such as $BINARY, $HEX or $OCTAL, expressions with a data type of DOUBLE are converted to NCHAR
- an error is issued when an expression with a data type of VARBINARY is used with a numeric format that does not produce a data type of VARBINARY

When DS2 converts an expression's data type in an assignment statement, the result is left-aligned.

You can use the PUT function to convert a numeric value to a character value and to convert a date, time, or timestamp value to a SAS date/time value.

Comparisons

The PUT function and the PUT statement have similar behavior. However, the PUT statement directs its results to the SAS log whereas the PUT function returns an NCHAR value containing the result of formatting its argument.

Examples

Example 1: Formatting Values with PUT

The following programs illustrate the PUT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char x;
   method run();
      x=put(17180, date7.);
      put x;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
14JAN07
```

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=put('AB', $binary.);
      put x;
      end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
100000101000010
```

```
proc ds2;
data test(overwrite=yes);
   dcl double a x;
   method run();
      a=35436745.3354;
      x=put(a, comma20.4);
      put x;
   end;
enddata;
run;quit;
```

SAS writes the following output to the log:

```
   35,436,745.3354
```

```
proc ds2;
data test(overwrite=yes);
   dcl double a x;
   method run();
      a=35436745.3354;
      x=put(a, comma20.4 -L);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
35,436,745.3354
```

Example 2: Using a PROC FORMAT Format

The following program creates a user-defined format and uses that format with the PUT function.

```
proc format;
value abc 1="Yes" 2="No";
run;

proc ds2;
data test (overwrite=yes);
   dcl double d e;
   dcl char(3) x y;
   method run();
      d=1;
      x=put(d, abc.);
      put x=;
      e=2;
      y=put(e, abc.);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=Yes
y=No
```

- “INPUTN Function” on page 721

PUTC Function

Enables you to specify a character format at run time.

Category:	Special
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

PUTC(*value*, *format-specification* [, *w*])

Required Arguments

value
specifies a character value to be formatted.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

format-specification
is a character format that you want to apply to *value*.

Here are valid format forms:

- *format-name*
- *format-name.* (the format name ends with a period)
- *format-namew*.

Except for *format-name*, you can use –L, –R, and –C in *format-specification* to left-align, right-align, and center your output. For example, you can use `'upcase.-c'` as the value for the second argument, *format-specification*.

Optional Argument

w
is a numeric constant, variable, or expression that specifies a width to apply to the format.

Interaction If you specify a width here, it overrides any width specification in the format.

Details

If the PUTC function returns a value to a variable that has not yet been assigned a length, then the variable length is determined by the length of the first argument.

Comparisons

The PUTN function enables you to specify a numeric format at run time.

The PUT function is faster than PUTC because PUT enables you to specify a format at compile time rather than at run time.

The PUT function uses DS2 character semantics to apply the format width. That is, the PUT function interprets *w* as the number of characters to include in the formatted string. The PUTC function uses SAS byte semantics.

Note: When used with a multi-byte character set, PUTC can truncate values.

Examples

Example 1: Working with the PUTC Function

The PROC FORMAT step creates a format, TYPEFMT., that formats the variable values 1, 2, and 3 with the name of one of the three other formats that this step creates. These three formats output responses of "positive," "negative," and "neutral" as different words, depending on the type of question. After PROC FORMAT creates the formats, the DATA step creates a SAS data set from raw data that consists of a number identifying the type of question and a response. After reading a record, the DATA step uses the value of TYPE to create a variable, RESPFMT. This variable contains the value of the appropriate format for the current type of question. The DATA step also creates another variable, WORD, whose value is the appropriate word for a response. The PUTC function assigns the value of WORD based on the type of question and the appropriate format.

```
proc format;
   value typefmt 1='$groupx'
                 2='$groupy'
                 3='$groupz';
   value $groupx 'positive'='agree'
                 'negative'='disagree'
                 'neutral'='notsure ';
   value $groupy 'positive'='accept'
                 'negative'='reject'
                 'neutral'='possible';
   value $groupz 'positive'='pass    '
                 'negative'='fail'
                 'neutral'='retest';
run;

proc ds2;
data input_data (overwrite=yes);
dcl double type;
dcl char(8) response;
method init();
  do type = 1 to 3;
    do response = 'positive', 'negative', 'neutral';
     output;     end;
    end;
 end;
enddata;
run;

data answers (overwrite=yes);
   method run();
    set input_data;
    respfmt=put(type, typefmt.);
    word=putc(response, respfmt);
   end;
enddata;
run;
quit;

proc print data=answers;
```

```
   title 'Using the Third Argument as a Number or Cycle';
run;
```

Output 7.20 *Output from Using the PUTC Function*

Using the Third Argument as a Number or Cycle

Obs	type	response	respfmt	word
1	1	positive	$groupx	agree
2	1	negative	$groupx	disagree
3	1	neutral	$groupx	notsure
4	2	positive	$groupy	accept
5	2	negative	$groupy	reject
6	2	neutral	$groupy	possible
7	3	positive	$groupz	pass
8	3	negative	$groupz	fail
9	3	neutral	$groupz	retest

The value of the variable WORD is `agree` for the first observation. The value of the variable WORD is `retest` for the last observation.

Example 2: Aligning Character Values

This example shows how to use a format and an alignment character to align the value of A.

```
proc ds2;
data _null_;
   dcl char(20) a y;
   method init();
   a='experiment';
   y=putc(a,'upcase.-r',20);
   put '*' y $char20. '*';
   put '*' a $upcase20. '*';
   end;
  enddata;
run;
quit;
```

```
*          EXPERIMENT*
*EXPERIMENT          *
```

PUTN Function

Enables you to specify a numeric format at run time.

Category: Special

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

PUTN(*value*, *format-specification* [, *w* [, *d*]])

Required Arguments

value
specifies a numeric value to be formatted.

Data type BIGINT, DECIMAL, DOUBLE, FLOAT, SMALLINT, TINYINT

format-specification
is the numeric format that you want to apply to *value*.

Here are valid format forms:

- *format-name*
- *format-name.* (the format name ends with a period)
- *format-namew*.
- *format-namew.d*

Except for *format-name*, you can use –L, –R, and –C in *format-specification* to left-align, right-align, and center your output. For example, you can use `'weekdate.-c'` as the value for the second argument, *format-specification*.

Optional Arguments

w
is a numeric constant, variable, or expression that specifies a width to apply to the format.

Interaction If you specify a width here, it overrides any width specification in the format.

d

is a numeric constant, variable, or expression that specifies the number of decimal places to use.

Interaction If you specify a number here, it overrides any decimal-place specification in the format.

Details

If the PUTN function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 200 bytes.

Comparisons

The PUTC function enables you to specify a character format at run time.

The PUT function is faster than PUTN because PUT applies the format at compile time rather than at run time.

The PUT function uses DS2 character semantics to apply the format width. That is, the PUT function interprets *w* as the number of characters to include in the formatted string. The PUTN function uses SAS byte semantics.

Note: When used with a multi-byte character set, PUTN can truncate values.

Examples

Example 1: Working with Dates and Formats in the PUTN Function

The PROC FORMAT step creates a format, WRITFMT., that formats the variable values 1 and 2 with the name of a SAS date format. The DATA step creates a SAS data set from raw data that consists of a number and a key. After reading a record, the DATA step uses the value of KEY to create a variable, DATEFMT, that contains the value of the appropriate date format. The DATA step also creates a new variable, DATE, whose value is the formatted value of the date. PUTN assigns the value of DATE based on the value of NUMBER and the appropriate format.

```
proc format;
   value writfmt 1='date9.'
                 2='mmddyy10.';
run;

proc ds2;
data input_data (overwrite=yes);
dcl double number key;
```

```
dcl char(15) datefmt newdate;
method init();
number = 15756;
key = 1;
output;
number = 14552;
key = 2;
output;
end;
enddata;
run;

data dates (overwrite=yes);
method run();
set input_data;
datefmt=put(key, writfmt.);
newdate=putn(number, datefmt);
end;
enddata;
run;
quit;

proc print data=dates;
   title 'Working with Dates and Formats';
run;
```

Output 7.21 *Output from Using the PUTN Function*

Working with Dates and Formats

Obs	number	key	datefmt	newdate
1	15756	1	date9.	20FEB2003
2	14552	2	mmddyy10.	11/04/1999

Example 2: Aligning Output from the PUTN Function

This example shows how to use a format and an alignment character to left-align a value.

```
proc ds2;
data _null_;
   dcl char(30) y;
   method init();
   y=putn(today(),'weekdate.-l',30);
   put '*' y $char30. '*';
   end;
 enddata;
run;
```

Example Code 7.1 *Alignment Results*

```
*Monday, November 19, 2012     *
```

PVP Function

Returns the present value for a periodic cash flow stream (such as a bond), with repayment of principal at maturity.

Category: Financial

Returned data type: DOUBLE

Syntax

PVP(*A*, *c*, *n*, *K*, k_0, *y*)

Required Arguments

A

specifies the par value.

Ranges $A > 0$

A > 0

Data type DOUBLE

c

specifies the nominal per-year coupon rate, expressed as a fraction.

Ranges $0 \leq c < 1$

0 ≤ *c* < 1

Data type DOUBLE

n

specifies the number of coupons per year.

Ranges $n > 0$

$n > 0$

Data type DOUBLE

K

specifies the number of remaining coupons.

Ranges $K > 0$

$K > 0$

Data type DOUBLE

k_0

specifies the time from the present date to the first coupon date, expressed in terms of the number of years.

Ranges $0 < k_0 \leq \frac{1}{n}$

$0 < k_0 \leq 1/n$

Data type DOUBLE

y

specifies the nominal per-year yield-to-maturity, expressed as a fraction.

Ranges $y > 0$

$y > 0$

Data type DOUBLE

Details

The PVP function is based on the following relationship:

$$P = \sum_{k=1}^{K} \frac{c(k)}{\left(1 + \frac{y}{n}\right)^{t_k}}$$

The following relationships apply to the preceding equation:

- $t_k = nk_0 + k - 1$
- $c(k) = \frac{c}{n}A \quad for\ k = 1, \ldots, K-1$
- $c(K) = \left(1 + \frac{c}{n}\right)A$

Example

The following program illustrates the PVP function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double p;
   method run();
      p=pvp(1000,.01,4,14,.33/2,.10);
      put p;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
743.167613519067
```

QTR Function

Returns the quarter of the year from a SAS date value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

QTR(*date*)

Required Argument

date
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The QTR function returns a value of 1, 2, 3, or 4 from a SAS date value to indicate the quarter of the year in which a date value falls.

For more information about how DS2 handles date and time values, see "DS2 Expressions" in *SAS DS2 Programmer's Guide*.

Example

The following program illustrates the QTR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a b c;
   method run();
      a=17180;
      b=put(a, date7.);
      c=qtr(a);
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1
```

QUANTILE Function

Returns the quantile from a distribution when you specify the left probability (CDF).

Category:	Quantile
Returned data type:	DOUBLE

See: "CDF Function" on page 362

Syntax

QUANTILE(*'distribution'*, *probability*, *parameter-1, ..., parameter-k*)

Required Arguments

distribution
is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the QUANTILE distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'

Distribution	Argument
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL'|'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD'|'IGAUSS'
Weibull	'WEIBULL'

Note: Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

probability
is a numeric constant, variable, or expression that specifies the value of a random variable.

parameter-1, ..., parameter-k
are optional *shape*, *location*, or *scale* parameters appropriate for the specific distribution.

Details

The QUANTILE function computes the quantile from the specified continuous or discrete distribution, based on the probability value that is provided. For more information, see the individual distributions noted in the table above.

The Conway-Maxwell-Poisson distribution for the QUANTILE function returns the counts value *y* that is the largest whole number whose CDF value is less than or equal to *p*. The syntax for the Conway-Maxwell-Poisson distribution in the QUANTILE function has the following form:

QUANTILE('CONMAXPOI',*p*,*λ*,*v*)

p
is a real number between 0 and 1, inclusively.

λ
is similar to the mean, as in the Poisson distribution.

v
is a dispersion parameter.

For more information, see "Conway-Maxwell-Poisson" distribution in the PDF function on page 941.

Example

The following program illustrates the QUANTILE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double a b c d e f g h i j k l m n o p q r x t;
   method init();
      a=quantile('BERN', .75, .25);
      b=quantile('BETA', 0.1,3,4);
      c=quantile('BINOM',.4, .5, 10);
      d=quantile('CAUCHY', .85);
      e=quantile('CHISQ', .6,11);
      f=quantile('CONMAXPOI',0.2,2.3,.4);
      g=quantile('EXPO', .6);
      h=quantile('F',.8,2,3);
      i=quantile('GAMMA', .4,3);
      j=quantile('GENPOI', .9, 1, .7);
      k=quantile('HYPER', .5, 200, 50, 10);
      l=quantile('LAPLACE', .8);
      m=quantile('LOGISTIC', .7);
      n=quantile('LOGNORMAL', .5);
      o=quantile('NEGB', .5, .5, 2);
      p=quantile('NORMAL', .975);
      q=quantile('NORMALMIX',0.5, 1, 0.2, 1.1,0.1);
      r=quantile('PARETO', .01,1);
      s=quantile('POISSON', .9, 1);
      t=quantile('T', .8, 5);
      u=quantile('TWEEDIE', .8, 5);
      v=quantile('UNIFORM', 0.25);
      w=quantile('WALD', .6, 2);
      x=quantile('WEIBULL', .6, 2);
      put a=;
      put b=;
      put c=;
      put c=;
      put e=;
      put f=;
      put g=;
      put h=;
      put i=;
      put j=;
```

```
        put k=;
        put l=;
        put m=;
        put n=;
        put o=;
        put p=;
        put q=;
        put r=;
        put s=;
        put t=;
        put u=;
        put v=;
        put w=;
        put x=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=0
b=0.2009088788569
c=5
d=1.96261050550515
e=11.5298338409688
f=5

QUOTE Function

Adds double quotation marks to a character value.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

QUOTE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The QUOTE function adds double quotation marks, the default character, to a character value. If double quotation marks are found within the argument, they are doubled in the output.

The length of the receiving variable must be long enough to contain the argument (including trailing blanks), leading and trailing quotation marks, and any embedded quotation marks that are doubled. For example, if the argument is ABC followed by three trailing blanks, then the receiving variable must have a length of at least eight to hold "ABC###". (The character # represents a blank space.) If the receiving field is not long enough, the QUOTE function returns a blank string, and writes an invalid argument note to the SAS log.

A string of characters enclosed in double quotation marks is a DS2 identifier and not a character constant. The double quotation marks become part of the identifier. Quoted identifiers cannot be used to create column names in an output table.

Example

The following program illustrates the QUOTE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl varchar(6) a b c d;
   dcl varchar(30) e f;
   method run();
      a='A"B';
      b=quote(a);
      put b;
      c='A''B';
      d=quote(c);
      put d;
      e='Paul''s Catering Service     ';
      f=quote(trim(e));
      put f;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
"A""B"
"A'B"
"Paul's Catering Service"
```

RANBIN Function

Returns a random variate from a binomial distribution.

Note: This function is no longer supported. Use the RAND('BINOMIAL') function on page 1071 instead.

RANCAU Function

Returns a random variate from a Cauchy distribution.

Note: This function is no longer supported. Use the RAND('CAUCHY') function on page 1071 instead.

RAND Function

Generates random numbers from a distribution that you specify.

Category: Random Number

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

RAND('*distribution*', *parameter-1, ...parameter-k*)

Required Arguments

distribution
is a character constant, variable, or expression that identifies the distribution. Valid distributions are as follows:

Distribution	Function Call	Parameter Values
Bernoulli	`RAND('BERNoulli', prob)`	where (0 <= prob <= 1)
Beta	`RAND('BETA', alpha, beta)`	where (0.01 <= alpha <= 1.5e6) and (0.20 <= beta <= 1.5e6)
Binomial	`RAND('BINOmial', prob, trials)`	where (0 <= prob <= 1) and (0 <= trials)
Cauchy	`RAND('CAUChy')`	
Chi-Square(d)	`RAND('CHISquare', df)`	where 0.03 <= df <= 4e9
Erlang	`RAND('ERLAng', alpha)`	where 1 <= alpha <= 2e9
Exponential	`RAND('EXPOnential', scale )`	where 0 <= scale <= 1e300
Extreme Value	`RAND('EXTReme')`	default m = 0, scale = 1, shape = 0
	`RAND('EXTReme', mu)`	where –1e300 <= mu <= 1e300

Distribution	Function Call	Parameter Values
	`RAND('EXTReme', mu, scale)`	where scale > 0
	`RAND('EXTReme', mu, scale, shape)`	where (scale > 0) and (–0.5 <= shape <= 5)
F	`RAND('F', numdf, dendf)`	where (0.025 <= numdf <= 1e7) and (0.1 <= dendf <= 2e9)
Gamma	`RAND('GAMMa', alpha)`	where 0.015 <= alpha <= 2e9, default scale = 1
	`RAND('GAMMa', alpha, scale)`	where (1e–80 <= scale <= 1e295) or (scale = 0)
Geometric	`RAND('GEOMetric', prob)`	where 0 < prob <= 1
Gompertz	`RAND('GOMPertz')`	default shape = 1, scale = 1
	`RAND('GOMPertz' shape )`	where shape >= 1e–300
	`RAND('GOMPertz' shape , scale )`	where (shape >= 1e–300) and (scale >= 0)
Gumbel	`RAND('GUMBel')`	default mu = 0, scale = 1
	`RAND('GUMBel', mu)`	where –1e300 <= mu <= 1e300
	`RAND('GUMBel', mu, scale)`	where (-1e300 <= mu <= 1e300) and (scale >= 0)
Hypergeometric	`RAND('HYPErgeometric', pop_size, cat_size, samp_size)`	where 1 <= pop_size <= 9e15 and 0 <= cat_size <= pop_size and 1 <= samp_size <= pop_size
Uniform Integer	`RAND('INTEger', int)`	where –2147483648 <= int <= 2147483647
Laplace	`RAND('LAPLace')`	default mu = 0, scale = 1
	`RAND('LAPLace', mu)`	where –1e300 <= mu <= 1e300
	`RAND('LAPLace', mu, scale)`	where (–1e300 <= mu <= 1e300) and (scale >= 0)
Logistic	`RAND('LOGIstic')`	default mu = 0, scale = 1
	`RAND('LOGIstic', mu)`	where –1e300 <= mu <= 1e300
	`RAND('LOGIstic', mu, scale)`	where (–1e300 <= mu <= 1e300) and (scale >= 0)

Distribution	Function Call	Parameter Values
Log-normal	`RAND('LOGNormal')`	default mu = 0, sigma = 1
	`RAND('LOGNormal', mu)`	where ABS(mu) <= 702
	`RAND('LOGNormal', mu, sigma)`	where (ABS(mu) + 7*sigma <= 709) and ((sigma >= max(1, ABS(mu)) * 1e–13) or (sigma = 0))
Negative Binomial	`RAND('NEGBinomial', prob, n)`	where (0 < prob <= 1) and (n >= 1)
Normal or Gaussian	`RAND('NORMal')`	default mu = 0, sigma = 1
	`RAND('NORMal', mu)`	where ABS(mu) <= 1e14
	`RAND('NORMal', mu, sigma)`	where (ABS(mu) <= 1e14*sigma) or (sigma = 0)
Pareto	`RAND('PAREto')`	default shape = 1, scale = 1
	`RAND('PAREto', shape)`	where shape .04 <= xi <= 1e10
	`RAND('PAREto', shape, scale)`	where (shape .04 <= xi <= 1e10) and (0 <= scale <=1e100)
Poisson	`RAND('POISson', mean)`	where 0 <= mean <= 1e300
Shifted Gompertz	`RAND('SHGOmpertz')`	default shape = 1, inverse_scale = 1
	`RAND('SHGOmpertz', shape)`	where shape >= 1e–300
	`RAND('SHGOmpertz', shape, inverse_scale)`	where (shape >= 1e–300) and (inverse_scale >= 1e-300)
T	`RAND('T', df)`	where df >= 0.05
Tabled	`RAND('TABLe', p_1, ..., p_n)`	where (0 <= pi <= 1) and (p_1 + ... + p_n <= 1)
Triangular	`RAND('TRIAngular', height)`	where 0 <= height <= 1
Uniform	`RAND('UNIForm')`	default a = 1, b = 0
	`RAND('UNIForm', a)`	uniform on (min(a,0) max(a,0))
	`RAND('UNIForm', a, b)`	uniform on (min(a,b) max(a,b))
Wald (Inverse Gaussian)	`RAND('WALD', shape)`	where 1e–18 <= shape <= 1e17, default mu = 1

Distribution	Function Call	Parameter Values
	`RAND('WALD', shape, mu)`	where (shape >= 1e–18) and (mu >= 1e–10) and (1e–21 <= shape/mu <= 1e17)
Weibull	`RAND('WEIBull', shape)`	where 0.02 <= shape <= 1e13, default scale = 1
	`RAND('WEIBull', shape, scale)`	where (0.02 <= shape <= 1e13) and (1e–100 <= scale <= 1e20)

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note Except for T and F, you can minimally identify any distribution by its first four characters.

parameter-1, ...parameter-k
are optional numeric constants, variables, or expressions that specify the values of *shape*, *location*, or *scale* parameters that are appropriate for the specific distribution.

See "Details" on page 1074

Details

Generating Random Numbers

The RAND function generates random numbers from various continuous and discrete distributions. Wherever possible, the simplest form of the distribution is used.

The RAND function uses the Mersenne-Twister random number generator (RNG) that was developed by Matsumoto and Nishimura (1998). Other random number generators can be specified by the STREAMINIT function.

The RAND function is started with a single seed. However, the state of the process cannot be captured by a single seed. You cannot stop and restart the generator from its stopping point.

For the default 32-bit Mersenne Twister, if the initial seed is exactly divisible by 8192, the RAND function uses the 2002 initialization algorithm (Matsumoto and Nishimura, 2002). Otherwise, RAND uses the 1998 initialization algorithm for compatibility with previous releases.

Reproducing a Random Number Stream

If you want to create reproducible streams of random numbers, then use the STREAMINIT function before any invocation of the RAND function to specify a seed value for random number generation. Use the STREAMINIT function once per

data program.For more information, see the example in "STREAMINIT Function" on page 1173.

When called from a DS2 program, the following FCMP functions do not recognize seed values that are set in the DS2 program.

COMPCOST
COMPGED
RAND
STREAMINIT

In a DATA step, all random numbers from RAND are drawn from the same stream by default, but you can create multiple independent streams by using the CALL STREAM routine.

In PROC DS2, random numbers from RAND that are called inside an FCMP package come from a separate stream. To get reproducible random numbers, use the CALL STREAMINIT routine inside each FCMP function that calls RAND. To get independent streams, also use the CALL STREAM routine inside each FCMP function that calls RAND. If you do so, the results from DS2 are consistent with a DATA step. For an example, see "Considerations and Limitations When Using the FCMP Package" in *SAS DS2 Programmer's Guide*.

Duplicate Values

The RNG algorithms used by the RAND function have extremely long periods, but this does not imply that large random samples are devoid of duplicate values. With the default 32-bit Mersenne Twister algorithm, the RAND function returns at most 2^{32} distinct values. In a random uniform sample of size 10^5, the chance of drawing at least one duplicate is greater than 50%. The expected number of duplicates in a random uniform sample of size M is approximately $M^2/2^{33}$ when M is much less than 2^{32}. For example, you should expect about 115 duplicates in a random uniform sample of size $M=10^6$. These results are consequences of the famous "birthday matching problem" in probability theory.

For a 64-bit RNG, RAND('UNIFORM') can return at least $2^{53} - 1$ distinct values. For a sample size of 10^8, the chance of drawing at least one duplicate is greater than 50%. For a sample size of 10^9, the expected number of duplicates is about 55.55.

Extreme Parameter Values

Pseudorandom numbers are generated by using numerical algorithms that transform uniform random variates. For some distributions, very small or very large parameter values can result in pseudorandom variates that do not adequately follow the theoretical distribution. For other distributions, extreme parameter values can lead to numerical underflow or overflow during a computation. The RAND function attempts to identify regions of parameter space that might lead to these problems.

If the RAND function determines that extreme parameters might lead to invalid pseudorandom variates, it returns a missing value and writes a warning message to the SAS log. For example, a small value of the parameter in the chi-square distribution (such as d=0.01) can produce the following warning message and cause the RAND function to return a missing value:

```
WARNING: In the function call, RAND('CHISQUARE', 0.01), there is a risk
         of underflow that would cause the distribution of the random
         numbers to be wrong. It is recommended that you use
         RAND('CHISQUARE', df), where 0.03 <= df <= 4e9.
```

The RAND function generates random numbers (despite the possibility of a poor distribution). To suppress the warning and cause, append a question mark to the end of the name of the distribution that is specified in the first argument. An example is RAND('CHISQUARE?',.01).

Bernoulli Distribution

x=**RAND**('BERNOULLI', *p*)

Arguments

x

is an observation from the Bernoulli distribution with the following probability density function:

$$f(x) = \begin{cases} 1 & p = 0, x = 0 \\ p^x(1-p)^{1-x} & 0 < p < 1, x = 0, 1 \\ 1 & p = 1, x = 1 \end{cases}$$

Range *x*=0, 1

p

is a numeric probability of success.

Range $0 \le p \le 1$

Beta Distribution

x = **RAND**('BETA', *a*, *b*)

Arguments

x

is an observation from the Beta distribution with the following probability density function:

$$f(x) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1-x)^{b-1}$$

Range $0 < x < 1$

a

is a numeric shape parameter.

Range $a > 0$

b

is a numeric shape parameter.

Range $b > 0$

Binomial Distribution

x = **RAND**('BINOMIAL', p, n)

Arguments

x

is an observation that is a whole number from the Binomial distribution with the following probability density function:

$$f(x) = \begin{cases} 1 & p = 0, x = 0 \\ \binom{n}{x} p^x (1-p)^{n-x} & 0 < p < 1, x = 0, \ldots, n \\ 1 & p = 1, x = n \end{cases}$$

Range $x = 0, 1, \ldots, n$

p

is a numeric probability of success.

Range $0 \le p \le 1$

n

is a parameter that counts the number of independent Bernoulli trials. This argument must be a whole number.

Range $n = 1, 2, \ldots$

Cauchy Distribution

x = **RAND**('CAUCHY')

Arguments

x

is an observation from the Cauchy distribution with the following probability density function:

$$f(x) = \frac{1}{\pi\left(1 + x^2\right)}$$

Range $-\infty < x < \infty$

Chi-Square Distribution

x = **RAND**('CHISQUARE', df)

Arguments

x

is an observation from the Chi-Square distribution with the following probability density function:

$$f(x) = \frac{2^{-df/2}}{\Gamma\left(\frac{df}{2}\right)} x^{df/2-1} e^{-x/2}$$

Range $x > 0$

df

is a numeric degrees of freedom parameter.

Range $df > 0$

Erlang Distribution

x = **RAND**('ERLANG', *a*)

Arguments

x

is an observation from the Erlang distribution with the following probability density function:

$$f(x) = \frac{1}{\Gamma(a)} x^{a-1} e^{-x}$$

Range $x > 0$

a

is a numeric shape parameter. This argument must be a whole number.

Range $a = 1, 2, \ldots$

Exponential Distribution

x = **RAND**('EXPONENTIAL' ,[σ])

Arguments

x

is an observation from the Exponential distribution with the following probability density function:

$$f(x) = e^{-x}$$

Range $x > 0$

σ

is a scale parameter.

Default 1

Range σ > 0

Extreme Value Distribution

x=**RAND**('EXTRVALUE', [*μ*, *σ*, *ξ*])

Arguments

x

is an observation from the extreme value distribution, which has the following cumulative probability distribution:

$$F(x) = \exp(t(x))$$
$$where: t(x) = (1 + \xi(x - \mu)/\sigma)^{-1/\xi} \; for \; \xi \neq 0 \; and \; t(x) = \exp(-(x - \mu)/\sigma) \; for \; \xi = 0$$

When ξ=0, the distribution is a Type 1 distribution, sometimes called a Gumbel-type distribution. The random values of x are in the interval (–∞, ∞). When ξ=0, it is more efficient to use the GUMBEL option in the RAND function. When ξ>0, the distribution is a Type 2 distribution, sometimes called a Fréchet-type distribution. The random values of x are in the interval (μ– σ/ξ, ∞). When ξ<0, the distribution is a Type 3 distribution, sometimes called a Weibull-type distribution. The random values of x are in the interval (–∞, μ– σ/ξ).

μ

is a numeric location parameter.

Default 0

σ

is a numeric scale parameter.

Default 0

Range σ>0

ξ

is a numeric shape parameter.

Default 1

F Distribution

x = **RAND**('F', *n*, *d*)

Arguments

x

is an observation from the F distribution with the following probability density function:

$$f(x) = \frac{\Gamma\left(\frac{n+d}{2}\right)}{\Gamma\left(\frac{n}{2}\right)\Gamma\left(\frac{d}{2}\right)} \frac{n^{n/2} d^{d/2} x^{n/2-1}}{(d+nx)^{(n+d)/2}}$$

Range *x* > 0

n

is a numeric numerator degrees of freedom parameter.

Range *n* > 0

d

is a numeric denominator degrees of freedom parameter.

Range $d > 0$

Gamma Distribution

x = **RAND**('GAMMA', *a* [,λ])

Arguments

x

is an observation from the Gamma distribution with the following probability density function:

$$f(x) = \frac{x^{a-1}}{\lambda a \Gamma(a)} \exp(-x/\lambda)$$

Range $x > 0$

a

is a numeric constant, variable, or expression that specifies a shape parameter.

Range $a > 0$

λ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range λ>1

Geometric Distribution

x = **RAND**('GEOMETRIC', *p*)

Arguments

x

is a count that denotes the number of trials that are needed to obtain one success. This argument must be a whole number. *X* is an observation from the geometric distribution with the following probability density function:

$$f(x) = \begin{cases} (1-p)^{x-1}p & 0 < p < 1, x = 1, 2, \ldots \\ 1 & p = 1, x = 1 \end{cases}$$

Range $x = 1, 2, \ldots$

p

is a numeric probability of success.

Range $0 < p \leq 1$

Gompertz Distribution

x=**RAND**('GOMPERTZ',[λ,σ])

Arguments

x

is an observation from the Gompertz distribution and has the following cumulative probability distribution:

$$F(x) = 1 - \exp(-\lambda \exp(1/\sigma) - 1)$$

The random values of *x* are in the interval (0, ∞).

λ

is a numeric constant, variable, or expression that specifies a shape parameter.

Default 1

σ

is a numeric constant, variable, or expression that specifies a scale parameter.

Default 1

Range σ>0

Gumbel Distribution

x=RAND('GUMBEL',[μ, σ])

x

is an observation from the Gumbel distribution, and has the following cumulative probability distribution:

$$F(x) = \exp(-\exp(-(x-\mu)/\sigma))$$

The random values of x are in the interval (-∞, ∞). The Gumbel distribution is an extreme value distribution. The distribution is skewed to the right.

μ

is a numeric constant, variable, or expression that specifies a numeric location parameter.

Default 0

σ

is a numeric constant, variable, or expression that specifies a numeric scale parameter.

Default 1

Range σ>0

Hypergeometric Distribution

x = **RAND**('HYPER', *N*, *R*, *n*)

Arguments

x

is an observation from the hypergeometric distribution with the following probability density function. This argument must be a whole number.

$$f(x) = \frac{\binom{R}{x}\binom{N-R}{n-x}}{\binom{N}{n}}$$

Range $x = \max(0, (n - (N - R))), \ldots, \min(n, R)$

N

is a population size parameter. This argument must be a whole number.

Range $N = 1, 2, \ldots$

R

is a number of items in the category of interest. This argument must be a whole number.

Range $R = 0, 1, \ldots, N$

n

is a sample size parameter. This argument must be a whole number.

Range $n = 1, 2, \ldots, N$

The hypergeometric distribution is a mathematical formalization of an experiment in which you draw *n* balls from an urn that contains *N* balls, *R* of which are red. The hypergeometric distribution is the distribution of the number of red balls in the sample of *n*.

Integer Distribution

x=**RAND**('INTEGER',*a*,[*b*])

Arguments

x

is a random value from the discrete uniform distribution on a finite set of integers. If you specify one integer parameter, *a*, then *x* is drawn uniformly at random from the set {1,2,..., a-1, a}. If you specify two integer parameters, *a* and *b* with a≤b, then *x* is drawn uniformly at random from the set {a,a+1,..., b-1, b}.

a

is an integer parameter. If you specify only one numeric parameter, *a* is an upper limit for the random values. If you specify two parameters, *a* is a lower limit.

b

is an integer parameter that specifies the upper limit for the random values.

Laplace Distribution

x=**RAND**('LAPLACE',[*θ*,*λ*])

Arguments

x

is an observation from the Laplace distribution and has the following probability density function:

$$f(x) = \frac{1}{2\lambda}\exp\left(-\left|x-\theta\right|/\lambda\right)$$

θ

is an optional location parameter.

Default 0

λ

is an optional scale parameter

Default 0

Range λ>0

Logistic Distribution

x=**RAND**('LOGISTIC',[*θ*,*λ*])

Arguments

x

is an observation from the logistic distribution, which has the following probability density function:

$$f(x) = \frac{\exp(-(x-\theta)/\lambda)}{\lambda(1+\exp(-(x-\theta)/\lambda))^2}$$

θ

is an optional scale parameter.

Default 0

λ

is an optional scale parameter.

Default 0

Range λ>0

Lognormal Distribution

x = **RAND**('LOGNORMAL',[*θ*,*λ*])

Arguments

x

is an observation from the lognormal distribution with the following probability density function:

$$f(x) = \frac{1}{x\lambda\sqrt{2\,\pi}}\exp\left(\frac{-(\ln(x)-\theta)^2}{2\lambda^2}\right)$$

If the random variable *x* is lognormally distributed, then log (*x*) is normally distributed with mean θ and standard deviation λ.

Range $x > 0$

θ

is a numeric constant, variable, or expression that specifies a log-scale parameter.

Default 0

λ

is a numeric constant, variable, or expression that specifies a shape parameter.

Default 1

Range $\lambda > 0$

Negative Binomial Distribution

x = **RAND**('NEGBINOMIAL', *p*, *k*)

Arguments

x

is an observation from the negative binomial distribution with the following probability density function. This argument must be a whole number.

$$f(x) = \begin{cases} \binom{x+k-1}{k-1}(1-p)^x p^k & 0 < p < 1, x = 0, 1, \ldots \\ 1 & p = 1, x = 0 \end{cases}$$

Range $x = 0, 1, \ldots$

k

is a numeric parameter that is the number of successes. Integer and non-integer *k* values are allowed.

Range $k = 1, 2, \ldots$

p

is a numeric probability of success.

Range $0 < p \leq 1$

The negative binomial distribution is the distribution of the number of failures before *k* successes occur in sequential independent trials, all with the same probability of success, *p*.

Normal Distribution

x=**RAND**('NORMAL' [, *θ*, *λ*])

Arguments

x

is an observation from the normal distribution with a mean of θ and a standard deviation of λ that has the following probability density function:

$$f(x) = \frac{1}{\lambda\sqrt{2\,\pi}}\ exp\left(-\frac{(x-\theta)^2}{2\lambda^2}\right)$$

Range $-\infty < x < \infty$

θ

is the mean parameter.

Default 0

λ

is the standard deviation parameter.

Default 1

Range λ > 0

Pareto Distribution

x=**RAND**('PARETO', *a*,[*k*])

Arguments

x

is an observation from the Pareto distribution and has the following probability density function.

$$f\left(x\right) = \frac{a}{k}\left(\frac{k}{x}\right)a + 1$$

a

is a shape parameter.

Range $a>0$

k

is an optional scale parameter.

Default 1

Range $k>0$

Poisson Distribution

x = **RAND**('POISSON', *m*)

Arguments

x

is an observation from the distribution with the following probability density function. This argument must be a whole number.

$$f(x) = \frac{m^x e^{-m}}{x!}$$

Range x = 0, 1, ...

m

is a numeric mean parameter.

Range $m > 0$

Shifted Gompertz Distribution

x=**RAND**('SHGOMPERTZ', [η,τ])

Arguments

x

is an observation from the shifted Gompertz distribution and has the following cumulative probability distribution.

$$F(x) = (1 - \exp(-\tau x))\exp(-\eta \exp(-\tau x))$$

The random values of x are in the interval (0, ∞). As η→0, the shifted Gompertz distribution approaches the exponential distribution with shape parameter 1/τ.

η

is a shape parameter.

Default 1

Range η>0

τ

is an inverse scale parameter.

Default 1

Range τ>0

T Distribution

x = **RAND**('T', *df*)

Arguments

x

is an observation from the T distribution with the following probability density function:

$$f(x) = \frac{\Gamma\left(\frac{df+1}{2}\right)}{\sqrt{df\,\pi}\,\Gamma\left(\frac{df}{2}\right)}\left(1 + \frac{x^2}{df}\right)^{-\frac{df+1}{2}}$$

Range $-\infty < x < \infty$

df
is a numeric degrees of freedom parameter.

Range *df* > 0

Tabled Distribution

x = **RAND**('TABLE', *p1*, *p2*, ...)

Arguments

x
is an observation from one of the following distributions. This argument must be a whole number.

If $\sum_{i=1}^{n} p_i < 1$, then *x* is an observation from this probability density function:

$$f(i) = p_i, \quad i = 1, 2, \ldots, n$$

and

$$f(n+1) = 1 - \sum_{i=1}^{n} p_i$$

If $\sum_{i=1}^{n} p_i \geq 1$ for some index *n*, then *x* is an observation from this probability density function:

$$f(i) = p_i, \quad i = 1, 2, \ldots, n-1$$

and

$$f(n) = 1 - \sum_{i=1}^{n-1} p_i$$

p1, p2, ...
are numeric probability values.

Range 0 ≤ *p1, p2, ...* ≤ 1

Restriction The maximum number of probability parameters depends on your operating environment, but the maximum number of parameters is at least 32,767.

The tabled distribution takes on the values 1, 2, ..., *n* with specified probabilities.

Note: By using the FORMAT statement, you can map the set {1, 2, ..., *n*} to any set of *n* or fewer elements.

Triangular Distribution

x = **RAND**('TRIANGLE', *h*)

Arguments

x

is an observation from the triangular distribution with the following probability density function:

$$f(x) = \begin{cases} \frac{2x}{h} & 0 \le x \le h \\ \frac{2(1-x)}{1-h} & h < x \le 1 \end{cases}$$

In this equation, 0 ≤ *h* ≤ 1.

Range 0 ≤ *x* ≤ 1

Note The distribution can be easily shifted and scaled.

h

is the horizontal location of the peak of the triangle.

Range 0 ≤ *h* ≤ 1

Uniform Distribution

x = **RAND**('UNIFORM', [a,b])

Arguments

x

is an observation from the continuous uniform distribution in the interval (a,b). For a< b, the probability density function on (a,b) is:

$$f(x) = \frac{1}{|b-a|}$$

If you do not specify any parameters, then the interval (0,1) is used. If you specify one parameter, then the interval (0,c) is used, where c is the specified parameter. If you specify two parameters, then a < x < b, where a and b are the specified parameters.

Range 0 < *x* < 1

The RAND function uses the Mersenne-Twister random number generator (RNG) that was developed by Matsumoto and Nishimura (1998). Other random number generators can be specified by the STREAMINIT function.

The RAND function is started with a single seed. However, the state of the process cannot be captured by a single seed. You cannot stop and restart the generator from its stopping point.

For the default 32-bit Mersenne Twister, if the initial seed is exactly divisible by 8192, the RAND function uses the 2002 initialization algorithm (Matsumoto and Nishimura, 2002). Otherwise, RAND uses the 1998 initialization algorithm for compatibility with previous releases.

Wald (Inverse Gaussian) Distribution

x=**RAND**('WALD', λ,[θ])

x=**RAND**('IGAUSS', *λ*,[*θ*])

Arguments

x

is an observation from the Wald distribution and has the following probability density function:

$$f\left(x\right) = \left(\frac{\lambda}{2\pi x^3}\right)^{1/2} \exp\left(-\frac{\lambda(x-\theta)2}{2\theta^2 x}\right)$$

The random values of x are in the interval (0,∞). Many references, including the MCMC procedure in SAS/STAT software, list θ as the first parameter for the inverse Gaussian distribution. However, θ is the last parameter for the RAND, PDF, CDF, and QUANTILE functions because it is an optional parameter.

λ

is a shape parameter.

Range $\lambda>0$

θ

is the mean parameter.

Default 1

Range $\theta>0$

Weibull Distribution

x = **RAND**('WEIBULL', *a*, *b*)

Arguments

x

is an observation from the Weibull distribution with the following probability density function:

$$f(x) = \frac{a}{b^a} x^{a-1} e^{-\left(\frac{x}{b}\right)^a}$$

Range $x \geq 0$

a

is a numeric shape parameter.

Range $a > 0$

b

is a numeric scale parameter.

Range $b > 0$

Example

The following program illustrates the RAND function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c d e f g h i j k l m n o p q r s t u v;
   dcl double w x y z aa bb cc;
   method run();
      a=rand('BERN', .75);
      b=rand('BETA', 3, 1);
      c=rand('BINOM', 0.75, 10);
      d=rand('CAUCHY');
      e=rand('CHISQ', 22);
      f=rand('ERLANG', 7);
      g=rand('EXTRVAL', 0, 1);
      h=rand('EXPO');
      i=rand('F', 12, 322);
      j=rand('GAMMA', 7.25);
      k=rand('GEOM', 0.02);
      l=rand('GOMP', 1, 0.5);
      m=rand('GUMBEL', 0, 2);
      n=rand('HYPER', 10, 3, 5);
      o=rand('INTEGER', 1, 10);
      p=rand('LAPLACE');
      q=rand('LOGIST');
      r=rand('LOGN');
      s=rand('NEGB', 0.8, 5);
      t=rand('NORMAL');
      u=rand('PARETO', 3, 1);
      v=rand('POISSON', 6.1);
      w=rand('SHGOMP', 0.5, 1.2);
      x=rand('T', 4);
      y=rand('TABLE', .2, .5);
      z=rand('TRIANGLE',0.7);
      aa=rand('UNIFORM');
      bb=rand('WALD', 0.25, 2.1);
      cc=rand('WEIB', 1, 2);
      put a;
      put b;
      put c;
      put d;
      put e;
      put f;
      put g;
      put h;
      put i;
      put j;
      put k;
      put l;
      put m;
      put n;
```

```
        put o;
        put p;
        put q;
        put r;
        put s;
        put t;
        put u;
        put v;
        put w;
        put x;
        put y;
        put z;
        put aa;
        put bb;
        put cc;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log. Because the function is a random number generator, the results vary every time the program is run.

RANEXP Function

Returns a random variate from an exponential distribution.

Note: This function is no longer supported. Use the RAND('EXPONENTIAL') function on page 1071 instead.

RANGAM Function

Returns a random variate from a gamma distribution.

Note: This function is no longer supported. Use the RAND('GAMMA') function on page 1071 instead.

RANGE Function

Returns the difference between the largest and the smallest values.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

RANGE(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.

Data type: DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The RANGE function returns the difference between the largest and the smallest of the non-null or nonmissing arguments.

Example

The following program illustrates the RANGE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x0 x1 x2 x3 x4;
   method run();
      x0=range(., .);
      x1=range(-2, 6, 3);
      x2=range(2, 6 ,3, .);
      x3=range(1, 6, 3, 1);
      x4=range(of x1-x3);
      put x0= x1= x2= x3= x4=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x0=. x1=8 x2=4 x3=5 x4=4
```

RANK Function

Returns the position of a character in the ASCII collating sequence.

Category: Character

Returned data type: DOUBLE

Syntax

RANK(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The RANK function returns a whole number that represents the position of the character in the ASCII collating sequence. When more than one character is specified, the RANK function returns the position in the ASCII collating sequence for the first character.

Note: Any program that uses the RANK function with characters above ASCII 127 is not portable. (The hexadecimal notation is **'7F'x**.) The program is not portable because these characters are national characters and they vary from country to country.

Example

The following program illustrates the RANK function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl varchar x;
   method run();
      x=rank('A');
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following ASCII output to the log.

```
65
```

Functions:

- "BYTE Function" on page 344

RANNOR Function

Returns a random variate from a normal distribution.

Note: This function is no longer supported. Use the RAND('NORMAL') function on page 1071 instead.

RANPOI Function

Returns a random variate from a Poisson distribution.

Note: This function is no longer supported. Use the RAND('POISSON') function on page 1071 instead.

RANTBL Function

Returns a random variate from a tabled probability distribution.

Note: This function is no longer supported. Use the RAND('TABLE') function on page 1071 instead.

RANTRI Function

Returns a random variate from a triangular distribution.

Note: This function is no longer supported. Use the RAND('TRIANGLE') function on page 1071 instead.

RANUNI Function

Returns a random variate from a uniform distribution.

Note: This function is no longer supported. Use the RAND('UNIFORM') function on page 1071 instead.

REPEAT Function

Repeats a character expression.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

REPEAT(*expression*, *n*)

Required Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

n
specifies the number of times to repeat *expression*.

Restriction *n* must be greater than or equal to 0.

Data type BIGINT, DOUBLE

Details

The REPEAT function returns a character value consisting of the first argument repeated *n* times. Thus, the first argument appears *n*+1 times in the result.

Example

The following program illustrates the REPEAT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl varchar(10) x;
   method run();
      x=repeat('ONE', 2);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
ONEONEONE
```

REVERSE Function

Reverses a character expression.

Category:	Character
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

REVERSE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The REVERSE function returns a character value with the last character in the expression is the first character in the result, the next-to-last character in the expression is the second character in the result, and so on.

Note: Trailing blanks in the expression become leading blanks in the result.

Example

The following program illustrates the REVERSE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl varchar backward;
   method run();
      backward=reverse('xyz
');

      put backward=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
backward= zyx
```

RIGHT Function

Right aligns a character expression.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

RIGHT(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The RIGHT function returns an argument with trailing blanks moved to the start of the value. The argument's length does not change.

Example

The following programs illustrate the RIGHT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(10) a b c;
   method run();
      a='Due Date  ';
      b=put(a, $10.);
      c=put(right(a), $10.);
      put b;
      put c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Due Date
  Due Date
```

```
proc ds2;
data test(overwrite=yes);
   dcl char(12) a;
   dcl char(15) b;
```

```
      method run();
         a='Due Date  ';
         b='*'||right(a);
         put a= $12. b= $15.;
      end;
   run;
   quit;
```

SAS writes the following output to the log:

```
a=Due Date     b=*    Due Date
```

RMS Function

Returns the root mean square.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

RMS(*expression* [, ...*expression*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The root mean square is the square root of the arithmetic mean of the squares of the values. If all the arguments are null or missing values, then the result is a null or missing value. Otherwise, the result is the root mean square of the non-null or nonmissing values.

Let n be the number of arguments with non-null or nonmissing values, and let $x_1, x_2, \ldots, x_n$ be the values of those arguments. The root mean square is calculated as follows.

$$\sqrt{\frac{x_1^2 + x_2^2 + \ldots + x_n^2}{n}}$$

Example

The following program illustrates the RMS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;data test(overwrite=yes);
   dcl double x1 x2 x3;
   method run();
      x1=rms(1,7);
      x2=rms(.,1,5,11);
      x3=rms(of x1-x2);
      put x1=;
      put x2=;
      put x3=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=5
x2=7
x3=6.0827625302982
```

ROUND Function

Rounds the first argument to the nearest multiple of the second argument, or to the nearest integer when the second argument is omitted.

Category: Truncation

Returned data type: DOUBLE

Syntax

ROUND(*expression* [, *rounding-unit*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value, to be rounded.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

rounding-unit
specifies a positive numeric expression that specifies the rounding unit.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

Basic Concepts

The ROUND function rounds the first argument to a value that is very close to a multiple of the second argument. The results might not be an exact multiple of the second argument.

Differences between Binary and Decimal Arithmetic

Computers use binary arithmetic with finite precision. If you work with numbers that do not have an exact binary representation, computers often produce results that differ slightly from the results that are produced with decimal arithmetic.

For example, the decimal values 0.1 and 0.3 do not have exact binary representations. In decimal arithmetic, 3*0.1 is exactly equal to 0.3, but this equality is not true in binary arithmetic.

As the following example shows, if `a` is a float and `b` is a REAL, there is a difference between the two values.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl float a diff;
   dcl real b;
   method run();
      a=0.3;
      b=3*0.1;
      diff=a-b;
      put a=;
      put b=;
      put diff=;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log:

```
a=0.3
b=0.30000001192092;
diff=-1.192092896618E-8
```

The Effects of Rounding

Rounding by definition finds an exact multiple of the rounding unit that is closest to the value to be rounded. For example, 0.33 rounded to the nearest tenth equals 3*0.1 or 0.3 in decimal arithmetic. In binary arithmetic, 0.33 rounded to the nearest tenth equals 3*0.1, and not 0.3, because 0.3 is not an exact multiple of one tenth in binary arithmetic.

The ROUND function returns the value that is based on decimal arithmetic, even though this value is sometimes not the exact, mathematically correct result. In the example `ROUND(0.33,0.1)`, ROUND returns 0.3 and not 3*0.1.

Expressing Binary Values

If the characters "0.3" appear as a constant in a DS2 program, the value is computed as 3/10. To be consistent with the standard informat, `ROUND(0.33,0.1)` computes the result as 3/10, and the following statement produces the results that you would expect.

```
if round(x,0.1) = 0.3 then
   ... more DS2 statements ...
```

However, if you use the variable Y instead of the constant 0.3, as the following statement shows, the results might be unexpected depending on how the variable Y is computed.

```
if round(x,0.1) = y then
   ... more DS2 statements ...
```

If ROUND reads Y as the characters "0.3" using the standard informat, the result is the same as if a constant 0.3 appeared in the IF statement. If ROUND reads Y with a different informat, or if a program other than SAS reads Y, then there is no guarantee that the characters "0.3" would produce a value of exactly 3/10. Imprecision can also be caused by computation involving numbers that do not have

exact binary representations, or by porting tables from one operating environment to another that has a different floating-point representation.

If you know that Y is a decimal number with one decimal place, but are not certain that Y has exactly the same value as would be produced by the standard informat, it is better to use the following statement:

```
if round(x,0.1) = round(y,0.1) then
   ... more DS2 statements ...
```

Testing for Approximate Equality

You should not use the ROUND function as a general method to test for approximate equality. Two numbers that differ only in the least significant bit can round to different values if one number rounds down and the other number rounds up. Testing for approximate equality depends on how the numbers have been computed. If both numbers are computed to a high relative precision, you could test for approximate equality by using the ABS and the MAX functions, as the following example shows.

```
if abs(x-y) <= 1e-12 * max( abs(x), abs(y) ) then
   ... more DS2 statements ...
```

Producing Expected Results

In general, `ROUND(expression, rounding-unit)` produces the result that you expect from decimal arithmetic if the result has no more than nine significant digits and any of the following conditions are true:

- The rounding unit is an integer.
- The rounding unit is a power of 10 greater than or equal to 1e-15. [1]
- The result that you expect from decimal arithmetic has no more than four decimal places.

For example:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data rounding(overwrite=yes);
   method run();
      d1 = round(1234.56789,100)     - 1200;
      d2 = round(1234.56789,10)      - 1230;
      d3 = round(1234.56789,1)       - 1235;
      d4 = round(1234.56789,.1)      - 1234.6;
      d5 = round(1234.56789,.01)     - 1234.57;
      d6 = round(1234.56789,.001)    - 1234.568;
      d7 = round(1234.56789,.0001)   - 1234.5679;
      d8 = round(1234.56789,.00001)  - 1234.56789;
      d9 = round(1234.56789,.1111)   - 1234.5432;
      /* d10 has too many decimal places in the value for */
      /* rounding-unit.                                   */
```

1. If the rounding unit is less than one, ROUND treats it as a power of 10 if the reciprocal of the rounding unit differs from a power of 10 in at most the three or four least significant bits.

```
      d10 = round(1234.56789,.11111) - 1234.54321;
   end;
enddata;
run;
quit;

proc print data=rounding; run;
```

The following output shows the results.

Output 7.22 *Results of Rounding Based on the Value of the Rounding Unit*

Obs	d1	d2	d3	d4	d5	d6	d7	d8	d9	d10
1	0	0	0	0	0	0	0	0	0	0.012345

When the Rounding Unit Is the Reciprocal of an Integer

When the rounding unit is the reciprocal of an integer [1], the ROUND function computes the result by dividing by the integer. Therefore, you can safely compare the result from ROUND with the ratio of two integers, but not with a multiple of the rounding unit. Here is an example:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data rounding2(overwrite=yes);
   drop pi unit;
   method run();
      pi = arcos(-1);
      unit=1/7.;
      d1=round(pi,unit) - 22/7.;
      d2=round(pi, unit) - 22*unit;
   end;
enddata;
run;
quit;

proc print data=rounding2;
run;
```

The following output shows the results.

Output 7.23 *Results of Rounding by the Reciprocal of an Integer*

Obs	d1	d2
1	0	1.3323E-15

1. ROUND treats the rounding unit as a reciprocal of an integer if the reciprocal of the rounding unit differs from an integer in at most the three or four least significant bits.

Computing Results in Special Cases

The ROUND function computes the result by multiplying an integer by the rounding unit when all of the following conditions are true:

- The rounding unit is not an integer.
- The rounding unit is not a power of 10.
- The rounding unit is not the reciprocal of an integer.
- The result that you expect from decimal arithmetic has no more than four decimal places.

For example:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   method run();
      difference=round(1234.56789,.11111) - 11111*.11111;
      put difference=;
   end;
enddata;
run;
quit;
```

The following line is written to the SAS log:

```
difference=0
```

Computing Results When the Value Is Halfway between Multiples of the Rounding Unit

When the value to be rounded is approximately halfway between two multiples of the rounding unit, the ROUND function rounds up the absolute value and restores the original sign. For example:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   method run ();
      do i=8 to 17;
         value=0.5 - 10**(-i);
         round=round(value);
         output;
      end;
      do i=8 to 17;
         value=-0.5 + 10**(-i);
         round=round(value);
         output;
      end;
   end;
enddata;
```

```
run;
quit;

proc print data=test;
run;
```

The following output shows the results.

Output 7.24 *Results of Rounding When Values Are Halfway between Multiples of the Rounding Unit*

The SAS System

Obs	I	VALUE	ROUND
1	8	0.50000	0
2	9	0.50000	0
3	10	0.50000	0
4	11	0.50000	0
5	12	0.50000	0
6	13	0.50000	1
7	14	0.50000	1
8	15	0.50000	1
9	16	0.50000	1
10	17	0.50000	1
11	8	-0.50000	0
12	9	-0.50000	0
13	10	-0.50000	0
14	11	-0.50000	0
15	12	-0.50000	0
16	13	-0.50000	-1
17	14	-0.50000	-1
18	15	-0.50000	-1
19	16	-0.50000	-1
20	17	-0.50000	-1

The approximation is relative to the size of the value to be rounded, and is computed in a manner that is shown in the following example. This example code does not always produce results exactly equivalent to the ROUND function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data testfile(overwrite=yes);
   method run();
      do i = 1 to 17;
         value = 0.5 - 10**(-i);
         epsilon = min(1e-6, value * 1e-12);
         temp = value + .5 + epsilon;
         fraction = modz(temp, 1);
         round = temp - fraction;
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=testfile noobs;
   format value 19.16;
run;
```

Comparisons

The ROUND function is the same as the ROUNDE function except that when the first argument is halfway between the two nearest multiples of the second argument, ROUNDE returns an even multiple. ROUND returns the multiple with the larger absolute value.

The ROUNDZ function returns a multiple of the rounding unit without trying to make the result match the result that is computed with decimal arithmetic.

Example

The following program compares the results that are returned by the ROUND function with the results that are returned by the ROUNDE function. The output was generated from the Linux operating environment.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data results(overwrite=yes);
   dcl double x rounde round;
   method run();
      do x=0 to 4 by .25;
```

```
            Rounde=rounde(x);
            Round=round(x);
            output;
        end;
    end;
enddata;
run;
quit;

proc print data=results;
run;
```

The following output shows the results.

Output 7.25 *Results That Are Returned by the ROUND and ROUNDE Functions*

Obs	x	rounde	round
1	0.00	0	0
2	0.25	0	0
3	0.50	0	1
4	0.75	1	1
5	1.00	1	1
6	1.25	1	1

ROUNDE Function

Rounds the first argument to the nearest multiple of the second argument, and returns an even multiple when the first argument is halfway between the two nearest multiples.

Category: Truncation

Returned data type: DOUBLE

Syntax

ROUNDE(*expression* [, *rounding-unit*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value and that is to be rounded.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

rounding-unit
is a positive, numeric expression that specifies the rounding unit.

Default 1

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ROUNDE function rounds the first argument to the nearest multiple of the second argument.

Comparisons

The ROUNDE function is the same as the ROUND function except that when the first argument is halfway between the two nearest multiples of the second argument, ROUNDE returns an even multiple. ROUND returns the multiple with the larger absolute value.

Example

The following program compares the results that are returned by the ROUNDE function with the results that are returned by the ROUND function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data results(overwrite=yes);
   dcl double x rounde round;
   method run();
      do x=0 to 4 by .25;
         rounde=rounde(x);
         round=round(x);
         output;
      end;
   end;
enddata;
run;
quit;
```

The following output shows the results.

Output 7.26 *Results That Are Returned by the ROUNDE and ROUND Functions*

ROUNDZ Function

Rounds the first argument to the nearest multiple of the second argument, using zero fuzzing.

Category: Truncation

Returned data type: DOUBLE

Syntax

ROUNDZ(*expression* [, *rounding-unit*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

rounding-unit
specifies any valid expression that evaluates to a numeric expression and that specifies the rounding unit.

Default 1

Requirement Only positive values are valid.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The ROUNDZ function rounds the first argument to the nearest multiple of the second argument.

Comparisons

The ROUNDZ function is the same as the ROUND function with these exceptions:

- ROUNDZ returns an even multiple when the first argument is exactly halfway between the two nearest multiples of the second argument. ROUND returns the multiple with the larger absolute value when the first argument is approximately halfway between the two nearest multiples.
- When the rounding unit is less than one and not the reciprocal of an integer, the result that is returned by ROUNDZ might not agree exactly with the result from decimal arithmetic. ROUNDZ does not fuzz the result. ROUND performs extra computations, called fuzzing, to try to make the result agree with decimal arithmetic.

Examples

Example 1: Comparing Results from the ROUNDZ and ROUND Functions

The following program compares the results that are returned by the ROUNDZ and the ROUND function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double i value roundz round;
   method run();
      do i=10 to 17;
         Value=2.5 - 10**(-i);
         Roundz=roundz(value);
         Round=round(value);
         output;
      end;
      do i=16 to 12 by -1;
         value=2.5 + 10**(-i);
         roundz=roundz(value);
         round=round(value);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=test;
format value 19.16;
quit;
```

The following output shows the results.

Output 7.27 *Results That Are Returned by the ROUNDZ and ROUND Functions*

Obs	i	value	roundz	round
1	10	2.4999999999000000	2	2
2	11	2.4999999999900000	2	2
3	12	2.4999999999990000	2	3
4	13	2.4999999999999000	2	3
5	14	2.4999999999999900	2	3

8	17	2.5000000000000000	2	3
9	16	2.5000000000000000	2	3
10	15	2.5000000000000000	3	3
11	14	2.5000000000000100	3	3
12	13	2.5000000000001000	3	3
13	12	2.5000000000010000	3	3

Example 2: Sample Output from the ROUNDZ Function

The following program illustrates the ROUNDZ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x a b c d e;
   method run();
      x=223.456;
      a=roundz(x,1);
      b=roundz(x, .01);
      c=roundz(x, 100);
      d=roundz(x);
      e=roundz(x, .3);
      put a= b= c= d= e=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=223 b=223.46 c=200 d=223 e=223.5
```

SASLOGLINENUMBER Function

Returns the line number of the current statement in the SAS log.

Category:	Special
Returned data type:	INTEGER

Syntax

SASLOGLINENUMBER( )

Without Arguments

The SASLOGLINENUMBER() function has no arguments.

Details

The SASLOGLINENUMBER function returns the line number of the current statement in the SAS log. For stored packages or stored threads that are not listed in the SAS log, SASLOGLINENUMBER returns the line number of the current statement, offset from the PACKAGE statement for stored packages or the THREAD statement for stored threads.

Example

The following program illustrates the SASLOGLINENUMBER function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
resetline;
proc ds2;
thread testthread / overwrite=yes;
   dcl char a;
```

```
   dcl int threadlogline;
   method init();
         a = 'apple';
      threadlogline = sasloglinenumber();
      put threadlogline=;
   end;
endthread;

data _null_;
   dcl thread testthread t();
   dcl int datalogline;
   dcl char b;
   method init();
      b = 'banana';
      datalogline = sasloglinenumber();
      put datalogline=;
   end;

   method run();
      set from t threads = 1;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log.

```
78   resetline;
1    proc ds2;
2
3    thread testthread / overwrite=yes;
4      dcl char a;
5      dcl int threadlogline;
6      method init();
7    a = 'apple';
8        threadlogline = sasloglinenumber();
9    put threadlogline=;
10     end;
11   endthread;
12
13   data _null_;
14   dcl thread testthread t();
15   dcl int datalogline;
16   dcl char b;
17     method init();
18       b = 'banana';
19       datalogline = sasloglinenumber();
20     put datalogline=;
21     end;
22
23     method run();
24   set from t threads = 1;
25     end;
26   enddata;
27   run;
27 !      quit;
datalogline=19
threadlogline=8
```

SAVING Function

Returns the future value of a periodic saving.

Category: Financial

Returned data type: DOUBLE

Syntax

SAVING(*f*, *p*, *r*, *n*)

Required Arguments

f

is numeric, the future amount (at the end of *n* periods).

Range $f \geq 0$

Data type DOUBLE

p

is numeric, the fixed periodic payment.

Range $p \geq 0$

Data type DOUBLE

r

is numeric, the periodic interest rate expressed as a decimal.

Range $r \geq 0$

Data type DOUBLE

n

is an integer, the number of compounding periods.

Range $n \geq 0$

Data type DOUBLE

Details

The SAVING function returns the missing argument in the list of four arguments from a periodic saving. The arguments are related by the following equation:

$$f = \frac{p(1+r)\left((1+r)^n - 1\right)}{r}$$

One missing argument must be provided. It is then calculated from the remaining three. No adjustment is made to convert the results to round numbers.

Example

A savings account pays a 5% nominal annual interest rate, compounded monthly. For a monthly deposit of $100, the number of payments that are needed to accumulate at least $12,000 can be expressed as follows:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a;
   method run();
      a=saving(12000, 100, .05/12, .);
      put  'a= ' a;
   end;
enddata;
run;
quit;
```

The value that is returned is 97.18 months. The fourth argument is set to missing, which indicates that the number of payments is to be calculated. The 5% nominal annual rate is converted to a monthly rate of 0.05/12. The rate is the fractional (not the percentage) interest rate per compounding period.

Functions:

- “SAVINGS Function” on page 1119

SAVINGS Function

Returns the balance of a periodic savings by using variable interest rates.

Category: Financial

Returned data type: DOUBLE

Syntax

SAVINGS(*base-date*, *initial-deposit-date*, *deposit-amount*, *deposit-number*, *deposit-interval*, *compounding-interval*, *date-1*, *rate-1*[, ...*date-n*, *rate-n*])

Required Arguments

base-date
specifies the value that is returned is the balance of the savings at the base date.

Requirement *Base-date* is a SAS date.

Data type DOUBLE

initial-deposit-date
specifies the date of the first deposit. Subsequent deposits are at the beginning of subsequent deposit intervals.

Requirement *Initial-deposit-date* is a SAS date.

Data type DOUBLE

deposit-amount
specifies the value of each deposit. All deposits are assumed constant.

Data type DOUBLE

deposit-number
specifies the number of deposits.

Data type DOUBLE

deposit-interval
specifies the frequency at which deposits are made.

Requirement *Deposit-interval* is a SAS interval.

Data type CHAR

compounding-interval
specifies the compounding interval.

Requirement *Compounding-interval* is a SAS interval.

Data type CHAR

date
specifies the time at which *rate* takes effect. Each date is paired with a rate.

Requirement *Date* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate as numeric percentage that starts on *date*. Each rate is paired with a date.

Data type DOUBLE

Details

The following details apply to the SAVINGS function:

- The values for rates must be between –99 and 120.
- *Deposit-interval* cannot be 'CONTINUOUS'.
- The list of date-rate pairs does not need to be in chronological order.
- When multiple rate changes occur on a single date, the SAVINGS function applies only the final rate that is listed for that date.
- Simple interest is applied for partial periods.
- There must be a valid date-rate pair whose date is at or prior to both the *initial-deposit-date* and the *base-date*.

Example

- If you deposit $300 monthly for two years into an account that compounds quarterly at an annual rate of 4%, the balance of the account after five years can be expressed as follows:

```
proc ds2;
data _null_;
   dcl double bd idd d amount_base1;
   method run();
      bd=to_double(date'2005-01-01');
      idd=to_double(date'2000-01-01');
      d=to_double(date'2000-01-01');
      amount_base1=savings(bd, idd, 300, 24, 'month', 'qtr', d, 4.00);
      put amount_base1;
   end;
enddata;
run;
quit;
```

The following line is written to the SAS log.

```
8458.79415896917
```

- If the interest rate increases by a quarter-point each year, then the balance of the account could be expressed as follows:

```
proc ds2;
data _null_;
   dcl double bd idd d1 d2 d3 d4 d5 amount_base2;
   method run();
      bd= to_double(date'2005-01-01');
      idd= to_double(date'2000-01-01');
      d1= to_double(date'2000-01-01');
      d2= to_double(date'2001-01-01');
      d3= to_double(date'2002-01-01');
      d4= to_double(date'2003-01-01');
      d4= to_double(date'2004-01-01');
      amount_base2 = savings(bd, idd, 300, 24, 'month', 'qtr', d1,
4.00, d2,
         4.25, d3, 4.50, d4, 4.75, d5, 5.0);
      put amount_base2;
   end;
enddata;
run;
quit;
```

The following line is written to the SAS log.

```
8623.09024586998
```

- To determine the balance after one year of deposits, the following program sets amount_base3 to the desired balance:

```
proc ds2;
data _null_;
   dcl double bd idd d amount_base3;
   method run();
      bd= to_double(date'2001-01-01');
      idd= to_double(date'2000-01-01');
      d= to_double(date'2000-01-01');
      amount_base3 = savings(bd, idd, 300, 24, 'month', 'qtr', d, 4);
      put amount_base3;
   end;
enddata;
run;
quit;
```

The following line is written to the SAS log.

```
3978.69037121739
```

The SAVINGS function ignores deposits after the base date, so the deposits after the reference date do not affect the value that is returned.

SCAN Function

Returns the *n*th word from a character expression.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

SCAN(*expression*, *n* [, *delimiters*[, *modifier*]])

Required Arguments

expression

specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

n

is a nonzero numeric expression that specifies the number of the word in the character expression that you want SCAN to select. The following rules apply: If *n* is positive, SCAN counts words from left to right in the character string. If *n* is negative, SCAN counts words from right to left in the character string. If *n* is greater than the number of words in *expression*, SCAN returns a blank value.

is a nonzero numeric expression that specifies the number of the word in the character expression that you want SCAN to select. The following rules apply:

- If *n* is positive, SCAN counts words from left to right in the character string.
- If *n* is negative, SCAN counts words from right to left in the character string.
- If *n* is greater than the number of words in *expression*, SCAN returns a blank value.

Optional Arguments

delimiters

specifies any valid expression that evaluates or can be coerced to a character string and that SCAN uses as word separators in the expression.

Default

Requirement If *delimiter* is a constant, enclose *delimiter* in single quotation marks.

Interactions ASCII default delimiters are: blank ! $ % & ( ) * + , – . / ; < |. In environments without the ^ character, SCAN uses the ~ character instead.

Specifying a modifier can change the characters in *delimiter*. For example, if you specify the K modifier in the *modifier* argument, all characters that are not in *delimiter* are used as delimiters.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Tip You can add more characters to *delimiter* by using other modifiers.

See "Using Default Delimiters in an ASCII Environment" on page 1126

"DS2 Expressions" in *SAS DS2 Programmer's Guide*

modifier

specifies a character constant, variable, or expression in which each non-blank character modifies the action of the SCAN function. Blanks are ignored and the characters are not case sensitive. Use the following characters as modifiers:

A

adds alphabetic characters to the list of characters.

B

scans backward from right to left instead of from left to right, regardless of the sign of the *count* argument.

C

adds control characters to the list of characters.

D

adds digits to the list of characters.

F

adds an underscore and English letters to the list of characters.

G

adds graphic characters to the list of characters. Graphic characters are characters that, when printed, produce an image on paper.

H

adds a horizontal tab to the list of characters.

I

ignores the case of the characters.

K

causes all characters that are not in the list of characters to be treated as delimiters. That is, if K is specified, characters that are in the list of characters are kept in the returned value rather than being omitted because they are delimiters. If K is not specified, then all characters that are in the list of characters are treated as delimiters.

L

adds lowercase letters to the list of characters.

M

specifies that multiple consecutive delimiters, and delimiters at the beginning or end of the *string* argument, refer to words that have a length of zero. If the M modifier is not specified, then multiple consecutive delimiters are treated as one delimiter, and delimiters at the beginning or end of the *string* argument are ignored.

N

adds digits, an underscore, and English letters to the list of characters.

O

processes the *charlist* and *modifier* arguments only once, rather than every time the SCAN function is called. Using the O modifier in the DATA step (excluding WHERE clauses), or in the SQL procedure can make SCAN run faster when you call it in a loop where the *character-list* and *modifier* arguments do not change. The O modifier applies separately to each instance of the SCAN function in your SAS code, and does *not* cause all instances of the SCAN function to use the same delimiters and modifiers.

P

adds punctuation marks to the list of characters.

Q

ignores delimiters that are inside substrings that are enclosed in quotation marks. If the value of the *string* argument contains unmatched quotation marks, then scanning from left to right produces different words than scanning from right to left.

R

removes leading and trailing blanks from the word that SCAN returns. If you specify the Q and R modifiers, the SCAN function first removes leading and trailing blanks from the word. Then, if the word begins with a quotation mark, SCAN also removes one layer of quotation marks from the word.

S

adds space characters to the list of characters (blank, horizontal tab, vertical tab, carriage return, line feed, and form feed).

T

trims trailing blanks from the *string* and *charlist* arguments. If you want to remove trailing blanks from only one character argument instead of both character arguments, use the TRIM function instead of the SCAN function with the T modifier.

U

adds uppercase letters to the list of characters.

W

adds printable (writable) characters to the list of characters.

X

adds hexadecimal characters to the list of characters.

Restriction This argument is supported only in the SAS Viya platform.

Tip If the *modifier* argument is a character constant, enclose the argument in quotation marks. Specify multiple modifiers in a single

set of quotation marks. A *modifier* argument can also be expressed as a character variable or expression.

Details

Definitions of “Delimiter” and “Word”

A *delimiter* is any of several characters that are used to separate words. You can specify the delimiters in the *delimiter* and *modifier* arguments.

If you specify the Q modifier, delimiters inside substrings that are enclosed in quotation marks are ignored.

In the SCAN function, “word” refers to a substring that has all of these characteristics:

- It is bounded on the left by a delimiter or the beginning of the string.
- It is bounded on the right by a delimiter or the end of the string.
- It contains no delimiters.

A word can have a length of zero if there are delimiters at the beginning or end of the string, or if the string contains two or more consecutive delimiters. However, the SCAN function ignores words that have a length of zero unless you specify the M modifier.

Note: The definition of “word” is the same in the SCAN and COUNTW functions.

Using Default Delimiters in an ASCII Environment

If you use the SCAN function with only two arguments, then the default delimiters depend on whether your computer uses ASCII or EBCDIC characters.

- If your computer uses ASCII characters, here are the default delimiters:

  blank ! $ % & ( ) * + , - . / ; < ^ |

If you use the *modifier* argument without specifying any characters as delimiters, then the only delimiters that are used are delimiters that are defined by the *modifier* argument. In this case, the lists of default delimiters for ASCII environments are not used. In other words, modifiers add to the list of delimiters that are explicitly specified by the *delimiter* argument. Modifiers do not add to the list of default modifiers.

The Length of the Result

Leading delimiters before the first word in the expression do not affect SCAN. If there are two or more contiguous delimiters, SCAN treats them as one.

In DS2, if the SCAN function returns a value to a variable that has not yet been given a length, and then that variable is given the length of the first argument. If you need the SCAN function to assign to a variable a value that is different from

the length of the first argument, use a DECLARE statement for that variable before the statement that uses the SCAN function.

The minimum length of the word that is returned by the SCAN function depends on whether the M modifier is specified. See "Using the SCAN Function with the M Modifier" on page 1127. See also "Using the SCAN Function Without the M Modifier" on page 1127.

Using the SCAN Function with the M Modifier

If you specify the M modifier, the number of words in a string is defined as one plus the number of delimiters in the string. However, if you specify the Q modifier, delimiters that are inside quotation marks are ignored.

If you specify the M modifier, the SCAN function returns a word with a length of zero if one of these conditions is true:

- The string begins with a delimiter and you request the first word.
- The string ends with a delimiter and you request the last word.
- The string contains two consecutive delimiters and you request the word that is between the two delimiters.

Using the SCAN Function Without the M Modifier

If you do not specify the M modifier, the number of words in a string is defined as the number of maximal substrings of consecutive non-delimiters. However, if you specify the Q modifier, delimiters that are inside quotation marks are ignored.

If you do not specify the M modifier, the SCAN function acts in these ways:

- It ignores delimiters at the beginning or end of the string.
- It treats two or more consecutive delimiters as if they were a single delimiter.

If the string contains no characters other than delimiters, or if you specify a count that is greater in absolute value than the number of words in the string, then the SCAN function returns one of the following items:

- a single blank when you call the SCAN function from a DATA step
- a string with a length of zero when you call the SCAN function from the macro processor

Using Null Arguments

The SCAN function allows character arguments to be null. Null arguments are treated as character strings with a length of zero. Numeric arguments cannot be null.

Processing SBCS and DBCS Data

The SCAN function is designed to process SBCS data, but it can also process DBCS data. Here are the criteria:

- If *expression* is not declared as VARCHAR and you are processing single-byte data, then SCAN processes SBCS.

- If *string* is declared as VARCHAR and you are processing multibyte data, then SCAN processes DBCS.

Examples

Example 1: Finding the First and Last Words in a String

This example scans a string for the first and last words:

- A negative count instructs the SCAN function to scan from right to left.
- Leading and trailing delimiters are ignored because the M modifier is not used.
- In the last observation, all characters in the string are delimiters.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl varchar(8) first_word last_word;
   dcl varchar(29) string1 string2 string3 string4;
   dcl double i;
   method run();
      string1='Jack and Jill';
      first_word=scan(string1, 1);
      last_word=scan(string1, -1);
      put first_word= last_word=;
      string2='& Bob & Carol & Ted & Alice &';
      first_word=scan(string2, 1);
      last_word=scan(string2, -1);
      put first_word= last_word=;
      string3='Leonardo';
      first_word=scan(string3, 1);
      last_word=scan(string3, -1);
      put first_word= last_word=;
      string4='! $ % & ( ) * , - . / ;';
      first_word=scan(string4, 1);
      last_word=scan(string4, -1);
      put first_word= last_word=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
first_word=Jack last_word=Jill
first_word=Bob last_word=Alice
first_word=Leonardo last_word=Leonardo
first_word=  last_word=
```

Example 2: Finding All Words in a String Without Using the M Modifier

This example scans a string from left to right until the word that is returned is blank. Because the M modifier is not used, the SCAN function does not return any words that have a length of zero. Because blanks are included among the default delimiters, the SCAN function returns a blank word only when the count exceeds the number of words in the string. Therefore, the loop can be stopped when SCAN returns a blank word.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(drop=(string) overwrite=yes);
   dcl varchar(47) string word;
   dcl double count;
   method run();
      string=' The quick brown fox jumps over the lazy dog.   ';
      do until(word=' ');
         count+1;
         word=scan(string, count);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=test;
run;
```

Obs	word	count
1	The	1
2	quick	2
3	brown	3
4	fox	4
5	jumps	5
6	over	6
7	the	7
8	lazy	8
9	dog	9
10		10

Example 3: Finding All Words in a String by Using the M and O Modifiers

This example shows the results of using the M modifier with a comma as a delimiter. With the M modifier, leading, trailing, and multiple consecutive delimiters cause the SCAN function to return words that have a length of zero. Therefore, do not end the loop by testing for a blank word. Instead, use the COUNTW function with the same modifiers and delimiters to count the words in the string.

The O modifier is used for efficiency because the delimiters and modifiers are the same in every call to the SCAN and COUNTW functions.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data comma(keep=(count word) overwrite=yes);
   dcl varchar(45) string;
   dcl varchar(20) delim modif word;
   dcl double nwords count;
   method run();
      string=',leading, trailing,and multiple,,delimeters,,';
      delim=',';
      modif='mo';
      nwords=countw(string, delim, modif);
      put nwords=;
      do count=1 to nwords;
         word=scan(string, count, delim, modif);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=comma;
run;
```

Obs	word	count
1		1
2	leading	2
3	trailing	3
4	and multiple	4
5		5
6	delimeters	6
7		7
8		8

Example 4: Using Comma-Separated Values, Substrings in Quotation Marks, and the O and R Modifiers

This example uses the SCAN function with the O modifier and a comma as a delimiter, both with and without the R modifier.

The O modifier is used for efficiency because in each call of the SCAN or COUNTW function, the delimiters and modifiers do not change. The O modifier applies separately to each of the two instances of the SCAN function:

- The first instance of the SCAN function uses the same delimiters and modifiers every time SCAN is called.

- The second instance of the SCAN function uses the same delimiters and modifiers every time SCAN is called.
- The first instance of the SCAN function does not use the same modifiers as the second instance, but this fact has no bearing on the use of the O modifier.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(keep=(word word_r count) overwrite=yes);
   dcl varchar(40) string;
   dcl varchar(20) word word_r;
   dcl varchar delim modif;
   dcl double count nwords;
   method run();
      string='Hello, "She said, ""Hi!""", not "Bye!"';
      delim=',';
      modif='oq';
      nwords=countw(string, delim, modif);
      do count=1 to nwords;
         word=scan(string, count, delim, modif);
         word_r=scan(string, count, delim, modif||'r');
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=test;
run;
```

Obs	word	word_r	count
1	Hello	Hello	1
2	"She said, ""Hi!"""	She said, "Hi!"	2
3	not "Bye!"	not "Bye!"	3

Example 5: Finding Substrings of Digits by Using the D and K Modifiers

This example finds substrings of digits. The character-list argument is null. Consequently, the list of characters is initially empty. The D modifier adds digits to the list of characters. The K modifier treats all characters that are not in the list as delimiters. Therefore, all characters except digits are delimiters.

Note: In this example, code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(keep=(count digits) overwrite=yes);
   dcl char(25) string digits;
   dcl double count;
```

```
   method run();
      string='Call (800) 555-1234 now!';
      do until(digits=' ');
         count+1;
         digits=scan(string, count, '', 'dko');
         output;
      end;

   end;
enddata;
run;
quit;

proc print data=test;
run;
```

Obs	digits	count
1	800	1
2	555	2
3	1234	3
4		4

Example 6: Finding All Words in a String by Using the M and O Modifiers

This example shows the results of using the M modifier with a comma as a delimiter. With the M modifier, leading, trailing, and multiple consecutive delimiters cause the SCAN function to return words that have a length of zero. Therefore, do not end the loop by testing for a blank word. Instead, use the COUNTW function with the same modifiers and delimiters to count the words in the string.

The O modifier is used for efficiency because the delimiters and modifiers are the same in every call to the SCAN and COUNTW functions.

Note: This example is valid only in the SAS Viya platform.

```
cas;

proc ds2 sessref=casauto;
data comma (keep= (count word) overwrite=yes);
   dcl char(45) string;
   dcl char(12) delim modif word;
   dcl double nwords count;
   method run();
      string=',leading, trailing,and multiple,,delimiters,,';
      delim=',';
      modif='mo';
      nwords=countw(string, delim, modif);
      do count=1 to nwords;
         word=scan(string, count, delim, modif);
         output;
      end;
   end;
```

```
enddata;
run;
quit;

libname mycas cas sessref=casauto;
proc print data=mycas.comma;
run;
```

SDF Function

Returns a survival function.

Category: Probability

See: "CDF Function" on page 362

Syntax

SDF(*'distribution'*, *quantile*, *parameter-1, ..., parameter-k*)

Required Arguments

distribution
is a character string that identifies the distribution.

Note: The arguments for each of the SDF distribution functions are identical to those of the corresponding CDF distribution functions.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'

Distribution	Argument
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL'|'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD'|'IGAUSS'

Distribution	Argument
Weibull	'WEIBULL'

Note Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

quantile
is a numeric constant, variable, or expression that specifies the value of a random variable.

Data type DOUBLE

parameter-1, ..., parameter-k
are optional *shape*, *location*, or *scale* parameters appropriate for the specific distribution.

Data type DOUBLE

Details

The SDF function computes the survival function (upper tail) from various continuous and discrete distributions. For more information, see the individual distributions listed in the table above.

The SDF function for the Conway-Maxwell-Poisson distribution has the following form:

SDF('CONMAXPOI',*y*,*λ*,*v*)

y
is a nonnegative, whole number that represents counts data.

λ
is similar to the mean, as in the Poisson distribution.

v
is a dispersion parameter.

The SDF function returns the probability that the counts value is greater than *y*.

For more information, see "Conway-Maxwell-Poisson" distribution in the PDF function on page 941.

Example

The following program illustrates the SDF function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null;
   dcl double y;
   method run();
      y=sdf('BERN', 0, .25);
      put 'Bern dist:      ' y;
      y=sdf('BETA', 0.2, 3,4);
      put 'Beta dist:      ' y;
      y=sdf('BINOM', 4, .5, 10);
      put 'Binom dist:     ' y;
      y=sdf('CAUCHY', 2);
      put 'Cauchy dist:    ' y;
      y=sdf('CHISQ', 11.264, 11);
      put 'Chisq dist:     ' y;
      y=sdf('CONMAXPOI', 12, 2.3, .4);
      put 'Conmaxpoi dist: ' y;
      y=sdf('EXPO', 1);
      put 'Expo dist:      ' y;
      y=sdf('F', 3.32, 2,3);
      put 'F dist:         ' y;
      y=sdf('GAMMA', 1, 3);
      put 'Gamma dist:     ' y;
      y=sdf('GENPOISSON', .9, 1, .7);
      put 'Genpoisson dist:' y;
      y=sdf('GEOMETRIC', .5, .3);
      put 'Geometric dist: ' y;
      y=sdf('HYPER', 2, 200, 50, 10);
      put 'Hyper dist:     ' y;
      y=sdf('LAPLACE',1);
      put 'Laplace dist:   ' y;
      y=sdf('LOGISTIC', 1);
      put 'Logistic dist:  ' y;
      y=sdf('LOGNORMAL', 1);
      put 'LogNormal dist: ' y;
      y=sdf('NEGB', 1, .5,2);
      put 'NegB dist:      ' y;
      y=sdf('NORMAL', 1.96);
      put 'Normal dist:    ' y;
      y=sdf('NORMALMIX', 2.3, 3, .33, .33, .34, .5, 1.5, 2.5, .79,
1.6, 4.3);
      put 'Normal mix dist:' y;
      y=sdf('PARETO', 1, 1);
      put 'Pareto dist:    ' y;
      y=sdf('POISSON', 2, 1);
      put 'Poisson dist:   ' y;
      y=sdf('T', .9, 5);
      put 'T dist:         ' y;
      y=sdf('TWEEDIE', .8, 5);
      put 'Tweedie dist:   ' y;
      y=sdf('UNIFORM', 0.25);
      put 'Uniform dist:   ' y;
      y=sdf('WALD', 1, 2);
      put 'Wald dist:      ' y;
```

```
        y=sdf('WEIBULL', 1, 2);
        put 'Weibull dist:    ' y;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Bern dist:       0.25
Beta dist:       0.90112
Binom dist:      0.62304687499999
Cauchy dist:     0.14758361765043
Chisq dist:      0.42141867068269
Conmaxpoi dist:  0.19705138765343
Expo dist:       0.36787944117144
F dist:          0.17360663977568

SEC Function

Returns the secant.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

SEC(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value that expressed in radians.

Restriction *expression* cannot be an odd multiple of PI/2.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Comparisons

The SEC function is related to the COS function:

```
sec(x)=1/cos(x)
```

Example

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
 proc ds2;
data _null_;
   dcl double x y z;
   method run();
      x=sec(0.5);
      y=sec(0);
      z=sec(3.14159/3);
      put x= y= z=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=1.13949392732454 y=1 z=1.99999693590391
```

SECOND Function

Returns the second from a SAS time or datetime value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

SECOND(*time* | *datetime*)

Required Arguments

time
specifies any valid expression that represents a SAS time value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

datetime
specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The SECOND function produces a numeric value that represents a specific second of the minute. The result can be any number that is >= 0 and < 60.

Examples

Example 1: Basic SECOND Function Usage

The following program illustrates the SECOND function:

Note: In this example, code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b c d e f;
   method run();
      a=hms(3,19,24);
      b=second(a);
      put b=;
      c=hms(6,25,65);
      d=second(c);
      put d=;
      e=hms(3,19,60);
      f=second(e);
      put f=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
b=24
d=5
f=0
```

Example 2: Displaying the Second of the Minute That Is Associated with the Current Date and Time

This program specifies the second of the minute that is associated with datetime. The first three digits for the milliseconds, 876, are relevant.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=second(datetime());
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=18.8769989013671
```

- "MINUTE Function" on page 863

SETTHREADERRORSTATUS Function

Sets a user-specified error status value for non-fatal runtime errors, and optionally logs a user-specified message to the SAS log.

Category: Error Checking

Requirement: The SETTHREADERRORSTATUS function is used in conjunction with the GETTHREADERRORSTATUS function on page 687.

Returned data type: INTEGER

Note: Error messages generated by the SETTHREADERRORSTATUS function are caught by the App.TableServices.DS2.Runtime.Log logger. For more information about this logger, see "Run-Time Loggers" in *SAS DS2 Programmer's Guide*.

Syntax

SETTHREADERRORSTATUS(*status-value*[, *'string'*])

Required Argument

status-value
specifies any integer.

Optional Argument

'string'
specifies an optional user-defined ERROR message. The function prepends the word ERROR to the specified text, so there is no need to include it in the message string.

Data type: CHARACTER, NCHAR, NVARCHAR, VARCHAR

Notes

Messages longer than 500 characters are truncated, unless MSGORDER=TEMPORAL is set in the DS2_OPTIONS statement. When MSGORDER=TEMPORAL is set, the full error message is reported to the log, regardless of the length.

All messages are printed to the log with the ERROR prefix, even when SETTHREADERRORSTATUS specifies an error status value of 0.

Details

The SETTHREADERRORSTATUS function enables you to set a user-specified status value and optional user-specified ERROR message for the error status variable queried by the GETTHREADERRORSTATUS function. You can use the function to specify a custom error status value, or to explicitly reset the internal status variable to 0 (zero).

The function returns an integer to indicate whether the status value was set successfully or the function failed. A value of 0 indicates the function was successful; a value of 1 indicates an error occurred.

The SETTHREADERRORSTATUS function sets the error status value for only one thread. If multiple threads are running the DS2 THREAD block and DS2 DATA block, this function updates only the error status value of the current thread. The error status value of other threads are not impacted.

The automatic variables _N_ and _THREADID_ cannot be specified directly in a text string; however, the CAT function on page 346 can be used to construct a text string that includes them.

Example: Specifying an ERROR Message with the SETTHREADERRORSTATUS Function

This example is the same as "Example 2: Using the GETTHREADERRORSTATUS Function in a Threaded Program" except this example specifies the error message for the custom error condition in the SETTHREADERRORSTATUS function 'STRING' argument instead of in the PUT statement.

```
proc ds2;
   data largeNumberSet (overwrite=yes);
   dcl int row;

   method run();
   dcl int x;
     do x = 1 to 10000;
        if (mod(x, 1000) = 0) then row = NULL;
        else row = x;
        output;
     end;
   end;
```

```
enddata;
run;
quit;

proc ds2;
   thread processDataset / overwrite=yes;
   dcl int partial_sum;
   dcl char(100) msg;
   retain partial_sum;

   /* Set the partial sum to 0 */
   method init();
   partial_sum = 0;
   end;

   /* Start processing each row */
   method run();
   set largeNumberSet;
   if (missing(row) or null(row)) then
      do;
      msg = cat('Null value in row ', _n_, ' thread ', _threadid_);
      setThreadErrorStatus(4, msg);
      end;
   if (getThreadErrorStatus() = 0) then partial_sum = partial_sum +
row;
   end;

   method term();
   output;
   end;
endthread;

data _null_;
   dcl bigint summation;
   dcl thread processDataset t;
   retain summation;
/* Initialize summation to 0 */
method init();
summation = 0;
end;
method run();
set from t threads=2;
summation = summation + partial_sum;
end;
method term();
put summation=;
end;
enddata;
run;
quit;
```

Instead of an ERROR message pair, when you define your error message text in the SETTHREADERRORSTATUS function, a single ERROR message is written to the log for each row that meets the custom error condition.

```
… [ snip] ...
summation=49950000
NOTE: Created thread processdataset in data set work.processdataset.
ERROR: Line 113: Null value in row 1000 thread 1
ERROR: Line 113: Null value in row 808 thread 2
ERROR: Line 113: Null value in row 2000 thread 1

ERROR: Line 113: Null value in row 8000 thread 1
```

SHA256 Function

Returns the result of the message digest of a specified string.

Category: Character

Returned data type: BINARY

Syntax

SHA256('*string*')

Required Argument

string
specifies a character constant, variable, or expression.

Data type: BINARY, CHAR

Tips: Enclose a literal string of characters in single quotation marks.

For scalar character variable arguments, the initial character set encoding that is specified in the DECLARE statement is used to transcode the variable before it is passed to the SHA256 function. For binary arguments, the binary value is treated as a character string and the session encoding is used to transcode the value before it is passed to the SHA256 function.

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The SHA256 function converts a message string, based on the SHA256 algorithm, to a 256-bit hash value.

The SHA256 function does not format its own output. Use the $BINARY*w*. or $HEX*w*. format to view readable results.

You can use the SHA256 function to track changes in your data sets. The SHA256 function can generate a digest of a set of column values in a table record. This digest could be treated as the signature of the record and be used to track changes that are made to the record. If the digest from the new record matches the existing digest of a table record, then the two records are the same. If the digest is different, then a column value in the record has changed. The new changed record could then be added to the table along with a new surrogate key because the record represents a change to an existing keyed value.

The SHA256 function can be useful when you are developing shell scripts for software installation, file comparison, and detection of file corruption and tampering.

Example: Generating Results with the SHA256 Function

This program generates results that are returned by the SHA256 function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl binary(64) y z;
   method init();
      y=sha256('abc');
      z=sha256('access method');
      put y=$HEX64.;
      put z=$HEX64.;
    end;
enddata;
run;
quit;
```

For ASCII systems, SAS writes the following output to the log:

```
y=BA7816BF8F01CFEA414140DE5DAE2223B00361A396177A9CB410FF61F20015AD
z=F2758E91725621F59F2F80D15DE8824560EDC471EBE40A83BA6D1259B1605915
```

SHA256HEX Function

Returns the result of the message digest of a specified string and converts the string to hexadecimal representation.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Notes: The SHA256HEX function verifies the data integrity and authentication of a message.

UTF-8 text is recommended for the SHA256HEX function arguments to ensure consistency across encodings.

Syntax

SHA256HEX('*string*', *string_indicator*);

Required Arguments

string

specifies any valid expression that evaluates or can be coerced to a character string.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

string_indicator

indicates whether the argument *string* is regular characters or hexadecimal representation characters. A 0 indicates that the expression in the argument *string* is regular characters. indicates that the expression in the argument *string* is hexadecimal representation characters.

indicates whether the argument *string* is regular characters or hexadecimal representation characters.

0

indicates that the expression in the argument *string* is regular characters.

1

indicates that the expression in the argument *string* is hexadecimal representation characters.

Note: There must be an even number of hexadecimal representation characters, and they must all be between 0–9, a–f, A–F. Blanks in the hexadecimal representation string are ignored.

Data type DOUBLE

Details

The Basics

The SHA256HEX function converts a string, based on the SHA256 algorithm, to a 256-bit hash value. Then, the function converts the data to a hexadecimal representation format.

Using the SHA256HEX Function

You can use the SHA256HEX function to track changes in your data sets. The SHA256HEX function can generate a digest of a set of column values in a table record. This digest could be treated as the signature of the record and be used to track changes that are made to the record. If the digest from the new record matches the existing digest of a table record, then the two records are the same. If the digest is different, then a column value in the record has changed. The new changed record could then be added to the table along with a new surrogate key because the record represents a change to an existing keyed value.

The SHA256HEX function can be useful when you are developing shell scripts or Perl programs for software installation, file comparison, and detection of file corruption and tampering.

Comparisons

The SHA256 function does not format its own output, so you must use the $BINARYw. or $HEXw. formats to view readable results. The SHA256HEX function formats its output, so you do not have to use the $BINARY or $HEX formats.

Example: Generating Results with the SHA256HEX Function

This example generates results that are returned by the SHA256HEX function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(64) y z;
   method run();
      y=sha256hex('abc');
      z=sha256hex('access method');
```

```
        put y=;
        put z=;
    end;
enddata;
run;
quit;
```

For ASCII systems, SAS writes the following output to the log:

```
y=BA7816BF8F01CFEA414140DE5DAE2223B00361A396177A9CB410FF61F20015AD
z=F2758E91725621F59F2F80D15DE8824560EDC471EBE40A83BA6D1259B1605915
```

See Also

Functions:

- "SHA256HMACHEX Function" on page 1148

SHA256HMACHEX Function

Returns the result of the message digest of a specified string by using the Hash-based Message Authentication (HMAC) algorithm.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Notes: The SHA256HMACHEX function verifies the data integrity and authentication of a message.

See the following article for more information about the Hash-based message authentication code (HMAC).

UTF-8 text is recommended for the SHA256HMACHEX function arguments to ensure consistency across encodings.

Syntax

SHA256HMACHEX('*key*', '*message*' [*string-indicator*]);

Required Arguments

key

specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

message
specifies a secret key padded to the right with extra zeros to the input block size of the hash function.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Optional Argument

string_indicator
indicates whether the key and message are provided in hexadecimal representation. A 0 indicates that the arguments *key* and *message* are not represented in hexadecimal representation. A 1 indicates that the argument *message* is represented in hexadecimal representation. A 2 indicates that the argument *key* is represented in hexadecimal representation. A 3 indicates that the arguments *key* and *message* are represented in hexadecimal representation.

indicates whether the key and message are provided in hexadecimal representation.

0
the arguments *key* and *message* are not represented in hexadecimal representation.

1
the argument *message* is represented in hexadecimal representation.

2
the argument *key* is represented in hexadecimal representation.

3
the arguments *key* and *message* are represented in hexadecimal representation.

Note: This argument is useful when the SHA256HMACHEX function is being called repeatedly and the result of a previous call is used as the key in a subsequent call. The following code demonstrates this functionality:

```
length digest $64;
digest = sha256hmachex('mykey', 'mymessage', 0);
digest = sha256hmachex(digest, 'my new message', 2);
```

Data type DOUBLE

Details

The SHA256HMACHEX function converts a string, based on the SHA256 algorithm, to a 256-bit hash value.

See the following article for more information about the Hash-based message authentication code (HMAC).

Example: Generating Results with the SHA256HMACHEX Function

This example generates results that are returned by the SHA256HMACHEX function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(200) digest;
   method run();
      digest = SHA256HMACHEX('key',
      'The quick brown fox jumps over the lazy dog', 0);
      if digest=

upcase('f7bc83f430538424b13298e6aa6fb143ef4d59a14946175997479dbc2d1a3cd
8')
         then
            put 'matched';
         else
            put 'not matched';
   end;
enddata;
run;
quit;
```

```
matched
```

SIGN Function

Returns a number that indicates the sign of a numeric value expression.

Category: Mathematical

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

SIGN(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type All numeric types

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The SIGN function returns the following values:

-1
if *expression* < 0

0
if *expression* = 0

1
if *expression* > 0.

Example

The following program illustrates the SIGN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y z;
   method run();
      x=sign(-5);
      y=sign(5);
      z=sign(0);
      put x= y= z=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=-1 y=1 z=0
```

SIN Function

Returns the trigonometric sine.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

SIN(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the SIN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y z;
   method run();
      x=sin(0.5);
      y=sin(0);
      z=sin(3.14159/4);
   put x= y= z=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0.4794255386042 y=0 z=0.70710631209355
```

SINH Function

Returns the hyperbolic sine.

Category: Hyperbolic

Returned data type: DOUBLE

Syntax

SINH(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The SINH function returns the hyperbolic sine of the argument, which is given by the following equation.

$$e^{argument} - e^{-argument}/2$$

Example

The following program illustrates the SINH function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x y z;
   method run();
      x=sinh(0);
      y=sinh(1);
      z=sinh(-1);
      put x= y= z=;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0 y=1.1752011936438 z=-1.1752011936438
```

SKEWNESS Function

Returns the skewness.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

SKEWNESS(*expression-1, expression-2, expression-3* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least three non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

Data type: DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If all non-null or nonmissing arguments have equal values, the skewness is mathematically undefined and the SKEWNESS function returns a null or missing value.

Example

The following program illustrates the SKEWNESS function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x1 x2 x3 x4;
   method run();
      x1=skewness(0, 1, 1);
      x2=skewness(2, 4, 6, 3, 1);
      x3=skewness(2, 0, 0);
      x4=skewness(of x1-x3);
      put x1=;
      put x2=;
      put x3=;
      put x4=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=-1.73205080756887
x2=0.59012865638436
x3=1.73205080756887
x4=-0.9530977136649
```

SLEEP Function

For a specified period of time, suspends the execution of a program that invokes this function.

Category: Special

Returned data type: DOUBLE

Syntax

SLEEP(*number-of-time-units* [, *time-unit*])

Required Argument

number-of-time-units
specifies any valid expression that evaluates to a numeric value and that specifies the number of units of time for which you want to suspend execution of a program.

Range $n \geq 0$

Restriction Negative values are invalid.

Data type DOUBLE

Tip If you use a fraction for the *n* argument, the *unit* argument is required if you want to suspend execution for a fraction of a second. For example, `SLEEP(.25);` does not suspend execution. `SLEEP(1.25);` suspends execution for 1 second. `SLEEP(1.25, 1);` suspends execution for 1.25 seconds. `SLEEP(.25,1)` suspends execution for .25 seconds.

Optional Argument

time-unit
specifies that the unit of time in seconds is a multiple of 10, and that is applied to *number-of-time-units*. For example, 1 corresponds to 1 second, and .001 to a millisecond, and 5 corresponds to 5 seconds.

Default .001

Data type DOUBLE

Example This code suspends execution of the program for 10 seconds:

```
x=sleep(10,1);
```

Details

The SLEEP function suspends the execution of a program that invokes this function for a period of time that you specify.

The SLEEP function suspends the execution of a program and returns the value of the first argument.

If you are using a GUI environment such as SAS Data and AI Studio (known as SAS Studio prior to 2026.06), then the SLEEP function uses the default *time-unit* value. A window appears that indicates how long SAS is going to sleep.

When you submit a program that calls the SLEEP function, the SLEEP window appears, telling you when SAS is going to wake up. Your SAS session remains inactive until the sleep period is over. To cancel the call to the SLEEP function, use the CTRL+BREAK attention sequence.

You should use a null data program to call the SLEEP function; follow this data program with the rest of the SAS program. Using theSLEEP function in this manner enables you to use the CTRL+BREAK attention sequence to interrupt the SLEEP function and to continue with the execution of the rest of your SAS program.

Examples

Example 1: Suspending Execution for a Specified Period of Time

The following program delays the execution for 20 seconds:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data payroll;
   method init();
   time_slept=sleep(20,1);
  /*...more DS2 statements...*/
   end;
enddata;
run;
quit;
```

Example 2: Suspending Execution Based on a Calculation of Sleep Time

The following program tells SAS to suspend the execution until June 15, 2011, at midnight. DS2 calculates the length of the suspension based on the target date and the date and time that the code begins to execute.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data budget;
   method init();
   sleeptime= dhms(mdy(06,15,2011),00,00,02) -
dhms(mdy(06,15,2011),00,00,00);
   time_calc=sleep(sleeptime,1);
   /*...more DS2 statements...*/
   end;
enddata;
run;
quit;
```

SMALLEST Function

Returns the *k*th smallest non-null or nonmissing value.

Category:	Descriptive Statistics
Returned data type:	DOUBLE
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is

set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

SMALLEST(*k*, *expression* [, ...*expression*])

Required Arguments

k

specifies any valid expression that evaluates to a numeric value to return.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression

specifies any valid expression that evaluates to a numeric value to be processed.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

If *k* is null or missing, less than zero, or greater than the number of values, the result is a null or missing value.

Comparisons

The SMALLEST function differs from the ORDINAL function in that SMALLEST ignores null and missing values, but ORDINAL counts null and missing values.

Example

This example compares the values that are returned by the SMALLEST function with values that are returned by the ORDINAL function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data comparison;
   dcl double smallest_num having label 'SMALLEST Function';
```

```
   dcl double ordinal_num having label 'ORDINAL Function';
   dcl double k;
   method run();
      do k = 1 to 4;
         smallest_num = smallest(k, 456, 789, .Q, 123);
         ordinal_num  = ordinal (k, 456, 789, .Q, 123);
         output;
      end;
   end;
enddata;
run;
quit;
proc print data=comparison label;
   var k smallest_num ordinal_num;
   title 'Results From the SMALLEST and the ORDINAL Functions';
run;
```

Output 7.28 *Comparison of Values: The SMALLEST and the ORDINAL Functions*

Results From the SMALLEST and the ORDINAL Functions

Obs	K	SMALLEST Function	ORDINAL Function
1	1	123	Q
2	2	456	123
3	3	789	456
4	4	.	789

- “PCTL Function” on page 927

SQLEXEC Function

Executes a FedSQL statement to create, delete, or update a table or to insert rows into a table.

Category: Special

Restriction: This function is not supported on the CAS server.

Syntax

SQLEXEC('*sql-text*')

Required Argument

'sql-text'
is a valid FedSQL statement that inserts into, updates, creates, or deletes rows from a table.

CAUTION
Only FedSQL statements can be used with the SQLEXEC function. DBMS-specific SQL cannot be used. For more information, see *SAS FedSQL Language Reference*.

Requirement: The FedSQL statement must be enclosed in single quotation marks (').

Note: The statement can be a string literal, a string value generated from an expression, or a string value that is stored in a variable.

Details

The following items apply to the SQLEXEC function:

- Use the SQLEXEC function when a FedSQL statement is to be executed only once.
- Allocate, prepare, execute, and free are performed at run time.
- The SQLEXEC function does not support parameters.
- The SQLEXEC function does not support the return of a result set. It cannot be used with a SELECT statement.
- SQLEXEC is similar to the SQL EXECUTE IMMEDIATE statement or the JDBC Statement.executeUpdate (*string*) method.

An SQLSTMT package enables you to execute a FedSQL statement more than one time, to use parameters, and to access a result set. For more information, see "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*.

Example: Use SQLEXEC Function to Create an Empty Table

The following program creates five tables. Each table has three columns and no rows.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   declare int i;
   declare int rc;
   method init();
      do i = 1 to 5;
       rc = sqlexec('create table testdata' || i ||
          '(x double, y double, z double)');
       if (rc ne 0) then put 'TEST FAILED';
   end;
end;
enddata;
run;
quit;
```

See Also

"Comparing the SQLSTMT Package and the SQLEXEC Function" in *SAS DS2 Programmer's Guide*

SQRT Function

Returns the square root of a value.

Category: Mathematical

Returned data type: DOUBLE

Syntax

SQRT(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a nonnegative numeric value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the SQRT function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double a b c;
   method run();
      a=sqrt(36);
      b=sqrt(25);
      c=sqrt(4.4);
      put a=;
      put b=;
      put c=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=6
b=5
c=2.0976176963403
```

SQUANTILE Function

Returns the quantile from a distribution when you specify the right probability (SDF).

Category: Quantile

Returned data type: DOUBLE

See: "SDF Function" on page 1133

Syntax

SQUANTILE(*'distribution'*, *probability*, *parameter-1, ..., parameter-k*)

Required Arguments

distribution
is a character constant, variable, or expression that identifies the distribution.

Note: The arguments for each of the SQUANTILE Distribution functions are identical to those of the corresponding CDF Distribution functions.

Here are valid distributions:

Distribution	Argument
Bernoulli	'BERNOULLI'
Beta	'BETA'
Binomial	'BINOMIAL'
Cauchy	'CAUCHY'
Chi-Square	'CHISQUARE'
Conway-Maxwell-Poisson	'CONMAXPOI'
Exponential	'EXPONENTIAL'
F	'F'
Gamma	'GAMMA'
Generalized Poisson	'GENPOISSON'
Geometric	'GEOMETRIC'
Hypergeometric	'HYPERGEOMETRIC'
Laplace	'LAPLACE'
Logistic	'LOGISTIC'
Lognormal	'LOGNORMAL'
Negative binomial	'NEGBINOMIAL'
Normal	'NORMAL' | 'GAUSS'
Normal mixture	'NORMALMIX'
Pareto	'PARETO'

Distribution	Argument
Poisson	'POISSON'
T	'T'
Tweedie	'TWEEDIE'
Uniform	'UNIFORM'
Wald (inverse Gaussian)	'WALD' | 'IGAUSS'
Weibull	'WEIBULL'

Note: Except for T, F, and NORMALMIX, you can minimally identify any distribution by its first four characters.

probability
is a numeric constant, variable, or expression that specifies the value of a random variable.

Data type DOUBLE

parameter-1, ..., parameter-k
are optional *shape*, *location*, or *scale* parameters that are appropriate for the specific distribution.

Data type DOUBLE

Details

The SQUANTILE function computes the quantile from the specified continuous or discrete distribution, based on the probability value that is provided. For more information, see the individual distributions noted in the table above.

The Conway-Maxwell-Poisson distribution of the SQUANTILE function returns the counts value *y* that is the smallest, whole number whose SDF value is less than *p*. The syntax for the Conway-Maxwell-Poisson distribution in the SQUANTILE function has the following form:

SQUANTILE('CONMAXPOI', *p*, *λ*, *v*)

p
is a real number between 0 and 1, inclusively.

λ
is similar to the mean, as in the Poisson distribution.

v
is a dispersion parameter.

For more information, see "Conway-Maxwell-Poisson" distribution in the PDF function on page 941.

Examples

Example 1: Using the LOGISTIC Distribution

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double p sdf;
   dcl varchar(10) dist;
   method init();
      dist='logistic';
      sdf=squantile(dist, 1.e-20);
      put sdf=;
      p=sdf(dist, sdf);
      put p= /* p will be 1.e-20 */;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
sdf=46.0517018598809
p=1E-20
```

Example 2: Using the Conway-Maxwell-Poisson Distribution

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double y;
   method init();
      y=squantile('conmaxpoi',.2,2.3,.4);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
y=12
```

STD Function

Returns the standard deviation.

Category: Descriptive Statistics

Returned data type: DOUBLE

Syntax

STD(*expression-1, expression-2* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement: At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.

Data type: DOUBLE

See: “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the STD function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double val1 val2 val3 val4;
   method run();
      val1=2;
      val2=4;
      val3=6;
      val4=8;
      output;
   end;
enddata;
run;

data test2(overwrite=yes);
   dcl double x1 x2 x3 x4;
   method init();
      set test;
      x1=std(val1,val3);
      x2=std(val1,val3, .);
      x3=std(val1,val2,val3, 3, 1);
      x4=std(of x1-x3);
      put x1= x2= x3= x4=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=2.82842712474619 x2=2.82842712474619 x3=1.92353840616713 x4=0.52243774525827
```

STDERR Function

Returns the standard error of the mean.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

STDERR(*expression-1, expression-2* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement	At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.
Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the STDERR function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double val1 val2 val3 val4;
   method run();
      val1=2;
      val2=4;
      val3=6;
      val4=8;
      output;
   end;
enddata;
run;

data test2(overwrite=yes);
   dcl double x1 x2 x3 x4;
   method init();
      set test;
      x1=stderr(val1,val3);
      x2=stderr(val1,val3, .);
      x3=stderr(val1,val2,val3, 3, 1);
      x4=stderr(of x1-x3);
      put x1=;
      put x2=;
      put x3=;
      put x4=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=2
x2=2
x3=0.86023252670426
x4=0.37992249109857
```

STFIPS Function

Converts state postal codes to FIPS state codes.

Category: State and ZIP code

Restriction: This function is not supported on the CAS server.

Returned data type: DOUBLE

Syntax

STFIPS(*postal-code*)

Required Argument

postal-code
specifies a character expression that contains the two-character standard state postal code. Characters can be mixed case. The function ignores trailing blanks, but generates an error if the expression contains leading blanks.

Data type CHAR()

Details

The STFIPS function converts a two-character state postal code (or worldwide GSA geographic code for U.S. territories) to the corresponding numeric U.S. Federal Information Processing Standards (FIPS) code.

Comparisons

The STFIPS, STNAME, and STNAMEL functions take the same argument but return different values. STFIPS returns a numeric U.S. Federal Information Processing Standards (FIPS) code. STNAME returns an uppercase state name. STNAMEL returns a mixed-case state name.

Example

The following example shows the difference when using STFIPS, STNAME, and STNAMEL on the two-digit postal code for the state of North Carolina:

```
proc ds2;
 data _null_;
   method run();
   dcl double fips;
   dcl char(15) state;
   fips=stfips('NC');
   put fips=;
   state=stname('NC');
   put state=;
   state=stnamel('NC');
   put state=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
fips=37
state=NORTH CAROLINA
state=North Carolina
```

- “STNAMEL Function” on page 1172

STNAME Function

Converts state postal codes to uppercase state names.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR

Syntax

STNAME(*postal-code*)

Required Argument

postal-code
specifies a character expression that contains the two-character standard state postal code. Characters can be mixed case. The function ignores trailing blanks, but generates an error if the expression contains leading blanks.

Details

The STNAME function converts a two-character state postal code (or worldwide GSA geographic code for U.S. territories) to the corresponding state name in uppercase.

Comparisons

The STNAME and STNAMEL functions both take a two-digit postal code as an argument and return a state name. STNAME returns an uppercase state name. STNAMEL returns a mixed-case state name.

Example

This example converts the two-digit postal code for the state of North Carolina to an uppercase state name.

```
proc ds2;
 data _null_;
   method run();
   dcl char(15) state;
   state=stname('NC');
   put state=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
state=NORTH CAROLINA
```

- “FIPNAME Function” on page 654
- “FIPNAMEL Function” on page 656
- “FIPSTATE Function” on page 658
- “STNAMEL Function” on page 1172

STNAMEL Function

Converts state postal codes to mixed case state names.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR

Syntax

STNAMEL(*postal-code*)

Required Argument

postal-code
specifies a character expression that contains the two-character standard state postal code. Characters can be mixed case. The function ignores trailing blanks, but generates an error if the expression contains leading blanks.

Details

If the STNAMEL function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

The STNAMEL function converts a two-character state postal code (or worldwide GSA geographic code for U.S. territories) to the corresponding state name in mixed case.

Example

This example converts the two-digit postal code for the state of North Carolina to a mixed-case state name.

```
proc ds2;
 data _null_;
   method run();
   dcl char(15) state;
   state=stnamel('NC');
   put state=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
state=North Carolina
```

STREAMINIT Function

Specifies a random-number generator and seed value for generating random numbers.

Category:	Random Number
Returned data type:	DOUBLE
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

Form 1: **STREAMINIT**([*seed*])

Form 2: **STREAMINIT**([*RNG*]

Form 3: **STREAMINIT**([*RNG*, *seed*]

Optional Arguments

seed

a numeric expression that specifies the value used to initialize a stream of pseudorandom numbers.

Range The range of seed values depends on the RNG.

Data type DOUBLE

Note For each thread, all the streams are initialized by using the seed value in the first call to the STREAMINIT function. Subsequent calls to the STREAMINIT function from the same thread are ignored.

RNG

a character expression that specifies the random-number generator (RNG) for generating random or pseudorandom numbers in subsequent calls to the RAND function. The character expression is not case sensitive.

The following generators are supported:

RNG	Description
MTHybrid	Hybrid 1998/2002 32-bit Mersenne twister. Default method.
MT1998	1998 32-bit Mersenne twister. Deprecated.
MT32 | MT2002	2002 32-bit Mersenne twister.
MT64	64-bit Mersenne twister.
PCG | PCG64i	64-bit permuted congruential generator.
TF2 | THREEFRY2x64	Threefry 2x64-bit counter-based RNG based on the Threefish encryption function in the Random123 library.
TF4 | THREEFRY4x64	Threefry 4x64-bit counter-based RNG based on the Threefry method in the Random123 library.
HARDWARE	Any supported hardware-based random number generator.

RNG	Description
RDRAND	Intel hardware-based RdRand instructions.

For more information about random-number generators, see "Using Random-Number Functions and CALL Routines in the DATA Step" in *SAS Functions and CALL Routines: Reference*.

Restriction The HARDWARE RNG is available only on Intel processors that support the RdRand instruction: Ivy Bridge and later processors.

Tips For each thread, all the streams are initialized by using the seed value in the first call to the STREAMINIT function. Subsequent calls to the STREAMINIT function from the same thread are ignored.

If you do not specify an *RNG*, the RAND function uses the MTHYBRID RNG to compute streams of (pseudo) random numbers.

The PCG RNG provides a good combination of statistical quality, speed, cycle length, and multiple independent streams.

Details

Basics

A sequence of random or pseudorandom values that are generated by an *RNG* is called a *stream*. The STREAMINIT function uses a positive seed to initialize an *RNG*. Within each thread, the first call to the STREAMINIT function initializes the *RNG*; subsequent calls in the same thread do not reinitialize the stream. The *RNG* remains in effect in each thread for the remainder of the DS2 program.

An *RNG* generates random values from the uniform distribution. The RAND function uses one or more uniform variates from the *RNG* to construct a value from a probability distribution. Each call to the RAND function uses at least one value from the stream. The call updates the internal state of the *RNG*.

To generate a reproducible stream of pseudorandom values, call the STREAMINIT function with a positive seed value and specify any of the pseudorandom *RNG*s. If the STREAMINIT function is called before the RAND function, the resulting stream of random numbers is reproducible. Every time you run the DS2 program, it generates the same stream.

If you specify a hardware-based *RNG*, seed values are ignored. Random numbers from a hardware *RNG* are not reproducible. If you run a SAS program that uses a hardware *RNG* multiple times, you get different random numbers every time you run the program.

SAS computes a default seed value if you use a pseudorandom generator and call any of these routines or function:

- Call the STREAMINIT function with a missing zero or negative *seed* argument.

- Call the STREAMINIT function without the *seed* argument.
- Call the RAND function without previously calling the STREAMINIT function.

If the STREAMINIT function initializes the stream or streams, it returns the value of the seed. If the stream or streams have already been initialized by calling the STREAMINIT function or the RAND function, then the STREAMINIT function returns 0.

When called from a DS2 program, the following FCMP functions do not recognize seed values that are set in the DS2 program.

COMPCOST
COMPGED
RAND
STREAMINIT

In a DATA step, all random numbers from RAND are drawn from the same stream by default, but you can create multiple independent streams by using the CALL STREAM routine.

In PROC DS2, random numbers from RAND that are called inside an FCMP package come from a separate stream. To get reproducible random numbers, use the CALL STREAMINIT routine inside each FCMP function that calls RAND. To get independent streams, also use the CALL STREAM routine inside each FCMP function that calls RAND. If you do so, the results from DS2 are consistent with a DATA step. For an example, see "Considerations and Limitations When Using the FCMP Package" in *SAS DS2 Programmer's Guide*.

Range of *seed* Values

For MTHybrid, MT32, and MT1998, the seed value can be an integer from 1 to $2^{32}-1=4294967295$.

For MT64, PCG, Threefry2x64, and Threefry4x64, the seed value can be an integer from 1 to $2^{64}-1025=18446744073709549568$. Some large integers do not have an exact representation in double-precision floating-point numbers.

If the seed argument is missing or less than or equal to zero, SAS generates a seed value as described in "Using Random-Number Functions and CALL Routines in the DATA Step" in *SAS Functions and CALL Routines: Reference*.

If a positive seed value is out of range, the mantissa of the seed argument is scaled to an integer that is within range.

Examples

Example 1: Specify a Seed Value to Create a Reproducible Stream of Pseudorandom Numbers with the RAND Function

The following program illustrates how to specify a seed value with the STREAMINIT function to create a reproducible stream of pseudorandom numbers with the RAND function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data random (overwrite=yes);
   dcl double i x1;
   method run();
      streaminit(123);
      do i=1 to 10;
         x1=rand('cauchy');
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=random;
   id i;
run;
quit;
```

Output 7.29 *Number String Seeded with the STREAMINIT Function*

The SAS System

i	x1

8	7.61304
9	0.89784
10	1.69348

Example 2: Use the 64-bit Mersenne Twister Random-Number Generator

The following program illustrates how to specify a seed value with the MT64 RNG to create a stream of pseudorandom numbers with the RAND function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data random (overwrite=yes drop=(MT64));
```

```
   dcl double i x1;
   method run();
      streaminit('MT64', 123);
      do i=1 to 10;
         x1=rand('cauchy');
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=random;
   id i;
run;
quit;
```

Output 7.30 *Number String Seeded with the MT64 Random-Number Generator*

The SAS System

10	-0.5185

Example 3: Specify a Seed and Use the 64-bit Mersenne Twister Random-Number Generator

The following program shows a seed value with the MT64 RNG to create a stream of pseudorandom numbers with the RAND function.

Note: In this example, code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data random (overwrite=yes drop=(MT64));
   dcl double i x1;
   method run();
      streaminit('MT64', 128645);
      do i=1 to 10;
         x1=rand('cauchy');
```

```
            output;
         end;
      end;
   enddata;
   run;
   quit;

   proc print data=random;
      id i;
   run;
   quit;
```

Output 7.31 *Number String with the Seed Number and the 64-bit Mersenne Twister Random-Number Generator*

Functions:

- "RAND Function" on page 1071

STRIP Function

Returns a character string with all leading and trailing blanks removed.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

STRIP(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The STRIP function returns the argument with all leading and trailing blanks removed. If the argument is blank, STRIP returns a string with a length of zero.

If the value that is trimmed is shorter than the length of the receiving variable, SAS pads the value with new trailing blanks.

Note: The STRIP function is useful for concatenation because the concatenation operator does not remove trailing blanks.

Comparisons

The following list compares the STRIP function with the TRIM function:

- For blank character strings, the STRIP and TRIM functions both return a string with a length of zero.
- For strings that lack leading blanks, the STRIP and TRIM functions return the same value.

Example

The following program shows the results of using the STRIP function to delete leading and trailing blanks.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data lengthn (overwrite=yes);
   dcl char(8) string;
```

```
   method init();
      string='abcd    '; output;
      string='  abcd  '; output;
      string='    abcd'; output;
      string='abcdefgh'; output;
      string='x y x'; output;
   end;
enddata;
run;

data stripstring (overwrite=yes);
   dcl varchar(10) original;
   dcl varchar(10)  stripped;
   method run();
      set lengthn;
      original = '*' || string || '*';
      stripped = '*' || strip(string) || '*';
   end;
enddata;
run;
quit;

proc print data=stripstring;
run;
```

Output 7.32 *Results from the STRIP Function*

The SAS System

Obs	ORIGINAL	STRIPPED	STRING
1	*abcd *	*abcd*	abcd
2	* abcd *	*abcd*	abcd
3	* abcd*	*abcd*	abcd
4	*abcdefgh*	*abcdefgh*	abcdefgh
5	*x y x *	*x y x*	x y x

SUBSTR (left of =) Function

Replaces content in a character variable.

Category: Character

Syntax

SUBSTR (*character-variable*, *position-expression* [, *length-expression*]) = *characters-to-replace*

Required Arguments

character-variable
specifies a character variable.

Restriction *character-variable* must be a variable or an array reference. It cannot be an expression or a literal.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

position-expression
specifies the character position of the first character of content in the *character-variable* that is to be replaced.

Requirement *position-expression* must be greater than or equal to 1.

Data type BIGINT. Other types are coerced to BIGINIT.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

characters-to-replace
specifies a character constant, variable, or expression that replaces the contents of *character-variable*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note Enclose a literal string of characters in quotation marks.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

length-expression
specifies the length of the substring that is replaced.

Restriction	*length-expression* cannot be larger than the length of the expression that remains in *character-variable* after *position-expression*.
Data type	BIGINT. Other types are coerced to BIGINIT.
Notes	If you omit *length-expression*, SAS uses all of the characters on the right side of the assignment statement to replace the values of *character-variable*. *length-expression* can be larger than the actual length of *characters-to-replace*.
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

Note: In the following discussion, length refers to character-based length as opposed to byte-based length.

When you use the SUBSTR function on the left side of an assignment statement, SAS replaces a substring of the content in *character-variable* with the character string value on the right side of the equal (=) sign.

SUBSTR starts the replacement at the character position that you specify in *position-expression*. SUBSTR inserts the number of characters specified in *length-expression* from the replacement into *character-variable*.

The SUBSTR (left of) function returns a WARNING message and does not modify *character-variable* if any of the following are true:

- *position-expression* is a missing value, null value, less than zero, or larger than the length of the substring in *character-variable*.
- *length-expression* is a missing value, null value, less than zero, or larger than the length of the substring in *character-variable* .
- the length of the resulting character string after *length-expression* and *position-expression* are applied to *character-variable* is longer than the declared length of *character-variable*.

If the length of *characters-to-replace* is longer than *length-expression*, the string is truncated to *length-expression* before being used as the substring replacement in *character-variable*. If the length of *characters-to-replace* is shorter than *length-expression*, *characters-to-replace* is blank padded to *length-expression* characters before being used as the substring replacement in *character-variable*.

Use of the SUBSTR (left of) function with undeclared character variables can lead to unexpected results.

Example

The following programs illustrate the SUBSTR (left of=) function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/*** replaces 3 characters starting at position 1 ***/
proc ds2;
data test (overwrite=yes);
   dcl char mystring;
   method run();
      mystring='kidnap';
      substr(mystring, 1, 3)='cat';
      put mystring=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
mystring=catnap
```

```
/*** When position 1 is specified ***/
/***  and length is omitted, all characters  ***/
/***  are replaced with characters-to-replace ***/
proc ds2;
data test (overwrite=yes);
   dcl char mystring;
   method run();
      mystring='kidnap';
      substr(mystring, 1)='cat';
      put mystring=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
mystring=cat
```

```
/*** When character-variable is undeclared, ***/
/*** length is ommitted, and position is 1, all characters ***/
/***  are replaced with the first letter of characters-to-replace. ***/
proc ds2;
data test (overwrite=yes);
   method run();
      mystring=' ';
      substr(mystring, 1)='cat';
      put mystring=;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
c
WARNING: Line 83: No DECLARE for assigned-to variable mystring; creating it as a
global variable of type char(1).
```

```
/*** When position is a missing value,***/
/*** nothing is replaced ***/
proc ds2;
data test (overwrite=yes);
   dcl char mystring;
   method run();
      mystring='kidnap';
      substr(mystring,.)='cat';
      put mystring=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
mystring=kidnap
WARNING: Line 85: Argument 2 to function SUBSTR is invalid.
```

```
/*** characters-to-replace can be appended ***/
/*** to character-variable as long as the resulting ***/
/*** string does not exceed the variable's declared length ***/
proc ds2;
data test (overwrite=yes);
   dcl varchar(10) mystring;
   method run();
      mystring='cat';
      substr(mystring, 4, 3)='napper';
      put mystring=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
catnap
```

Functions:

- “SUBSTR (right of =) Function” on page 1186
- “SUBSTRN Function” on page 1189

SUBSTR (right of =) Function

Extracts a substring from an argument.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

SUBSTR(*character-expression*, *position-expression* [, *length-expression*])

Required Arguments

character-expression
specifies a character constant, variable, or expression.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

position-expression
specifies a numeric constant, variable, or expression that is the beginning character position.

Requirement *position-expression* must be greater than or equal to zero.

Data type BIGINT

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

length-expression
specifies a numeric constant, variable, or expression that is the length of the substring to extract.

Interaction If you omit *length-expression*, the SUBSTR function extracts the remainder of the expression. When *length-expression* is zero, a negative value, or larger than the length of the expression that remains in string after position, the function extracts the remainder of the expression. The function also prints a WARNING to the log indicating that the argument is invalid.

Data type BIGINT

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The SUBSTR function extracts a portion of an expression that you specify in *character-expression*. The portion begins with the character position that you specify in *position-expression*, and is the number of characters that you specify in *length-expression*.

Comparisons

Use the SUBSTR function when you want substring extraction behavior that is similar to that of the DATA step. Note that when an input expression is invalid, the DATA step sets _ERROR_ to 1 and prints a note to the log. DS2 returns a WARNING and prints a note to the log.

Example

The following programs illustrate the SUBSTR (right of =) function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/**** selects all chars starting at position 5 to the end of the
string ****/
proc ds2;
data test (overwrite=yes);
   dcl char(12) a b;
   method run();
      a='chsh234960b3';
      b=substr(a,5);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
234960b3
```

```
/**** selects 6 chars starting at position 5 ****/
proc ds2;
data test (overwrite=yes);
   dcl char(12) a b;
   method run();
      a='chsh234960b3';
      b=substr(a,5, 6);
      put b;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
234960
```

```
/**** selects all chars starting at position 5 to the end of the
string ****/
/**** because of the invalid third argument ****/
proc ds2;
data test (overwrite=yes);
   dcl char(12) a b;
   method run();
      a='chsh234960b3';
      b=substr(a, 5, 15);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
234960b3
WARNING: Line 351: Argument 3 to function SUBSTR is invalid.
```

```
/**** selects all chars starting at position 5 to the end of the
string ****/
/**** because of the invalid third argument ****/
proc ds2;
data test (overwrite=yes);
   dcl char(12) a b;
   method run();
      a='chsh234960b3';
      b=substr(a, 5, -5);
      put b;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
234960b3
WARNING: Line 362: Argument 3 to function SUBSTR is invalid.
```

See Also

Functions:

- “SUBSTR (left of =) Function” on page 1182
- “SUBSTRN Function” on page 1189

SUBSTRN Function

Returns a substring, allowing a result with a length of zero.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

SUBSTRN(*expression*, *position-expression*[, *length-expression*])

Required Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string or numeric value.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR, DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

position-expression
specifies any valid expression that evaluates to a BIGINT and that specifies the position of the first character in the substring.

Data type BIGINT

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

length-expression
specifies any valid expression that evaluates to a BIGINT and that specifies the length of the substring.

Data type BIGINT

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The Basics

The following information applies to the SUBSTRN function:

- The SUBSTRN function returns the substring from *position-expression* to the end of the *character-expression* if *length-expression* meets either of the following conditions:
  - is not specified
  - is greater than the length of the substring from *position-expression* to the end of the *expression*
- The SUBSTRN function returns a missing (SAS mode) or null value (ANSI mode) with a length of zero if any of the following conditions are true:
  - *position-expression* is a missing (SAS mode) or null value (ANSI mode)
  - *length-expression* is a missing (SAS mode) or null value (ANSI mode)

  Note: In addition, an error is written to the log stating that the argument is invalid.
- The SUBSTRN function returns a missing value (SAS mode) or an empty string (ANSI mode) with a length of zero if any of the following conditions are true:
  - *expression* is a missing (SAS mode) or null value (ANSI mode)
  - *length-expression* is less than 1
  - *position-expression* is less than 1 or greater than the length of *character-expression*

Comparisons

The following table lists comparisons between the SUBSTRN and the SUBSTR functions:

Condition	Function	Result
the value of *position-expression* is nonpositive	SUBSTRN	returns a missing value (SAS mode) or empty string (ANSI mode) of length 0
the value of *position-expression* is nonpositive	SUBSTR	returns a missing (SAS mode) or null value (ANSI mode) of length 0

Condition	Function	Result
the value of *length-expression* is nonpositive	SUBSTRN	returns a missing value (SAS mode) or empty string (ANSI mode) of length 0
the value of *length-expression* is nonpositive	SUBSTR	returns the substring from *position-expression* to the end of the *character-expression*
the value of the *length-expression* is a missing (SAS mode) or null value (ANSI mode)	SUBSTRN	returns a missing or null value with a length of zero and writes an error to the log that the third argument is invalid
the value of the *length-expression* is a missing (SAS mode) or null value (ANSI mode)	SUBSTR	returns substring from *position-expression* to the end of the *expression* and writes a warning to the log that the third argument is invalid

Examples

Example 1: Manipulating Strings with the SUBSTRN Function

The following program shows how to manipulate strings with the SUBSTRN function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(6) string result;
   dcl double position length;
   retain string 'abcd';
   drop string;
   method run();
      do position=-1 to 6;
         do length=max(-1,-position) to 7-position;
             result=substrn(string, position, length);
             output;
         end;
      end;
   end;
enddata;
run;
quit;

proc print data=test;
```

```
run;
```

Output 7.33 *Partial Output from the SUBSTRN Function*

Obs	result	position	length
1		-1	1
2		-1	2
3	a	-1	3
4	ab	-1	4
5	abc	-1	5
6	abcd	-1	6
7	abcd	-1	7
8	abcd	-1	8
9		0	0
10		0	1
11	a	0	2
12	ab	0	3
13	abc	0	4
14	abcd	0	5
15	abcd	0	6
16	abcd	0	7
17		1	-1
18		1	0
19	a	1	1
20			2

Example 2: Comparison between the SUBSTR and SUBSTRN Functions

The following program compares the results of using the SUBSTR function and the SUBSTRN function when the first argument is numeric.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char substr_result substrn_result;
   method run();
      substr_result='*' || substr('   1234.5678',2,6) || '*';
      put substr_result=;
```

```
      substrn_result='*' || substrn('1234.5678',2,6) || '*';
      put substrn_result=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
substr_result=*  1234*
substrn_result=*234.56*
```

Example 3: Using SUBSTRN with a VARCHAR Argument

The following program uses the SUBSTRN function in a string with a VARCHAR data type.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
    dcl varchar(100000) inarg inarg2 inarg3;
    dcl double l;
    method init();
       inarg = 'x';
       inarg2 = repeat(inarg,30000-1)||'abc';
       l=length(inarg2);
       inarg3 = substrn(inarg2,29998,5);
       put l= inarg3=;
       inarg2 = repeat(inarg,90000-1)||'abc';
       l=length(inarg2);
       inarg3 = substrn(inarg2,89998,5);
       put l= inarg3= ' (should be xxxab)';
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
l=30003 inarg3=xxxab
l=90003 inarg3=xxxab  (should be xxxab)
```

See Also

Functions:

- “SUBSTR (left of =) Function” on page 1182
- “SUBSTR (right of =) Function” on page 1186

SUM Function

Returns the sum of the non-null or nonmissing arguments.

Category:	Descriptive Statistics
Returned data type:	BIGINT, DECIMAL, DOUBLE
Note:	Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

SUM(*expression-1*, *expression-2* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement	At least two arguments are required.
Data type	BIGINT, DECIMAL, DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

Null and missing values are ignored and not included in the computation. If all of the arguments have missing values, the result is a missing value. If all the arguments have a null value, the result is a null value.

If any argument to this function is non-numeric, the argument is converted to DOUBLE. If any argument is DOUBLE or REAL, all arguments are converted to DOUBLE (if not so already) and the result is DOUBLE. Otherwise, if any argument is DECIMAL, all arguments are converted to DECIMAL (if not so already) and the result is DECIMAL. Otherwise, all arguments are converted to a BIGINT and the result is BIGINT.

Example

The following program illustrates the SUM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double u v w x y z;
   dcl double val1 val2 val3 val4;
   method run();
      val1=4;
      val2=3;
      val3=9;
      val4=8;
      u=sum(4,3,9,8);
      v=sum(val1, val2, val3, val4);
      w=sum(val1, val2, val3, val4, .);
      x=sum(of val1-val2, of val3-val4);
      y=sum(of val1-val2);
      z=sum(of val:);
      put u= v= w= x= y= z=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
u=24 v=24 w=24 x=24 y=7 z=24
```

SUMABS Function

Returns the sum of the absolute values of the nonmissing arguments.

Category: Descriptive Statistics

Returned data type: DOUBLE

Note: Beginning in 2025.12 for this function, if any argument is DOUBLE, all arguments are converted to DOUBLE and the result is DOUBLE. If BIGINTPROCESSING=YES is set in the PROC DS2 statement and any argument is BIGINT, all arguments are converted to BIGINT and the result is BIGINT.

Syntax

SUMABS(*value-1*[, ...*value-n*])

Required Argument

value
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

Details

If all arguments have null or missing values, then the result is a null or missing value. Otherwise, the result is the sum of the absolute values of the nonmissing values.

Examples

Example 1: Calculating the Sum of Absolute Values

The following program returns the sum of the absolute values of the nonmissing arguments.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double x;
   method run();
      x=sumabs(1,.,-2,0,3,.q,-4);
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
x=10
```

Example 2: Calculating the Sum of Absolute Values When You Use a Variable List

The following program uses a variable list and returns the sum of the absolute value of the nonmissing arguments.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
```

```
      dcl double x1 x2 x3 x4 x5 x;
      method run();
         x1 = 1;
         x2 = 3;
         x3 = 4;
         x4 = 3;
         x5 = 1;
         x = sumabs(x1, x2, x3, x4, x5);
      put x=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following results to the log:

```
x=12
```

SYSGET Function

Returns the value of the specified operating-environment variable .

Category: Special

Restriction: This function is supported in CAS only for users with administrative-level capabilities.

Syntax

SYSGET('*environment-variable*')

Required Argument

environment-variable
is a character constant, variable, or expression with a value that is the name of an environment variable under Linux..

Requirement This argument must be enclosed in single quotation marks.

Details

General Information

The SYSGET function returns the value of an environment variable as a character string. For example, this statement returns the value of the HOME environment variable under Linux:

```
here=sysget('HOME');
```

If the SYSGET function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 200.

If the value of the operating-environment variable is truncated or the variable is not defined in the operating environment, SYSGET displays a warning message in the SAS log.

Note: The case of the value that you supply in the *environment-variable* argument must agree with the case of the variable that is stored in the Linux operating environment.

TAN Function

Returns the tangent.

Category: Trigonometric

Returned data type: DOUBLE

Syntax

TAN(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value in radians.

Restriction *expression* cannot be an odd multiple of π /2

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the TAN function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
```

```
      dcl double x1 x2 x3;
      method run();
         x1=tan(0.5);
         x2=tan(0);
         x3=tan(3.14159/3);
         put x1= x2= x3=;
      end;
   enddata;
   run;
   quit;
```

SAS writes the following output to the log:

```
x1=0.54630248984379 x2=0 x3=1.73204726945457
```

See Also

Functions:

- "TANH Function" on page 1199

TANH Function

Returns the hyperbolic tangent.

Category:	Hyperbolic
Returned data type:	DOUBLE

Syntax

TANH(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Restriction	*expression* cannot be an odd multiple of π/2
Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The TANH function returns the hyperbolic tangent of the argument, which is given by the following equation.

$$\frac{e^{argument} - e^{-argument}}{e^{argument} + e^{-argument}}$$

Example

The following program illustrates the TANH function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl double a b c;
   method run();
      a=tanh(0);
      b=tanh(0.5);
      c=tanh(-0.5);
      put 'a= ' a;
      put 'b= ' b;
      put 'c= ' c;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=  0
b=  0.46211715726
c=  -0.46211715726
```

See Also

Functions:

- “TAN Function” on page 1198

TIME Function

Returns the current time of day as a numeric SAS time value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

TIME( )

Details

The TIME function does not take any arguments. It produces the current time in the form of a SAS time value.

Example

The following programs illustrate the TIME function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double current;
   method run();
      current=time();
      put current=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
current=40486.0569992065
```

```
proc ds2;
data test(overwrite=yes);
   dcl double current;
   method run();
      current=time();
      put current=time.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
current=11:14:46
```

See Also

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Functions:

- "DATE Function" on page 500
- "DATETIME Function" on page 504

TIMEPART Function

Extracts a time value from a SAS datetime value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

TIMEPART(*datetime*)

Required Argument

datetime
specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the TIMEPART function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double dttm tm;
   dcl char(10) x;
   method run();
      dttm=datetime();
      put dttm;
```

```
        x=put(timepart(dttm), time.);
        put x;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1866291827.48899
14:23:47
```

See Also

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Functions:

- "DATEPART Function" on page 503

TIMEVALUE Function

Returns the equivalent of a reference amount at a base date by using variable interest rates.

Category: Financial

Returned data type: DOUBLE

Syntax

TIMEVALUE(*base-date*, *reference-date*, *reference-amount*, *compounding-interval*, *date-1*, *rate-1*[, ...*date-n*, *rate-n*])

Required Arguments

base-date
specifies the time value of the *reference-amount* at the *base-date*.

Requirement *Base-date* is a SAS date.

Data type DOUBLE

reference-date
specifies the date of *reference-amount*.

Requirement *Reference-date* is a SAS date.

Data type DOUBLE

reference-amount
specifies the amount at the *reference-date*.

Data type DOUBLE

compounding-interval
specifies the compounding interval.

Requirement *Compounding-interval* is a SAS interval.

Data type CHAR

date
specifies the time at which *rate* takes effect. Each date is paired with a rate.

Requirement *Date* is a SAS date.

Data type DOUBLE

rate
specifies the interest rate as numeric percentage that starts on *date*. Each rate is paired with a date.

Data type DOUBLE

Details

The following details apply to the TIMEVALUE function:

- The values for rates must be between –99 and 120.
- The list of date-rate pairs does not need to be sorted by date.
- When multiple rate changes occur on a single date, the TIMEVALUE function applies only the final rate that is listed for that date.
- Simple interest is applied for partial periods.
- There must be a valid date-rate pair whose date is at or prior to both the *reference-date* and the *base-date*.

Example

- You can express the accumulated value of an investment of $1,000 at a nominal interest rate of 10% compounded monthly for one year as the following:

  Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data _null_;
   dcl double bd rd d amount_base1;
   method run();
      bd= to_double(date'2001-01-01');
      rd= to_double(date'2000-01-01');
      d= to_double(date'2000-01-01');
      amount_base1 = timevalue(bd, rd, 1000, 'month', d, 10);
      put amount_base1;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1104.71306744129
```

- If the interest rate jumps to 20% halfway through the year, the resulting calculation would be as follows:

```
proc ds2;
data _null_;
   dcl double bd rd d1 d2 amount_bases;
   method run();
      bd= to_double(date'2001-01-01');
      rd= to_double(date'2000-01-01');
      d1= to_double(date'2000-01-01');
      d2= to_double(date'2000-07-01');
      amount_base2 = timevalue(bd, rd, 1000, 'month', d1, 10, d2, 20);
      put amount_base2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1160.63657783831
```

- The date-rate pairs do not need to be sorted by date. This flexibility allows amount_base2 and amount_base3 to assume the same value:

```
proc ds2;
data _null_;
   dcl double bd rd d1 d2 amount_base3;
   method run();
      bd= to_double(date'2001-01-01');
      rd= to_double(date'2000-01-01');
      d1= to_double(date'2000-07-01');
      d2= to_double(date'2000-01-01');
      amount_base3 = timevalue(bd, rd, 1000, 'month', d1, 20, d2, 10);
      put amount_base3;
end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1160.63657783831
```

TINV Function

Returns a quantile from the *t* distribution.

Category: Quantile

Returned data type: DOUBLE

Syntax

TINV(*p*, *df*[, *nc*])

Required Arguments

p

specifies any valid expression that evaluates to a numeric probability.

Range $0 < p < 1$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

df

specifies any valid expression that evaluates to a numeric degrees of freedom parameter.

Range $df > 0$

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Optional Argument

nc

specifies any valid expression that evaluates to a numeric noncentrality parameter.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The TINV function returns the p^{th} quantile from the Student's *t* distribution with degrees of freedom *df* and a noncentrality parameter *nc*. The probability that an observation from a *t* distribution is less than or equal to the returned quantile is *p*.

TINV accepts a noninteger degree of freedom parameter *df*. If the optional parameter *nc* is not specified or is 0, the quantile from the central *t* distribution is returned.

CAUTION
For large values of nc, the algorithm can fail. In that case, a missing value is returned.

Comparisons

TINV is the inverse of the PROBT function.

Example

The following program illustrates the TINV function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
 proc ds2;
data _null_;
   dcl double x y;
   method run();
      x=tinv(.95, 2);
      y=tinv(.95, 2.5, 3);
      put x y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=2.91998558035372
y=11.0338336251942
```

See Also

Functions:

■ "PROBT Function" on page 1024

TNONCT Function

Returns the value of the noncentrality parameter from the Student's *t* distribution.

Category: Mathematical

Returned data type: DOUBLE

Syntax

TNONCT(*x*, *df*, *prob*)

Required Arguments

x
is a numeric random variable.

Data type DOUBLE

df
is a numeric degrees of freedom parameter.

Range *df* > 0

Data type DOUBLE

prob
is a probability.

Range 0 < *prob* < 1

Data type DOUBLE

Details

The TNONCT function returns the nonnegative noncentrality parameter from a noncentral *t* distribution whose parameters are *x*, *df*, and *nc*. A Newton-type algorithm is used to find a root *nc* of the equation

$$P_t(x|df, nc) - prob = 0$$

The following relationship applies to the preceding equation:

$$P_t(x|df,nc) = \frac{1}{\Gamma\left(\frac{df}{2}\right)}\int_0^{\infty} v^{\frac{df}{2}-1}\varepsilon^{-v}\int_{-\infty}^{x\sqrt{\frac{2v}{df}}}\varepsilon^{-\frac{(u-nc)^2}{2}}dudv$$

If the algorithm fails to converge to a fixed point, a missing value is returned.

Example

The following program computes the noncentrality parameter from the *t* distribution.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data work /overwrite=yes;
   dcl double x df nc prob ncc;
   method init();
      x=2;
      df=4;
      do nc=1 to 3 by .5;
         prob=probt(x, df, nc);
         ncc=tnonct(x, df, prob);
         output;
      end;
   end;
enddata;
run;
quit;

proc print data=work;
run;
```

Output 7.34 *Output from the Computations of the Noncentrality Parameter for the t Distribution*

Obs	x	df	nc	prob	ncc
1	2	4	1.0	0.76457	1.00000
2	2	4	1.5	0.61893	1.50000
3	2	4	2.0	0.45567	2.00000
4	2	4	2.5	0.30115	2.50000
5	2	4	3.0	0.17702	3.00000

TO_DATE Function

Returns a DATE value from a DOUBLE value that specifies a SAS date value.

Category: Date and Time

Returned data type: DATE

Syntax

TO_DATE(*date*)

Required Argument

date
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

A DOUBLE value that specifies a SAS date value represents the number of days between January 1, 1960, and a specified date. SAS can perform calculations on dates ranging from A.D. 1582 to A.D. 19,900. Dates before January 1, 1960, are negative numbers; dates after January 1, 1960, are positive numbers.

- SAS date values account for all leap year days, including the leap year day in the year 2000.
- SAS date values can reliably tell you what day of the week a particular day fell on as far back as September 1752, when the calendar was adjusted by dropping several days. SAS day-of-the-week and length-of-time calculations are accurate in the future to A.D. 19,900.

Example

The following program converts a DOUBLE value that specifies a SAS date value, to a DATE value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* SAS date to date */
proc ds2;
data _null_;
   dcl date da;
   dcl double d;
   method init();
      d = 22096;
      da = to_date(d);
      put d=YYMMDD10. da=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
d=2020-06-30 da=2020-06-30
```

See Also

Functions:

- “TO_DOUBLE Function” on page 1211
- “TO_TIME Function” on page 1215
- “TO_TIMESTAMP Function” on page 1216

TO_DOUBLE Function

Returns a DOUBLE value that specifies a SAS date, time, or datetime value, from a DATE, TIME, or TIMESTAMP value.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

TO_DOUBLE (*date* | *time* | *timestamp*)

Required Arguments

date
is a date constant, variable, or expression.

time
is a time constant, variable, or expression.

timestamp
is a timestamp constant, variable, or expression.

Details

The following list describes the values that can be returned by the TO_DOUBLE function:

- A SAS date value represents the number of days between January 1, 1960, and a specified date. SAS can perform calculations on dates ranging from A.D. 1582 to A.D. 19,900. Dates before January 1, 1960, are negative numbers; dates after January 1, 1960, are positive numbers.
  - SAS date values account for all leap year days, including the leap year day in the year 2000.
  - SAS date values can reliably tell you what day of the week a particular day fell on as far back as September 1752, when the calendar was adjusted by dropping several days. SAS day-of-the-week and length-of-time calculations are accurate in the future to A.D. 19,900.
- A SAS time value represents the number of seconds since midnight of the current day. SAS time values are between 0 and 86400.
- A timestamp is a record of the date and time at which a certain event occurred.
- A SAS datetime value represents the number of seconds between January 1, 1960, and an hour/minute/second within a specified date.

Examples

Example 1: Converting a TIMESTAMP Value to a DOUBLE Value

The following program converts a TIMESTAMP value to a DOUBLE value that specifies a SAS datetime value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* Timestamp to SAS datetime */
proc ds2;
data _null_;
   dcl timestamp ts;
   dcl double d_asd;
   dcl date d;
   method init();
      ts = timestamp '2019-10-19 16:51:36.0625';
      d_asd = to_double(ts);
      put ts=;
      put d_asd;
      put d_asd=DATETIME28.9;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
ts=2019-10-19 16:51:36.062500000
1887123096.0625
d_asd=19OCT2019:16:51:36.062500000
```

Example 2: Converting a Date Value to a SAS Date Value

The following program converts a DATE value to a DOUBLE value that specifies a SAS date value:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* Date to SAS date */
proc ds2;
data _null_;
   dcl date da;
   dcl double d;
   method init();
      da = date '2019-10-19';
      d = to_double(da);
      put d;
      put d=YYMMDD10.;
      put da=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
21841
d=2019-10-19
da=2019-10-19
```

Example 3: Converting a Time Value to a SAS Time Value

The following program converts a TIME value to a SAS time value:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* Time to SAS time */
proc ds2;
data _null_;
   dcl time t;
   dcl double d;
   method init();
      t = time '16:51:36.0625';
      d = to_double(t);
      put d=TIME18.9 t=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
d=16:51:36.062500000 t=16:51:36.062500000
```

Example 4: Converting a NULL Timestamp to a SAS Datetime Value

The following program converts a NULL TIMESTAMP to a SAS datetime value:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* NULL timestamp to SAS datetime */
proc ds2;
data _null_;
   dcl timestamp ts;
   dcl double d;
   method init();
      ts = null;
      d = to_double(ts);
      put d=DATETIME28.9 ts=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
d=                          . ts=
```

See Also

Functions:

- “TO_DATE Function” on page 1210

TO_TIME Function

Returns a TIME value from a DOUBLE value that specifies a SAS time value.

Category: Date and Time

Returned data type: TIME

Syntax

TO_TIME(*date*)

Required Argument

date
specifies any valid expression that represents a SAS time value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

A SAS time value represents the number of seconds since midnight of the current day. SAS time values are between 0 and 86400.

Example

The following program converts a SAS time value to a formatted time value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* SAS time to time */
proc ds2;
data _null_;
   dcl time t;
   dcl double d;
   method init();
      d = 45911.68;
```

```
        t = to_time(d);
        put d=TIME18.9 t=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
d=12:45:11.680000000 t=12:45:11.680000000
```

See Also

Functions:

- “TO_DATE Function” on page 1210
- “TO_DOUBLE Function” on page 1211
- “TO_TIMESTAMP Function” on page 1216

TO_TIMESTAMP Function

Returns a TIMESTAMP value from a DOUBLE value that specifies a SAS time value.

Category: Date and Time

Returned data type: TIMESTAMP

Syntax

TO_TIMESTAMP(*date*)

Required Argument

date
specifies any valid expression that represents a SAS datetime value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

A SAS datetime value is a DOUBLE value that represents the number of seconds between January 1, 1960, and an hour/minute/second within a specified date.

Examples

Example 1: Converting a SAS Datetime Value to a Timestamp Value

The following program converts a SAS datetime value to a timestamp value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* SAS datetime to timestamp */
proc ds2;
data _null_;
   dcl timestamp ts;
   dcl double d;
   method init();
      d = 1845773470.3;
      ts = to_timestamp(d);
      put d=DATETIME28.9 ts=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
d=28JUN2018:02:51:10.299999952 ts=2018-06-28 02:51:10.299999952
```

Example 2: Converting a SAS Datetime Value That Is Missing

The following program shows how SAS handles the conversion of a missing SAS datetime value.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
/* Missing SAS datetime to timestamp */
proc ds2;
data _null_;
   dcl timestamp ts;
   dcl double d;
   method init();
      d = .;
      ts = to_timestamp(d);
      put d=DATETIME28.9 ts=;
   end;
```

```
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
d=                          . ts=
```

See Also

Functions:

- “TO_DOUBLE Function” on page 1211
- “TO_TIME Function” on page 1215

TODAY Function

Returns the current date as a numeric SAS date value.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

TODAY( )

Details

The TODAY function does not take any arguments. It produces the current date in the form of a SAS date value, which is the number of days since January 1, 1960.

For more information about how DS2 handles dates, see “DS2 Expressions” in *SAS DS2 Programmer’s Guide*.

Example

The following program illustrates the TODAY function:

```
proc ds2;
```

```
data test(overwrite=yes);
   dcl double td;
   dcl char(10) tday;
   method run();
      td=today();
      tday=put(td, date.);
      put td;
      put tday;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
21600
20FEB19
```

TRANSLATE Function

Replaces specific characters in a character expression.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

TRANSLATE(*expression*, *to-characters*, *from-characters*)

Required Arguments

expression
specifies any valid expression that evaluates or can be coerced to a character string. *expression* contains the original character value.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

to-characters
specifies the characters that you want TRANSLATE to use as substitutes.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

from-characters
specifies the characters that you want TRANSLATE to replace.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Values of *to-characters* and *from-characters* correspond on a character-by-character basis; TRANSLATE changes the first character in *from-characters* to the first character in *to-characters*, and so on. If *to-characters* has fewer characters than *from-characters*, TRANSLATE changes the extra *from-characters* characters to blanks. If *to-characters* has more characters than *from-characters*, TRANSLATE ignores the extra *to-characters*.

Comparisons

The TRANWRD function differs from the TRANSTRN function because TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.

The TRANSLATE function converts every occurrence of a user-supplied character to another character. TRANSLATE can scan for more than one character in a single call. In doing this scan, however, TRANSLATE searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The TRANWRD function differs from TRANSLATE in that it scans for words (or patterns of characters) and replaces those words with a second word (or pattern of characters).

Example

The following program illustrates the TRANSLATE function.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(10) x y;
   method run();
      x=translate('XYZW', 'AB', 'VW');
      y='AABBAABABB';
      y=translate(y, '12', 'AB');
      put x;
      put y;
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following output to the log:

```
XYZB
1122112122
```

Functions:

- “TRANSTRN Function” on page 1221
- “TRANWRD Function” on page 1224

TRANSTRN Function

Replaces or removes all occurrences of a substring in a character string.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

TRANSTRN(*source-expression*, *target-expression*, *replacement-expression*)

Required Arguments

source-expression
specifies any valid expression that evaluates or can be coerced to a character string and whose characters you want to translate.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

target-expression
specifies any valid expression that evaluates or can be coerced to a character string and whose characters are searched for in *source-expression*.

Requirement: The length for *target-expression* must be greater than zero.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

replacement-expression
specifies any valid expression that evaluates or can be coerced to a character string and that replaces *target-expression*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The TRANSTRN function replaces or removes all occurrences of a given substring within a character string. The TRANSTRN function does not remove trailing blanks in the *target-expression* string and the *replacement-expression* string. To remove all occurrences of *target*, specify *replacement-expression* as TRIMN(' ').

Comparisons

The TRANWRD function differs from the TRANSTRN function because TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.

The TRANSLATE function converts every occurrence of a user-supplied character to another character. TRANSLATE can scan for more than one character in a single call. In doing this scan, however, TRANSLATE searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The TRANSTRN function differs from TRANSLATE in that TRANSTRN scans for substrings and replaces those substrings with a second substring.

Examples

Example 1: Replacing All Occurrences of a Word

In this program, the TRANSTRN function is used to replace **`Mrs.`** and **`Miss`** with **`Ms.`**

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(20) name;
   method run();
      name='Mrs.  Joan Smith';
      name=transtrn(name, 'Mrs.', 'Ms.');
      put name;
```

```
      name='Miss Alice Cooper';
      name=transtrn(name, 'Miss', 'Ms.');
      put name;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Ms.  Joan Smith
Ms. Alice Cooper
```

Example 2: Removing Blanks from the Search String

In this program, the TRIM function is used with *target* to exclude blanks. If you did not include the TRIM function, the TRANSTRN function would not replace the source string because the target string contains blanks.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test (overwrite=yes);
   dcl char(10) target;
   dcl char(3) replacement;
   dcl char(8) salelist salelist2;
   method run();
      salelist='CATFISH';
      target='FISH';
      replacement='NIP';
      salelist2=transtrn(salelist, trim(target), replacement);
      put salelist2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
CATNIP
```

Example 3: Zero Length in the Third Argument of the TRANSTRN Function

The following program illustrates the results of the TRANSTRN function when the third argument, *replacement*, has a length of zero. In DS2, a character constant that consists of two quotation marks with a blank in between them represents a single blank, and not a zero-length string. In the following program, the results for *string1* are different from the results for *string2*.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
```

```
data _null_;
   dcl char string1 string2;
   method run();
      string1='*' || transtrn('abcxabc', 'abc', trimn(' ')) || '*';
      put string1=;
      string2='*' || transtrn('abcxabc', 'abc', ' ') || '*';
      put string2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
string1=*x*
string2=* x *
```

See Also

Functions:

- "TRANSLATE Function" in *SAS Functions and CALL Routines: Reference*
- "TRANWRD Function" on page 1224

TRANWRD Function

Replaces all occurrences of a substring in a character string.

Category: Character

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

TRANWRD(*source-expression*, *target-expression*, *replacement-expression*)

Required Arguments

source-expression
specifies any valid expression that evaluates or can be coerced to a character string whose characters you want to replace.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

target-expression
specifies any valid expression that evaluates or can be coerced to a character string and that is searched for in *source-expression*.

Requirement The length of the *target-expression* must be greater than zero.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

replacement-expression
specifies any valid expression that evaluates or can be coerced to a character string and that replaces *target-expression*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The TRANWRD function replaces all occurrences of a given substring (or a pattern of characters) within a character string. The TRANWRD function does not remove trailing blanks in the *target-expression* string and the *replacement-expression* string.

Comparisons

The TRANWRD function differs from the TRANSTRN function because TRANSTRN allows the replacement string to have a length of zero. TRANWRD uses a single blank instead when the replacement string has a length of zero.

The TRANSLATE function converts every occurrence of a user-supplied character to another character. TRANSLATE can scan for more than one character in a single call. In doing this, however, TRANSLATE searches for every occurrence of any of the individual characters within a string. That is, if any letter (or character) in the target string is found in the source string, it is replaced with the corresponding letter (or character) in the replacement string.

The TRANWRD function differs from TRANSLATE in that it scans for substrings (or patterns of characters) and replaces those substrings with a second substring (or pattern of characters).

Examples

Example 1: Replacing All Occurrences of a Word

The following program illustrates replacing all occurrences of a substring using the TRANWRD function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(16) text1 text2 nametrn1 nametrn2;
   method run();
      text1='Mrs. Jane Doe';
      text2='Miss Joan Smith';
      nametrn1=tranwrd(text1, 'Mrs.', 'Ms.');
      nametrn2=tranwrd(text2, 'Miss', 'Ms.');
      put nametrn1;
      put nametrn2;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
Ms. Jane Doe
Ms. Joan Smith
```

Example 2: Removing Blanks from the Search String by Changing the Data Type

This program illustrates incorrect data type declarations. The TRANWRD function does not replace the source string because TARGET is declared as `char(10)` and the TRANWRD function searches for the character string `'pail '` and not `''pail'`.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(100) text finaltext;
   dcl char(10) target;
   dcl varchar(10) rplc;
   method run();
      text='Believe and act as if it were impossible to pail.
          -Charles F. Kettering';
      target='pail';
      rplc='fail';
      finaltext=tranwrd(text, target, rplc);
      put finaltext=;
   end;
enddata;
run;
quit;
```

This line is written to the SAS log.

```
finaltext=Believe and act as if it were impossible to pail. -Charles F. Kettering
```

By changing the data type declaration to `VARCHAR(10)`, trailing blanks are excluded from the search:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(100) text finaltext;
   dcl varchar(10) target;
   dcl varchar(10) rplc;
   method run();
      text='Believe and act as if it were impossible to pail.
         -Charles F. Kettering';
      target='pail';
      rplc='fail';
      finaltext=tranwrd(text, target, rplc);
      put finaltext=;
   end;
enddata;
run;
quit;
```

This line is written to the SAS log.

```
finaltext=Believe and act as if it were impossible to fail. -Charles F. Kettering
```

Example 3: Using TRIM to Remove Blanks from the Search String

In this program, the TRANWRD function does not replace the source string because the target string contains blanks.

Note: In this example, code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char prod target replacement salelist;
   method run();
      prod='CATFISH';
      target='FISH';
      replacement='NIP';
      prod=tranwrd(prod, target, replacement);
      put prod;
   end;
enddata;
run;
quit;
```

The DECLARE statement pads target with blanks to the length of 8, which causes the TRANWRD function to search for the character string 'FISH ' in PROD. Because the search fails, this line is written to the SAS log: CATFISH

You can use the TRIM function to exclude trailing blanks from a target or replacement variable. Use the TRIM function with target:

```
prod=tranwrd(prod, trim(target), replacement;
put prod;
```

SAS writes the following output to the log:

```
CATNIP
```

Example 4: Removing Repeated Commas

You can use the TRANWRD function to remove repeated commas in text and replace the repeated commas with a single comma. In this program, the TRANWRD function is used twice: to replace three commas with one comma and to replace the ending two commas with a period:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(70) mytxt newtext newtext2;
   method run();
      mytxt='If you exercise your power to vote,,,then your opinion
          will be heard,,';
      newtext=tranwrd(mytxt, ',,,', ',');
      newtext2=tranwrd(newtext, ',,' , '.');
      put mytxt=;
      put newtext=;
      put newtext2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
mytxt=If you exercise your power to vote,,,then your opinion will be heard,,
newtext=If you exercise your power to vote,then your opinion will be heard,,
newtext2=If you exercise your power to vote,then your opinion will be heard.
```

TRIGAMMA Function

Returns the value of the trigamma function.

Category: Mathematical

Returned data type: DOUBLE

Syntax

TRIGAMMA(*expression*)

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Restriction: Nonpositive integers are invalid.

Data type: DOUBLE

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The TRIGAMMA function returns the derivative of the digamma function. For *expression* > 0, the TRIGAMMA function is the second derivative of the lgamma function.

Example

The following program illustrates the TRIGAMMA function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x;
   method run();
      x=trigamma(3);
      put x=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x=0.39493406684822
```

See Also

Functions:

- “DIGAMMA Function” on page 522
- “LGAMMA Function” on page 826

TRIM Function

Removes trailing blanks from a character expression, and returns a string with a length of zero if the expression is missing.

Category:	Character
Alias:	TRIMN
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

TRIM('*expression*')

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type	CHAR, NCHAR, NVARCHAR, VARCHAR
See	“DS2 Expressions” in *SAS DS2 Programmer's Guide*

Details

The TRIM function copies a character argument, removes trailing blanks, and returns the trimmed argument as a result. If the argument is blank, TRIM returns a string with a length of zero. TRIM is useful after concatenating because concatenation does not remove trailing blanks.

Note: The TRIM function removes both blanks and whitespace characters as defined by the Unicode standard. Consequently, the TRIM function also handles DBCS blanks and shift out/shift in (SO/SI) escape codes. For more information

about the Unicode whitespace character standard, see Wikipedia: Unicode character property.

Examples

Example 1: Removing Trailing Blanks

The following program illustrates the TRIM function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl char(17) string result;
   method run();
      string='Testscore   ';
      result=trim(string)||'File.xls';
      put result;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
TestscoreFile.xls
```

Example 2: Concatenating a Blank Character Expression

The following program illustrates how to use the TRIM function to concatenate a blank character.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data new(overwrite=yes);
   dcl char x z y;
   method run();
      x='A'||trim(' ')||'B';
      z=' ';
      y='>'||trim(z)||'<';
      put x;
      put y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
AB
><
```

See Also

Functions:

- “COMPRESS Function” on page 456
- “LEFT Function” on page 816
- “STRIP Function” on page 1179

TRUNC Function

Truncates a numeric value to a specified length.

Category: Truncation

Returned data type: DOUBLE

Syntax

TRUNC(*expression*, *length-expression*)

Required Arguments

expression
specifies any valid expression that evaluates to a numeric value.

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

length-expression
specifies any valid expression that evaluates to a numeric value.

Range 3–8

Data type DOUBLE

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The TRUNC function truncates a full-length numeric expression (stored as a DOUBLE) to a smaller number of bytes, as specified in *length-expression* and pads the truncated bytes with 0s. The truncation and subsequent expansion duplicate the effect of storing numbers in less than full length and then reading them.

Example

The following program illustrates the TRUNC function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double i x;
   method run();
      do i=3 to 8;
         x=trunc(3.1,i);
         put x;
      end;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
3.099609375
3.09999847412109
3.09999999403953
3.09999999997671
3.0999999999999
3.1
```

TSLVL Function

Provides information about the SAS installation image, including the release number, hot fixes, and maintenance images.

Category:	Installation Information
Returned data type:	VARCHAR(n)

Syntax

TSLVL(*binary-file*[,*option*[*option-n*]])

Required Argument

binary-file
specifies the name of a SAS binary file from the SAS installation image, minus the file extension. Valid file names for DS2 include tkeds, tkmk, tkedsq, tkeds2, and tkedspem. tkeds is the name of the binary file for the DS2 compiler. When you specify a binary file name without options, SAS returns high-level information about the SAS installation image, such as the product name, the Technical Support level, and Maintenance level. The information is not specific to the binary file.

Data type CHAR(n)

Optional Arguments

The options are not case sensitive.

A
returns additional track information.

Data type CHAR(n)

B
writes script information in this format:`<Script DVD>/script/<Script Name>.bld`

Data type CHAR(n)

```
proc ds2;
data _null_;
  method init();
    dcl varchar(30) x;
    x = tslvl('tkeds', 'b');
    put x=;
   end;
enddata;
run;
quit;
```

```
x=tkeds/script/tkeds.bld
```

C
changes the output separator from a comma to a colon. Also decodes the image description if the I option is specified.

Requirement The C option must be specified with at least one of the D, P, T, or I options.

Data type CHAR(n)

```
proc ds2;
```

```
data _null_;
  method init();
   dcl varchar(128) x;
   x = tslvl('tkeds', 'cdpti');
   put x=;
  end;
enddata;
run;
quit;
```

```
x=:V.04.00M0P11012022:tktslang:day/mva-vbviya:DS2 extension
```

D

returns the port date (for example, V.04.00M0P10302022).

Data type CHAR(n)

E

returns the date as a UNIX date, which is the number of seconds since January 1, 1970. SAS dates are based on the number of seconds since January 1, 1960.

Data type CHAR(n)

H

includes hot fix information.

Data type CHAR(n)

I

includes a file description. Use with the Z option to decode the field.

Data type CHAR(n)

M

returns maintenance release information.

Data type CHAR(n)

N

suppresses some error messages if the module is not found.

Data type CHAR(n)

P

returns the product number.

Data type CHAR(n)

S

returns a colon-separated list that comprises the Script DVD, Script Name, and Script Location in that order.

Data type CHAR(n)

Note: Use the Z option to decode the fields.

```
<Script DVD>:<Script Name>:<Script Location>
```

```
proc ds2;
data _null_;
  method init();
    dcl varchar(35) x;
    x = tslvl('sasxkern', 'sz');
    put x=;
  end;
enddata;
run;
quit;
```

```
x=sup:sasxkern:/sas/day/mva-vbviya,
```

T

returns SAS track information.

Data type CHAR(n)

Z

decodes any fields that are encoded.

Data type CHAR(n)

Details

When specifying the TSLVL function, separate the name of the binary file from the options with a comma. Specify all desired options in a single string.

The output for the TSLVL function returns one character string for each requested information item, separated by commas to facilitate parsing the results. Specify the C option to use colons instead.

If any information for an image is not available, you might receive the following errors:

- ImageNotLoaded indicates that the requested image is not loaded.
- VersionNotFound indicates that version information could not be found.
- NotAvailable indicates other problems in obtaining version information.

Example

The following example calls the TSLVL function twice. The first instance returns the SAS Viya track, Version number (.04), Technical Support level (0), and Maintenance level (0). This was the fourth version of the SAS Viya platform. The second instance requests the track, the port date, and the UNIX time at which the image was built. This image was built in the main development track for the SAS Viya platform on October 30, 2022.

```
proc ds2;
```

```
 data _null_;
 method init();
   dcl varchar(15) y;
   dcl varchar(50) a;
   y=tslvl('sasxkern');
   put y=;
   a=tslvl('sasxkern','tde');
   put a=;
  end;
enddata;
run;
quit;
```

```
y=V.04 TS0M0
a=day/mva-vbviya,V.04.00M0P10302022,1667167175
```

UNIFORM Function

Returns a random variate from a uniform distribution.

Note: This function is no longer supported. Use the RAND('UNIFORM') function on page 1071 instead.

UPCASE Function

Converts all letters in an argument to uppercase.

Category: Character

Alias: UPPER

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

UPCASE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The UPCASE function copies a character expression, converts all lowercase letters to uppercase letters, and returns the altered value as a result.

Comparisons

The LOWCASE function converts all letters in an argument to lowercase letters. The UPCASE function converts all letters in an argument to uppercase letters.

Example

The following program illustrates the UPCASE function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data names(overwrite=yes);
   dcl char(13) name;
   method run();
      name='SaraH'; output;
      name='Mylinda'; output;
      name='Ryan'; output;
      name='MaRk T. Smith'; output;
   end;
enddata;
run;
quit;

proc ds2;
data test(overwrite=yes);
   dcl char(13) ucname;
   method run();
      set names;
      ucname=upcase(name);
      put ucname;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
SARAH
MYLINDA
RYAN
MARK T. SMITH
```

See Also

Functions:

- "LOWCASE Function" on page 843

URLDECODE Function

Returns a string that was decoded using the URL escape syntax.

Category: Web Tools

Syntax

URLDECODE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

The Basics

The URL escape syntax is used to hide characters that might otherwise be significant when used in a URL.

A URL escape sequence can be one of the following:

- a plus sign, which is replaced by a blank.
- a sequence of three characters beginning with a percent sign and followed by two hexadecimal characters. This pattern is replaced by a single character that has the specified hexadecimal value.

expression can be decoded using either SAS session encoding or UTF-8 encoding.

Character Verification

The URLDECODE and URLENCODE functions do not verify that the bytes that are produced by the escape sequences are valid characters based on the encoding.

Length of Returned Variable

If the URLDECODE function returns a value to a variable that has not previously been assigned a length, then that variable is given the length of the argument.

Example

The following program decodes three URL strings.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(15) x1 x2 x3;
   method run();
      x1=urldecode('abc+def');
      x2=urldecode('why%3F');
      x3=urldecode('%41%42%43%23%31');
      put x1= x2= x3=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=abc def x2=why? x3=ABC#1
```

See Also

Functions:

- “URLENCODE Function” on page 1240

URLENCODE Function

Returns a string that was encoded using the URL escape syntax.

Category: Web Tools

Syntax

URLENCODE(*expression*)

Required Argument

expression
specifies any valid expression that evaluates or can be coerced to a character string.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

The Basics

expression can be encoded using either SAS session encoding or UTF-8 encoding.

The URLENCODE function encodes characters that might otherwise be significant when used in a URL. This function encodes all characters except for the following:

- all alphanumeric characters
- dollar sign ($)
- hyphen (-)
- underscore (_)
- at sign (@)
- period (.)
- exclamation point (!)
- asterisk (*)
- open parenthesis (( ) and close parenthesis ( ))
- comma (,)

Note: The encoded string might be longer than the original string. Ensure that you consider the additional length when you use this function.

Character Verification

The URLDECODE and URLENCODE functions do not verify that the bytes that are produced by the escape sequences are valid characters based on the encoding.

Example

The following program encodes a URL string.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(7) x1;
   dcl varchar(9) x2;
   method run();
      x1=urlencode('abc def');
      put x1=;
      x2=urlencode('abc def');
      put x2=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x1=abc%20d
x2=abc%20def
```

See Also

Functions:

- "URLDECODE Function" on page 1239

USS Function

Returns the uncorrected sum of squares.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

USS(*expression* [, ...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value.

Requirement	At least one non-null or nonmissing argument is required. Otherwise, the function returns a null or missing value.
Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the USS function:

```
proc ds2;
data values(overwrite=yes);
   dcl double x1 x2 x3 x4;
   method run();
      x1=4;
      x2=2;
      x3=3.5;
      x4=6;
      output;
   end;
enddata;
run;
quit;

proc ds2;
data new (overwrite=yes);
   dcl double val1 val2 val3;
   method run();
      set values;
      val1=uss(of x1-x4);
      put val1;
      val2=uss(of x1-x4, .);
      put val2;
      val3=uss(of val1-val2);
      put val3;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
68.25
68.25
9316.125
```

UUIDGEN Function

Returns the short form of a Universally Unique Identifier (UUID).

Category:	Special
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR

Syntax

UUIDGEN( )

Without Arguments

The UUIDGEN function has no arguments.

Details

The UUIDGEN function returns a UUID (a unique value) for each call. The default result is 36 characters long and it looks like this:

```
5ab6fa40-426b-4375-bb22-2d0291f43319
```

Example

The following program returns a UUID. Note that a variable declaration of 36 characters is required.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl char(36) x;
   method run();
      x=uuidgen();
      put x;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log. Each UUID is unique.

```
25C752D5-AFA1-4932-BEE6-39E4006C2AAB
```

VAR Function

Returns the variance.

Category:	Descriptive Statistics
Returned data type:	DOUBLE

Syntax

VAR(*expression-1*, *expression-2* [,...*expression-n*])

Required Argument

expression
specifies any valid expression that evaluates to a numeric value. The argument list can consist of a variable list.

Requirement	At least two non-null or nonmissing arguments are required. Otherwise, the function returns a null or missing value.
Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Example

The following program illustrates the VAR function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data new (overwrite=yes);
   vararray double a[4];
   dcl double x1 x2 x3;

   method init();
      a:=(4, 2, 3.5, 6);
   end;

   method run();
      x1=var(of a1-a4);
      put x1;
      x2=var(of a1, a4, .);
      put x2;
      x3=var(of x1-x2);
      put x3;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
2.72916666666666
2
0.26584201388888
```

VERIFY Function

Returns the position of the first character that is unique to an expression.

Category:	Character
Returned data type:	DOUBLE

Syntax

VERIFY(*target-expression*, *search–expression*)

Required Arguments

target-expression
specifies any valid expression that evaluates or can be coerced to a character string that is to be searched.

Requirement Literal character strings must be enclosed in single quotation marks.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

search-expression
specifies any valid expression that evaluates or can be coerced to a character string.

Requirement Literal character strings must be enclosed in single quotation marks.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The VERIFY function returns the position of the first character in *target-expression* that is not present in *search-expression*. If there are no characters in *target-expression* that are unique from those in *search-expression*, VERIFY returns a 0.

Comparisons

The INDEX function returns the position of the first occurrence of *search-expression* that is present in *target-expression* where the VERIFY function returns the position of the first character in *target-expression* that does not contain *search-expression*.

Example

The following programs illustrate the VERIFY function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double z;
   dcl char x y;
   method run();
      x='abc';
      y='abcdef';
      z=verify(y,x);
      put z;
```

```
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
4
```

```
proc ds2;
data test(overwrite=yes);
   dcl double z;
   dcl char x y;
   method run();
      x='abcdef';
      y='abcdef';
      z=verify(y,x);
      put z;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0
```

VFORMAT Function

Returns the format that is associated with the specified global variable.

Category:	Variable Information
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR
Note:	Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).
See:	“Subscript Operator” on page 2169

Syntax

VFORMAT(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Restriction You cannot use an expression as an argument.

Data type All data types

variable-array
specifies the name of a variable array.

See "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i
specifies the element number of a variable in the specified varlist or variable array.

Requirement *i* must be contained in square brackets ([ ]).

Details

VFORMAT returns the complete format name, which includes the width and the period (for example, $CHAR20.).

Example

The following program returns the format of a character variable:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(7) str having format $char7.;
   dcl varchar a;
   method run();
```

```
        a = vformat(str);
        put a=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=$char7.
```

VGETVALUE Function

Gets the value of the specified variable and assigns it to another variable.

Category:	Variable Assignment
Returned data type:	INTEGER
See:	“Subscript Operator” on page 2169

Syntax

VGETVALUE (*source-variable*, *destination-variable*)

Required Arguments

source-variable
specifies the global variable from which the data value is to be retrieved. A global scalar variable, element of a variable array, or element of a varlist is a

valid argument. Variable array and varlist elements must be specified using a subscript operator.

Restriction The following are not supported as the *source-variable*: a local variable, package attribute that is accessed with the dot operator, element of a temporary array, or an expression.

Data type All data types

destination-variable
specifies the variable to which the retrieved data value is to be written. A local or global variable, an element of a temporary or variable array, or an element of a varlist is a valid argument. Array and varlist elements must be specified using a subscript operator.

Restriction You cannot use an expression as an argument.

Data type All data types

Details

The VGETVALUE function gets the value of *source- variable*, converts the value to the type of the *destination-variable*, and assigns the converted value to *destination-variable*. When the *source- variable* and the *destination-variable* are the same type, no data conversion occurs.

The value obtained by VGETVALUE is of a built-in data type rather than a varlist type. For example, if the first element of a varlist is a DOUBLE variable, the following request obtains the DOUBLE data value from the first element of the varlist, converts the obtained value to the type of variable `x`, and writes the converted value to variable `x`.

```
VGETVALUE(varlist_name[1], x)
```

The VGETVALUE function returns a status indicator. A 0 (zero) is returned for successful assignment of the value from the first argument to the *destination-variable*. If there is an error, the *destination-variable* is assigned SAS missing or ANSI null and a nonzero value is returned.

For an example of using the VGETVALUE function in a DS2 program, see "Example: Getting Data Values in a Varlist" in *SAS DS2 Programmer's Guide*.

Functions:

VINARRAY Function

Returns a value that indicates whether the specified variable is a member of an array.

Category: Variable Information

Returned data type: INTEGER

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).

See: "Subscript Operator" on page 2169

Syntax

VINARRAY(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Restriction: You cannot use an expression as an argument.

Data type: All data types

variable-array
specifies the name of a variable array.

See: "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See: "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i

specifies the element number of the specified variable array or named varlist.

Note *i* must be contained in square brackets ([ ]).

Details

VINARRAY returns a value of 1 if the given variable is a member of a variable array. Otherwise, VINARRAY returns a value of 0.

Examples

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

Example 1: Variable Test

The following program returns a value (0 or 1) depending on whether the specified variable is a member of an array:

```
proc ds2;
data _null_;
   dcl  int a b c d;
   vararray int x[3] a b c;
   method init();
      dcl int c_in;
      dcl int d_in;
      c_in=vinarray(c);  /* c is in array x */
      d_in=vinarray(d);  /* d is not in an array */
      put c_in=;
      put d_in=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
c_in=1
d_in=0
```

Example 2: Varlist Test

The following program returns a value (0 or 1) depending on whether the specified variable is a member of an array:

```
proc ds2;
data _null_;
```

```
    dcl double x y;
    varlist lst [x];
    method init();
    if (VINARRAY(x)) then put 'x in array';
      else put 'x not in array';

    if (VINARRAY(y)) then put 'y in array';
      else put 'y not in array';
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
x not in array
y not in array
```

VINFORMAT Function

Returns the informat that is associated with the specified variable.

Category:	Variable Information
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR
Note:	Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).
See:	“Subscript Operator” on page 2169

Syntax

VINFORMAT(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Restriction You cannot use an expression as an argument.

Data type All data types

variable-array
specifies the name of a variable array.

See "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i
specifies the element number of a variable in the specified varlist or variable array.

Requirement *i* must be contained in square brackets ([ ]).

Details

VINFORMAT returns the complete informat name, which includes the width and the period (for example, $CHAR20.).

Example

The following program returns an informat that is associated with the specified variable:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(10) str having informat $char5.;
   method run();
```

```
        a=vinformat(str);
        put a=;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=$char5.
```

VLABEL Function

Returns the label that is associated with the specified variable.

Category:	Variable Information
Returned data type:	CHAR, NCHAR, NVARCHAR, VARCHAR
Note:	Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).
See:	“Subscript Operator” on page 2169

Syntax

VLABEL(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Data type All data types

variable-array
specifies the name of a variable array.

See "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i
specifies the element number of a variable in the specified varlist or variable array.

Requirement *i* must be contained in square brackets ([ ]).

Details

VLABEL returns the label that is associated with the specified variable. If there is no label, VLABEL returns the variable name.

Example

The following program returns a label for a specified variable:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl varchar(10) fname having label 'First Name';
   method run();
      a=vlabel(fname);
      put a=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=First Name
```

- “VTYPE Function” on page 1267

VLENGTH Function

Returns the size of the specified variable.

Category: Variable Information

Returned data type: BIGINT

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).

See: “Subscript Operator” on page 2169

Syntax

VLENGTH(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Restriction: You cannot use an expression as an argument.

Data type: All data types

variable-array
specifies the name of a variable array.

See "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i
specifies the element number of a variable in the specified varlist or variable array.

Requirement *i* must be contained in square brackets ([ ]).

Details

The length of numeric data types is defined as the maximum number of digits used by the data type of the column, or the precision of the data. For character types, this is the length in characters of the data; for binary data types, this is the length in bytes of the data. For the TIME, TIMESTAMP, and all interval data types, this is the number of characters in the character representation of this data.

Example

The following program returns the length of the specified variable:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
  dcl char(7) str;
  dcl double a;
  method run();
     str='World';
     a=vlength (str);
     put a=;
  end;
run;
quit;
```

SAS writes the following output to the log:

```
a=7
```

- “VTYPE Function” on page 1267

VNAME Function

Returns the name of the specified variable.

Category: Variable Information

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).

See: “Subscript Operator” on page 2169

Syntax

VNAME(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Restriction: You cannot use an expression as an argument.

Data type: All data types

variable-array
specifies the name of a variable array.

See "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i
specifies the element number of a variable in the specified varlist or variable array.

Requirement *i* must be contained in square brackets ([ ]).

Example

The following program returns the name of the specified variable:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   vararray int x[3] a b c;
   dcl char y;
   method run();
      y=vname(x[1]);
      put y=;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
y=a
```

VSETMISSING Function

Assigns a missing or null value to the specified variable or variables.

Category: Variable Assignment

Returned data type: INTEGER

See: "DS2 Modes for Nonexistent Data" in *SAS DS2 Programmer's Guide*

Syntax

VSETMISSING(*variable-name1*[,...*variable-nameN*])

Required Argument

variable-name(s)
specifies the name of one or more global variables in a comma-separated argument list. A global scalar variable, variable array, element of a variable array or a varlist, and an abbreviated variable list are valid arguments. You can mix arguments of different types in the argument list.

Variable arrays and abbreviated variable lists must be specified with the OF operator. For example:

```
vsetmissing(of _all_)
```

For more information, see "OF Operator" on page 2158.

Restriction: The following are not supported as arguments: local variables, package attributes that are accessed with the dot operator, and temporary arrays.

Data type: All data types

Note: Type variable lists and variable arrays that contain a type variable list specification are supported as arguments.

Details

The VSETMISSING function is similar to the DATA step MISSING call routine, except that VSETMISSING recognizes DS2 data types and supports ANSI mode in addition to SAS mode.

The VSETMISSING function assigns either a SAS missing value or ANSI null to each variable in the argument list based on the variable's data type and the DS2 mode (ANSI or SAS) in which the program is running.

- In ANSI mode, variables of all data types are assigned ANSI null.
- In SAS mode, variables of type DOUBLE or fixed-length CHARACTER are assigned SAS missing. Variables of all other data types are assigned ANSI null.

The VSETMISSING function returns a status indicator. A 0 (zero) is returned upon successful assignment of SAS missing or ANSI null to all pertinent arguments in the argument list. If there is an error, an error message is printed to the log for the argument that failed and a nonzero value is returned.

These are all valid expressions:

```
vsetmissing(b)
vsetmissing(b, c, d, e)
vsetmissing(z, of a[*], y)
vvsetmissing(y, of s:, z)
vsetmissing(of _all_)
vsetmissing(z, v[1], a[3], y)
vsetmissing(x, y, of double)
vsetmissing(OF x y z a[*])
vsetmissing(OF sum int)
```

Note: The location of the OF operator and use of commas in the argument list is flexible.

Example

Here is an example of how the VSETMISSING function can be used in a DS2 program. The example uses the VSETMISSING function with abbreviated variable lists to clear values from specified table columns and all table columns.

Note: This example is submitted to SAS using the DS2 procedure.

```
proc ds2;
package annual_record;
  dcl double sales_q1 sales_q2 sales_q3 sales_q4 having format 8.2;
  dcl double profit_q1 profit_q2 profit_q3 profit_q4 having format 8.2;

  /* Set the sales package attributes to missing. */
  method clear_sales();
    vsetmissing(of sales:);
  end;
```

```
  /* Set the profit package attributes to missing. */
  method clear_profit();
    vsetmissing(of profit:);
  end;

  /* Set all package attributes to missing. */
  method clear_all();
    vsetmissing(of _all_);
  end;

  method print_report();
    put 'QUARTER    SALES    PROFIT';
    put '   1    ' sales_q1 profit_q1;
    put '   2    ' sales_q2 profit_q2;
    put '   3    ' sales_q3 profit_q3;
    put '   4    ' sales_q4 profit_q4;
    put;
  end;
endpackage;

data _null_;
  method init();
    dcl package annual_record record();

    record.sales_q1 = 1001.50;
    record.sales_q2 = 155.25;
    record.sales_q3 = 405.00;
    record.sales_q4 = 2000.50;

    record.profit_q1 = 24.00;
    record.profit_q2 = 75.00;
    record.profit_q3 = 26.00;
    record.profit_q4 = 100.00;

    record.print_report();
    record.clear_profit();
    record.print_report();
    record.clear_all();
    record.print_report();
  end;
enddata;
run;
quit;
```

Here is the output that is written to the SAS log:

```
QUARTER    SALES    PROFIT
   1      1001.50    24.00
   2       155.25    75.00
   3       405.00    26.00
   4      2000.50   100.00

QUARTER    SALES    PROFIT
   1      1001.50       .
   2       155.25       .
   3       405.00       .
   4      2000.50       .

QUARTER    SALES    PROFIT
   1          .         .
   2          .         .
   3          .         .
   4          .         .
```

VSETVALUE Function

Sets a variable to a specified value.

Category:	Variable Assignment
Returned data type:	INTEGER
Tip:	Use the VSETMISSING function to clear variable values.
See:	"Subscript Operator" on page 2169

Syntax

VSETVALUE (*destination-variable*, *value*)

Required Arguments

destination-variable
specifies the global variable to which the data value is to be written. A global scalar variable, element of a variable array, or element of a varlist is a valid argument. Variable array and varlist elements must be specified using a subscript operator.

Restriction: The following are not supported as a *destination-variable*: a local variable, package attribute that is accessed with the dot operator, temporary array element, or an expression.

Data type: All data types

value
specifies a data value. Any expression that evaluates to a scalar value is valid.

Data type: All data types

Details

The VSETVALUE function sets a data value for the *destination-variable*. The *destination-variable* can be the name of a scalar variable, an element of a variable array, or an element of a varlist.

When the *value* is not of the same type as the *destination-variable*, the scalar value is converted to the type of the *destination-variable* before assignment to the *destination-variable*. For information about type conversions, see "DS2 Automatic Type Conversions for Expression Operands" in *SAS DS2 Programmer's Guide*. When the *value* and the *destination-variable* are of the same type, no data conversion occurs.

The VSETVALUE function returns a status indicator. A 0 (zero) is returned for successful assignment of *value* to the *destination-variable*. If there is an error, the *destination-variable* is assigned SAS missing or ANSI null and a nonzero value is returned.

Here are some examples of valid expressions:

```
vsetvalue(v[1], 42.42);
vsetvalue(v[2], y);
vsetvalue(v[3], x+y*m())
```

For an example of using the VSETVALUE function in a DS2 program, see "Example: Setting Data Values in a Varlist" in *SAS DS2 Programmer's Guide*.

VTYPE Function

Returns the full name of the data type that is associated with a variable.

Category: Variable Information

Returned data type: CHAR, NCHAR, NVARCHAR, VARCHAR

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. The index element in *variable-array* and *varlist* must be contained by square brackets ([ ]).

See: "Subscript Operator" on page 2169

Syntax

VTYPE(*variable* | *variable-array*\[*i* \] | *varlist*\[*i* \])

Required Arguments

variable
specifies the name of a global scalar variable.

Restriction: You cannot use an expression as an argument.

Data type: All data types

variable-array
specifies the name of a variable array.

See: "Variable Arrays" in *SAS DS2 Programmer's Guide*

varlist
specifies the name of a varlist.

See "DS2 Varlists" in *SAS DS2 Programmer's Guide*

Optional Argument

i

specifies the element number of a variable in the specified varlist or variable array.

Requirement *i* must be contained in square brackets ([ ]).

Details

VTYPE returns the data type name for the data type of the variable.

Example

The following program returns the name of the data type that is associated with the specified variable:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
  dcl double d;
  dcl timestamp t;
  dcl nvarchar(10) n;
  method run();
     declare char(20) a b c;
     a=vtype(d);
     put a=;
     b=vtype(t);
     put b=;
     c=vtype(n);
     put c=;
  end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
a=double
b=timestamp
c=nvarchar
```

- “VLENGTH Function” on page 1258
- “VNAME Function” on page 1260

WEEK Function

Returns the week-number value.

Category: Date and Time

Returned data type: DOUBLE

Syntax

WEEK([*sas-date*], ['*descriptor*'])

Optional Arguments

sas-date
specifies the SAS date value. If the *sas-date* argument is not specified, the WEEK function returns the week-number value of the current date.

Data type DOUBLE

descriptor
specifies the value of the descriptor. The following descriptors can be specified in uppercase or lowercase characters.

U
specifies the number-of-the-week within the year. Sunday is considered the first day of the week. The number-of-the-week value is represented as a decimal number in the range 0–53. Week 53 has no special meaning. The value of `week('31dec2013'd, 'u')` is 53. U is the default value.

Tip The U and W descriptors are similar, except that the U descriptor considers Sunday as the first day of the week, and the W descriptor considers Monday as the first day of the week.

See "The U Descriptor" on page 1270

V

specifies the number-of-the-week whose value is represented as a decimal number in the range 1–53. Monday is considered the first day of the week and week 1 of the year is the week that includes both January 4 and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year.

See "The V Descriptor" on page 1271

W

specifies the number-of-the-week within the year. Monday is considered the first day of the week. The number-of-the-week value is represented as a decimal number in the range 0–53. Week 53 has no special meaning. The value of `week('31dec2013'd, 'w')` is 53.

Tip The U and W descriptors are similar except that the U descriptor considers Sunday as the first day of the week, and the W descriptor considers Monday as the first day of the week.

See "The W Descriptor" on page 1271

Default U

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Note If you specify a descriptor other than U, V, or W, a note is written to the SAS log to indicate that the argument is invalid. The function returns NULL.

Details

The Basics

The WEEK function reads a SAS date value and returns the week number. The WEEK function is not dependent on locale, and uses only the Gregorian calendar in its computations.

The U Descriptor

The WEEK function with the U descriptor reads a SAS date value and returns the number of the week within the year. The number-of-the-week value is represented as a decimal number in the range 0–53, with a leading zero and maximum value of 53. Week 0 means that the first day of the week occurs in the preceding year. The fifth week of the year is represented as 05.

Sunday is considered the first day of the week. For example, the value of `week('01jan2013'd, 'u')` is 0.

The V Descriptor

The WEEK function with the V descriptor reads a SAS date value and returns the week number. The number-of-the-week is represented as a decimal number in the range 01–53. The decimal number has a leading zero and a maximum value of 53. Weeks begin on a Monday, and week 1 of the year is the week that includes both January 4 and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year. In the following example, 01jan2014 and 31dec2013 occur in the same week. The first day (Monday) of that week is 30dec2013. Therefore, `week('01jan2014'd, 'v')` and `week('30dec2013'd, 'v')` both return a value of 53. This means that both dates occur in week 53 of the year 2013.

The W Descriptor

The WEEK function with the W descriptor reads a SAS date value and returns the number of the week within the year. The number-of-the-week value is represented as a decimal number in the range 0–53, with a leading zero and maximum value of 53. Week 0 means that the first day of the week occurs in the preceding year. The fifth week of the year would be represented as 05.

Monday is considered the first day of the week. Therefore, the value of `week('30dec2013'd, 'w')` is 1.

Comparisons of Descriptors

U is the default descriptor. Its range is 0-53, and the first day of the week is Sunday. The V descriptor has a range of 1-53 and the first day of the week is Monday. The W descriptor has a range of 0-53 and the first day of the week is Monday.

The following list describes the descriptors and an associated week:

- Week 0:

  U indicates the days in the current Gregorian year before week 1.

  V does not apply.

  W indicates the days in the current Gregorian year before week 1.

- Week 1:

  U begins on the first Sunday in a Gregorian year.

  V begins on the Monday between December 29 of the previous Gregorian year and January 4 of the current Gregorian year. The first ISO week can span the previous and current Gregorian years.

  W begins on the first Monday in a Gregorian year.

- End of Year Weeks:

  U specifies that the last week (52 or 53) in the year can contain less than 7 days. A Sunday to Saturday period that spans 2 consecutive Gregorian years is designated as 52 and 0 or 53 and 0.

V specifies that the last week (52 or 53) of the ISO year contains 7 days. However, the last week of the ISO year can span the current Gregorian and next Gregorian year.

W specifies that the last week (52 or 53) in the year can contain less than 7 days. A Monday to Sunday period that spans two consecutive Gregorian years is designated as 52 and 0 or 53 and 0.

Example

The following program shows the values of the U, V, and W descriptors for the date March 1, 2019.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double sasdate x y z;
   method run();
      sasdate=to_double(date'2019-03-01');
      x=week(sasdate, 'u');
      y=week(sasdate, 'v');
      z=week(sasdate, 'w');
      put x;
      put y;
      put z;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
8
9
8
```

WEEKDAY Function

From a SAS date value, returns a whole number that corresponds to the day of the week.

Category: Date and Time

Returned data type: DOUBLE

Syntax

WEEKDAY(*expression*)

Required Argument

expression
specifies any valid expression that represents a SAS date value.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The WEEKDAY function produces a whole number that represents the day of the week, where 1 = Sunday, 2 = Monday, ..., 7 = Saturday.

For information about how DS2 handles date and time values, see "DS2 Expressions" in *SAS DS2 Programmer's Guide*.

Example

The following program illustrates the WEEKDAY function when the current day is Sunday:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double sasdate x;
   method run();
      sasdate=to_double(date'2019-02-24');
      x=weekday(sasdate);
```

```
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
1
```

WHICHC Function

Returns the first position of a character string from a list of character strings.

Category: Character

Returned data type: DOUBLE

Syntax

WHICHC(*search-expression*, *expression-list-item-1*, *expression-list-item-2* [, ...*expression-list-item-n*])

Required Arguments

search-expression
specifies any valid expression that evaluates or can be coerced to a character string that is compared with a list of character string expressions.

Requirement: Literal character strings must be enclosed in single quotation marks.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression-list-item
specifies any valid expression that evaluates or can be coerced to a character string and that is a member of a list of character string expressions.

Requirements: Literal character strings must be enclosed in single quotation marks.

At least two expressions are required in the list.

Data type: CHAR, NCHAR, NVARCHAR, VARCHAR

See: "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The WHICHC function searches the character expression list, from left to right, for the first expression that matches the search expression. If a match is found, WHICHC returns its position in the expression list. If none of the expressions match the search expression, WHICHC returns a value of 0.

Example

In the following program, 'Spain' appears twice in the list. The WHICHC function returns the first position of 'Spain' in the list:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double position;
   method run();
      position=whichc('Spain', 'Denmark', 'Germany', 'Austria','Spain',
         'China', 'Egypt', 'Spain', 'France');
      put position;
   end;
run;
quit;
```

SAS writes the following output to the log:

```
4
```

See Also

Functions:

- "WHICHN Function" on page 1275

WHICHN Function

Returns the first position of a number from a list of numbers.

Category:	Mathematical
Returned data type:	DOUBLE

Syntax

WHICHN(*search-expression*, *expression-list-item-1*, *expression-list-item-2* [, ...*expression-list-item-n*])

Required Arguments

search-expression
specifies any valid expression that evaluates to a number and that is compared with a list of numeric expressions.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

expression-list-item
specifies any valid expression that evaluates to a number and is part of a list.

Requirement At least two expressions are required in the list.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The WHICHN function searches the numeric expression list, from left to right, for the first expression that matches the search expression. If a match is found, WHICHN returns its position in the expression list. If none of the expressions match the search expression, WHICHN returns a value of 0. Arguments for the WHICHN functions can be any numeric data type.

Example

In the following program, 4.5 appears two times in the list. The WHICHN function returns the first position of 4.5 in the list.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double position;
   method run();
      position=whichn(4.5,7.3, 8.6, 4.5, 4.5, 2.1, 6.4);
      put position;
   end;
run;
quit;
```

SAS writes the following output to the log:

```
3
```

See Also

Functions:

- "WHICHC Function" on page 1274

YEAR Function

Returns the year from a SAS date value.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

YEAR(*date*)

Required Argument

date
specifies any valid expression that represents a SAS date value.

Data type	DOUBLE
See	"DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The YEAR function produces a four-digit numeric value that represents the year.

Example

The following program illustrates the YEAR function when the year is the current year.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double x thdate;
   method run();
      thdate=today();
      x=year(thdate);
      put x;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
2019
```

See Also

- "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Functions:

- "DAY Function" on page 505
- "MONTH Function" on page 873

YIELDP Function

Returns the yield-to-maturity for a periodic cash flow stream, such as a bond.

Category: Financial

Returned data type: DOUBLE

Syntax

YIELDP(*A*, *c*, *n*, *K*, k_0, *p*)

Required Arguments

A
specifies the face value.

Ranges $A > 0$

$A > 0$

Data type DOUBLE

c

specifies the nominal annual coupon rate, expressed as a fraction.

Ranges $0 \leq c < 1$

$0 \leq c < 1$

Data type DOUBLE

n

specifies the number of coupons per year.

Ranges $n > 0$

$n > 0$

Data type DOUBLE

K

specifies the number of remaining coupons from settlement date to maturity.

Ranges $K > 0$

$K > 0$

Data type DOUBLE

k_0

specifies the time from settlement date to the next coupon as a fraction of the annual basis.

Ranges $0 < k_0 \leq \frac{1}{n}$

$0 < k_0 \leq 1/n$

Data type DOUBLE

p

specifies the price with accrued interest.

Ranges $p > 0$

$p > 0$

Data type DOUBLE

Details

The YIELDP function is based on the following relationship:

$$P = \sum_{k=1}^{K} c(k) \frac{1}{\left(1 + \frac{y}{n}\right)^{t_k}}$$

The following relationships apply to the preceding equation:

- $t_k = nk_0 + k - 1$
- $c(k) = \frac{c}{n}A \quad for\ k = 1, \ldots, K-1$
- $c(K) = \left(1 + \frac{c}{n}\right)A$

The YIELDP function solves for *y*.

Example

In the following program, the YIELDP function returns the yield-to-maturity of a bond that has a face value of 1000, an annual coupon rate of 0.01, 4 coupons per year, and 14 remaining coupons. The time from settlement date to next coupon date is 0.165, and the price with accrued interest is 800.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double y;
   method run();
      y=yieldp(1000,.01,4,14,.165,800);
      put y;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
0.0775031247735
```

YRDIF Function

Returns the difference in years between two dates according to specified day count conventions; returns a person's age.

Category: Date and Time

Returned data type: DOUBLE

Syntax

YRDIF(*start-date*, *end-date*[, *basis*])

Required Arguments

start-date
specifies a SAS date value that identifies the starting date.

Data type DOUBLE

end-date
specifies a SAS date value that identifies the ending date.

Data type DOUBLE

Optional Argument

basis
identifies a character constant or variable that describes how SAS calculates a date difference or a person's age. The following character strings are valid: '30/360' (a 30-day month and a 360-day year), 'ACT/ACT', 'ACT/360', 'ACT/365', and 'AGE'. For example, 'ACT/360' uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 360, regardless of the actual number of days in each year. For additional information, see SAS DS2 Language Reference.

identifies a character constant or variable that describes how SAS calculates a date difference or a person's age. The following character strings are valid:

'30/360'
specifies a 30-day month and a 360-day year in calculating the number of years. Each month is considered to have 30 days, and each year 360 days, regardless of the actual number of days in each month or year.

Alias '360'

Tip If either date falls at the end of a month, it is treated as if it were the last day of a 30-day month.

'ACT/ACT'
uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days that fall in 365-day years divided by 365 plus the number of days that fall in 366-day years divided by 366.

Alias 'Actual'

'ACT/360'
uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 360, regardless of the actual number of days in each year.

'ACT/365'
uses the actual number of days between dates in calculating the number of years. SAS calculates this value as the number of days divided by 365, regardless of the actual number of days in each year.

'AGE'
specifies that a person's age will be computed.

If you do not specify a third argument, AGE becomes the default value for *basis*.

Data type CHAR, NCHAR, NVARCHAR, VARCHAR

Details

Using YRDIF in Financial Applications

The Basics

The YRDIF function can be used in calculating interest for fixed income securities when the third argument, *basis*, is present. YRDIF returns the difference between two dates according to specified day count conventions.

Calculations That Use ACT/ACT Basis

In YRDIF calculations that use the *ACT/ACT* basis, both a 365-day year and 366-day year are taken into account. For example, if n365 equals the number of days between the start and end dates in a 365-day year, and n366 equals the number of days between the start and end dates in a 366-day year, the YRDIF calculation is computed as YRDIF=n365/365.0 + n366/366.0. This calculation corresponds to the commonly understood *ACT/ACT* day count basis that is documented in the financial literature. The values for *basis* also include *30/360*, *ACT/360*, and *ACT/365*. Each has well-defined meanings that must be conformed to in calculating interest payments for specific financial instruments.

Computing a Person's Age

The YRDIF function can compute a person's age. The first two arguments, *start-date* and *end-date*, are required. If the value of *basis* is AGE, then YRDIF computes the age. The age computation takes into account leap years. No other values for *basis* are valid when computing a person's age.

Examples

Example 1: Calculating a Difference in Years Based on Basis

In the following program, YRDIF returns the difference in years between two dates based on each of the options for *basis*.

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data test(overwrite=yes);
   dcl double sdate edate y30360 yactact yact360 yact365;
   method run();
      sdate= to_double(date'1998-10-16');
      edate= to_double(date'2010-02-06');
      y30360=yrdif(sdate, edate, '30/360');
      yactact=yrdif(sdate, edate, 'ACT/ACT');
      yact360=yrdif(sdate, edate, 'ACT/360');
      yact365=yrdif(sdate, edate, 'ACT/365');
      put y30360=;
      put yactact=;
      put yact360=;
      put yact365=;
   end;
enddata;
run;
quit;
```

SAS writes the following results to the log:

```
y30360=11.3055555555555
yactact=11.3095890410958
yact360=11.475
yact365=11.317808219178
```

Example 2: Calculating a Person's Age

You can calculate a person's age by using three arguments in the YRDIF function. The third argument, *basis*, must have a value of AGE:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
data _null_;
   dcl double sdate edate age;
   method run();
      sdate= to_double(date'1998-10-16');
      edate= to_double(date'2010-02-16');
      age=yrdif(sdate, edate, 'AGE');
      put age= 'years';
   end;
enddata;
run;
```

```
quit;
```

SAS writes the following results to the log:

```
age=11.3369863013698 years
```

YYQ Function

Returns a SAS date value from year and quarter year values.

Category:	Date and Time
Returned data type:	DOUBLE

Syntax

YYQ(*year*, *quarter*)

Required Arguments

year
specifies any valid expression that evaluates to a two-digit or four-digit whole number that represents the year.

Interaction The YEARCUTOFF= system option defines the year value for two-digit dates.

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

quarter
specifies the quarter of the year (1, 2, 3, or 4).

Data type DOUBLE

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The YYQ function returns a SAS date value that corresponds to the first day of the specified quarter. If either *year* or *quarter* is null or missing, or if the quarter value is not valid, the result is a null or missing value.

Example

The following programs illustrate the YYQ function:

Note: In this example, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
   data test(overwrite=yes);
   dcl double DateValue Date7Value Date9Value;
   method run();
      DateValue=yyq(2019,3);
      put DateValue;
      put DateValue date7.;
      put DateValue date9.;
   end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
21731
01JUL19
01JUL2019
```

```
proc ds2;
data test(overwrite=yes);
   dcl double StartOfQuarter;
   method run();
```

```
        StartOfQuarter=yyq(2019,4);
        put StartOfQuarter;
        put StartOfQuarter date9.;
    end;
enddata;
run;
quit;
```

SAS writes the following output to the log:

```
21823
01OCT2019
```

- "YEAR Function" on page 1277

ZIPCITY Function

Returns a city name and the two-character postal code that corresponds to a ZIP code.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR

Syntax

ZIPCITY(*ZIP-code*)

Required Argument

ZIP-code
specifies a numeric or character expression that contains a five-digit ZIP code.

Data type DOUBLE, CHAR(n)

Tip If the value of *ZIP-code* begins with leading zeros, you can enter the value without the leading zeros. For example, if you enter 1040, ZIPCITY assumes that the value is 01040.

Details

The Basics

ZIPCITY returns a city name and the two-character postal code that corresponds to its five-digit ZIP code argument. ZIPCITY returns the character values in mixed-case.

If the ZIP code is unknown, ZIPCITY returns a blank value. If the ZIPCITY function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

Note: The Sashelp.Zipcode data set must be present when you use this function. If you remove the data set, ZIPCITY returns unexpected results.

How the ZIP Code Is Translated to the State Postal Code

To determine which state corresponds to a particular ZIP code, this function uses a zone table that consists of the start and end ZIP code values for each state. The function then finds the corresponding state for that range of ZIP codes. The start and end ZIP code values for each state allow for exceptions.

With very few exceptions, a zone does not span multiple states. The exceptions are included in the zone table. It is possible for new zones or new exceptions to be added by the U.S. Postal Service at any time. However, SAS software is updated only with each new release of the product.

Determining When the State Postal Code Table Was Last Updated

The Sashelp.Zipcode data set contains postal code information that is used with ZIPCITY and other ZIP code functions. To determine when this data set was last updated, execute PROC CONTENTS:

```
proc contents data=sashelp.zipcode;
run;
```

Output from the CONTENTS procedure provides the date of the last update, along with the contents of the Sashelp.Zipcode data set.

Note: You can download the latest version of the Sashelp.Zipcode file from the Technical Support Web site. Select **Zipcode Data Set** from the Name column to begin the download process. You must execute the CIMPORT procedure after you download and unzip the data set.

If you use an invalid ZIP code (one that is not found in the Sashelp.Zipcode data set), SAS returns a message that indicates there is an invalid argument in the ZIPCITY function.

Comparisons

The ZIPCITY, ZIPNAME, ZIPNAMEL, and ZIPSTATE functions accept the same argument but return different values:

- ZIPCITY returns the name of the city in mixed-case and the two-character postal code that corresponds to its five-digit ZIP code argument.
- ZIPNAME returns the uppercase name of the state or U.S. territory that corresponds to its five-digit ZIP code argument.
- ZIPNAMEL returns the mixed-case name of the state or U.S. territory that corresponds to its five-digit ZIP code argument.
- ZIPSTATE returns the uppercase two-character state postal code (or worldwide GSA geographic code for U.S. territories) that corresponds to its five-digit ZIP code argument.

Example

This example returns a city name and the two-character state postal code that corresponds to a ZIP code.

```
proc ds2;
 data _null_;
   method run();
   dcl char(50) city;
   city=zipcity(27513);
   put city;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
Cary, NC
```

Functions:

- “ZIPCITYDISTANCE Function” on page 1289
- “ZIPFIPS Function” on page 1290
- “ZIPNAME Function” on page 1292

- "ZIPNAMEL Function" on page 1294
- "ZIPSTATE Function" on page 1295

ZIPCITYDISTANCE Function

Returns the geodetic distance between two ZIP code locations.

Categories: Distance
State and ZIP code

Alias: ZIPCITYDIST

Restriction: This function is not supported on the CAS server.

Returned data type: DOUBLE

Syntax

ZIPCITYDISTANCE(*ZIP-code-1*, *ZIP-code-2*)

Required Argument

ZIP-code
specifies a numeric or character expression that contains the ZIP code of a location in the United States of America.

Data type CHAR(n), DOUBLE

Details

The ZIPCITYDISTANCE function returns the geodetic distance in miles between two ZIP code locations. The centroid of each ZIP code is used in the calculation.

The Sashelp.Zipcode data set must be present when you use this function. If you remove the data set, then ZIPCITYDISTANCE returns unexpected results.

The Sashelp.Zipcode data set contains postal code information that is used with ZIPCITYDISTANCE and other ZIP code functions. To determine when this data set was last updated, execute PROC CONTENTS:

```
proc contents data=sashelp.zipcode;
run;
```

Output from the CONTENTS procedure provides the date of the last update, along with the contents of the SASHELP.ZIPCODE data set.

Note: You can download the latest version of the Sashelp.Zipcode file from the SAS external website. The file is located at the Technical Support Web site. Select **Zipcode Data Set** from the **Name** column to begin the download process. You must execute the CIMPORT procedure after you download and unzip the data set. See Updating Zipcode Data Set for more information.

If you use an invalid ZIP code (one that is not found in the Sashelp.Zipcode data set), then SAS returns a message that indicates that there is an invalid argument in the ZIPCITYDISTANCE function.

Example

In the following example, the first ZIP code identifies a location in San Francisco, CA, and the second ZIP code identifies a location in Bangor, ME. ZIPCITYDISTANCE returns the distance in miles between these two locations.

```
proc ds2;
 data _null_;
   method run();
   dcl double dist;
   dist=zipcitydist(94103, 04401);
   put 'Miles between San Francisco, CA, to Bangor, ME: ' dist;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
Miles between San Francisco, CA, to Bangor, ME:  2782.3
```

Functions:

- “ZIPCITY Function” on page 1286

ZIPFIPS Function

Converts ZIP codes to two-digit FIPS codes.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	DOUBLE

Syntax

ZIPFIPS(*ZIP-code*)

Required Argument

ZIP-code
specifies a numeric or character expression that contains a five-digit ZIP code.

Data type CHAR(n), DOUBLE

Tip If the value of *ZIP-code* begins with leading zeros, you can enter the value without the leading zeros. For example, if you enter 1040, ZIPFIPS assumes that the value is 01040.

Details

The Basics

The ZIPFIPS function returns the two-digit numeric U.S. Federal Information Processing Standards (FIPS) code that corresponds to its five-digit ZIP code argument.

Example

This example converts the ZIP code for Cary, NC, to a two-digit FIPS code:

```
proc ds2;
 data _null_;
   method run();
   dcl double statefips;
   statefips=zipfips(27511);
   put statefips=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
statefips=37
```

Functions:

- “ZIPCITY Function” on page 1286

ZIPNAME Function

Converts ZIP codes to uppercase state names.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR

Syntax

ZIPNAME(*ZIP-code*)

Required Argument

ZIP-code
specifies a numeric or character expression that contains a five-digit ZIP code.

Data type	CHAR(n), DOUBLE
Tip	If the value of *ZIP-code* begins with leading zeros, you can enter the value without the leading zeros. For example, if you enter 1040, ZIPNAME assumes that the value is 01040.

Details

The Basics

ZIPNAME returns the name of the state or U.S. territory that corresponds to its five-digit ZIP code argument. ZIPNAME returns character values up to 20 characters long, all in uppercase.

If the ZIPNAME function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

How the ZIP Code Is Translated to the State Postal Code

To determine which state corresponds to a particular ZIP code, this function uses a zone table that consists of the start and end ZIP code values for each state. The

function then finds the corresponding state for that range of ZIP codes. The start and end ZIP code values for each state allow for exceptions.

With very few exceptions, a zone does not span multiple states. The exceptions are included in the zone table. It is possible for new zones or new exceptions to be added by the U.S. Postal Service at any time. However, SAS software is updated only with each new release of the product.

Comparisons

The ZIPNAME and ZIPNAMEL functions both accept a postal ZIP code and return a state name. ZIPNAME returns the uppercase name of the state or U.S. territory that corresponds to its five-digit ZIP code argument. ZIPNAMEL returns the mixed-case name of the state or U.S. territory that corresponds to its five-digit ZIP code argument.

Example

This example shows the difference between ZIPNAME and ZIPNAMEL.

```
proc ds2;
 data _null_;
   method run();
   dcl char(15) state;
   state=zipname(27511);
   put state=;
   state=zipnamel(27511);
   put state=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
state=NORTH CAROLINA
state=North Carolina
```

- “ZIPNAMEL Function” on page 1294
- “ZIPSTATE Function” on page 1295

ZIPNAMEL Function

Converts ZIP codes to mixed-case state names.

Category: State and ZIP code

Restriction: This function is not supported on the CAS server.

Returned data type: CHAR

Syntax

ZIPNAMEL(*ZIP-code*)

Required Argument

ZIP-code
specifies a numeric or character expression that contains a five-digit ZIP code.

Data type CHAR(n), DOUBLE

Tip If the value of *ZIP-code* begins with leading zeros, you can enter the value without the leading zeros. For example, if you enter 1040, ZIPNAMEL assumes that the value is 01040.

Details

The Basics

If the ZIPNAMEL function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

ZIPNAMEL returns the name of the state or U.S. territory that corresponds to its five-digit ZIP code argument. ZIPNAMEL returns mixed-case character values up to 20 characters long.

How the ZIP Code Is Translated to the State Postal Code

To determine which state corresponds to a particular ZIP code, this function uses a zone table that consists of the start and end ZIP code values for each state. The function then finds the corresponding state for that range of ZIP codes. The start and end ZIP code values for each state allow for exceptions.

With very few exceptions, a zone does not span multiple states. The exceptions are included in the zone table. It is possible for new zones or new exceptions to be

added by the U.S. Postal Service at any time. However, SAS software is updated only with each new release of the product.

Example

This example converts the postal zip code for Cary, NC to a mixed-case state name.

```
proc ds2;
 data _null_;
   method run();
   dcl char(15) state;
   state=zipnamel(27511);
   put state=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
state=North Carolina
```

See Also

Functions:

- “ZIPCITY Function” on page 1286
- “ZIPFIPS Function” on page 1290
- “ZIPNAME Function” on page 1292
- “ZIPSTATE Function” on page 1295

ZIPSTATE Function

Converts ZIP codes to two-character state postal codes.

Category:	State and ZIP code
Restriction:	This function is not supported on the CAS server.
Returned data type:	CHAR(2)

Syntax

ZIPSTATE(*ZIP-code*)

Required Argument

ZIP-code
specifies a numeric or character expression that contains a valid five-digit ZIP code.

Tip If the value of *ZIP-code* begins with leading zeros, you can enter the value without the leading zeros. For example, if you enter 1040, ZIPSTATE assumes that the value is 01040.

Details

The Basics

If the ZIPSTATE function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 20.

ZIPSTATE returns the two-character state postal code (or worldwide GSA geographic code for U.S. territories) that corresponds to its five-digit ZIP code argument. ZIPSTATE returns character values in uppercase.

Note: ZIPSTATE does not validate the ZIP code.

How the ZIP Code Is Converted to the State Postal Code

To determine which state corresponds to a particular ZIP code, this function uses a zone table that consists of the start and end ZIP code values for each state. The function then finds the corresponding state for that range of ZIP codes. The zone table does not validate ZIP code values.

Typically, a zone does not span multiple states. Exceptions are included in the zone table. It is possible for new zones or new exceptions to be added by the U.S. Postal Service at any time. However, SAS software is updated only with each new release of the product.

Army Post Office (APO) and Fleet Post Office (FPO) Postal Codes

The ZIPSTATE function recognizes APO and FPO ZIP codes. These military ZIP codes correspond to their exit bases in the United States. The ZIP codes are contained in the Sashelp.Zipmil data set. To determine when this data set was last updated, execute PROC CONTENTS:

```
proc contents data=sashelp.zipmil;
run;
```

Output from the CONTENTS procedure provides the date of the last update and the contents of the Sashelp.Zipmil data set.

Note: You can download the latest version of the Sashelp.Zipmil data set from the Technical Support website. Select **Zipcode Data Set** from the Name column to begin the download process. You must execute the CIMPORT procedure after you download and unzip the data set.

Determining When the State Postal Code Table Was Last Updated

Except for APO and FPO addresses, the Sashelp.Zipcode data set contains postal code information that is used with ZIPSTATE and other ZIP code functions. To determine when this data set was last updated, execute PROC CONTENTS:

```
proc contents data=sashelp.zipcode;
run;
```

Output from the CONTENTS procedure provides the date of the last update and the contents of the Sashelp.Zipcode data set.

Note: You can download the latest version of the Sashelp.Zipcode data set from the Technical Support website. Select **Zipcode Data Set** from the Name column to begin the download process. You must execute the CIMPORT procedure after you download and unzip the data set.

Comparisons

ZIPSTATE returns the uppercase two-character state postal code (or worldwide GSA geographic code for U.S. territories) that corresponds to a five-digit ZIP code argument. ZIPFIPS returns the two-digit FIPS code that corresponds to a US ZIP code.

Example: ZIPSTATE Function

This example converts the ZIP code for the state of North Carolina to a state postal code.

```
proc ds2;
 data _null_;
   method run();
   dcl char(2) state;
   state=zipstate(27511);
   put state=;
   end;
 enddata;
run;
quit;
```

These statements produce this result:

```
state=NC
```

DS2 Informats

Overview of Informats

An **informat** is an instruction that determines how values are read into a column. For example, the following value contains a dollar sign and commas:

```
$1,000,000
```

To remove the dollar sign ($) and commas (,) before storing the numeric value 1000000 in a column, read this value with the COMMA11. informat.

General Informat Syntax

DS2 informats have the following form:

[$] *informat* [*w*] . [*d*]

Here is an explanation of the syntax:

$
indicates a character informat; its absence indicates a numeric informat.

informat
names the informat. The informat is a SAS informat or a user-defined informat that was previously defined with the INVALUE statement in PROC FORMAT. For more information about user-defined informats, see PROC FORMAT in the *Base SAS Procedures Guide*.

w
specifies the informat width, which for most informats is the number of columns in the input data.

d
specifies an optional decimal scaling factor in the numeric informats. SAS divides the input data by 10 to the power of *d*.

Note: Even though SAS can read up to 32 decimal places when you specify some numeric informats, floating-point numbers with more than 15 decimal places might lose precision due to the limitations of the eight-byte floating-point representation used by most computers.

Informats always contain a period (.) as a part of the name. If you omit the *w* and the *d* values from the informat, SAS uses default values. If the data contains decimal points, SAS ignores the *d* value and reads the number of decimal places that are actually in the input data.

For more information about how informats work and a complete list of informats, see the *SAS Formats and Informats: Reference*.

How Informats Are Used in DS2

DS2 supports SAS informats as follows.

- Both informats supplied by SAS and user-defined informats can be associated with a column. For information about how to create your own informat in SAS, see PROC FORMAT in the *Base SAS Procedures Guide*.

  Note: To create and access user-defined informats, a SAS session must be available in order to access the SAS catalog file that stores the SAS informat definitions.

- Only the SAS data set and SPD data sets support storing and retrieving an informat with a column.
- Informats can be associated with all data types, but all data types are converted to either CHAR or DOUBLE.
- You can associate SAS informats with a column by using the HAVING clause of the DS2 DECLARE statement. For more information, see "How to Specify Informats in DS2" on page 1301.

For more information and a complete list of informats supplied by SAS, see the section on informats in the *SAS Formats and Informats: Reference*.

How to Specify Informats in DS2

In DS2, specify informats as an attribute in the HAVING clause of the DECLARE statement. For example, in the following statement, the column *y* is declared with the IEEE8.2 format and the BITS5.2 informat.

```
dcl double y having format ieee8.2 informat bits5.2;
```

Note: In DS2, an informat for a column cannot be changed or removed.

Validation of DS2 Informats

Informats are not validated by a data source or applied to a column until execution time.

When metadata for a column is requested, the informat name is returned without validation.

DS2 Informat Examples

```
dcl char(10) y having label 'varchar' format $5. informat
$charzb4.3;

dcl double ssn having format best 10.4 informat comma10.4;

dcl double(6) salary having informat uscurrency.;

dcl char(12) site having informat $city.;
```

9

DS2 Operators

Dictionary

NEW Operator

Constructs an instance of a package.

Notes: See "Operators in Expressions " for information on operators in expressions.

The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

See: The _NEW_ operator for predefined DS2 packages is documented in the reference section for each package.

Syntax

package-variable=**_NEW_** *package-name* ([*constructor-arguments*]);

Required Arguments

package-variable
specifies a name that can reference an instance of the package.

package-name
specifies the name of the package.

Requirement *package-name* must be a DS2 predefined package type or created with a PACKAGE statement before the _NEW_ operator is executed.

Optional Argument

constructor-arguments
specifies any constructor arguments that are passed to the constructor of the package instance.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

After you have stored methods and variables in a package by using the PACKAGE statement, you can access them by declaring and instantiating the package. If you use the _NEW_ operator to instantiate the package, you must first use the DECLARE PACKAGE statement to declare the package variable.

declare package *package-name variable-name*;

variable-name = _new_ *package-name*( );

For example, in the following lines of code, the DECLARE PACKAGE statement tells SAS that C is a variable of type COMPLEX package. The _NEW_ operator constructs an instance of the COMPLEX package and assigns it to the package variable C.

```
declare package complex c;
c = _new_ complex();
```

If you want to initialize package data, you can use a constructor. A constructor is a method that is used to instantiate a package and to initialize the package data. For example, you can provide initialization data by using parameters in the constructor syntax for the hash and hash iterator package

```
declare package hash h();
h = _new_ hash(0, 'mytable', 'yes', 'replace', 'sumnum', 'y');
```

Note: You can use the DECLARE PACKAGE statement with constructor arguments to declare and instantiate a package in one step. The example shown above would look like this.

```
declare package hash h(0, 'mytable', 'yes', 'replace', 'sumnum', 'y');
```

For more information, see "DS2 Packages" in *SAS DS2 Programmer's Guide* and "DECLARE PACKAGE Statement" on page 1338.

Comparisons

You can use the DECLARE PACKAGE statement and the _NEW_ operator, or the DECLARE PACKAGE statement alone to declare and instantiate an instance of a package.

Example

See "User-Defined Packages" in *SAS DS2 Programmer's Guide* and "Predefined DS2 Packages" in *SAS DS2 Programmer's Guide*.

10

DS2 Statements

Overview of Statements

A DS2 statement is a series of items that can include keywords, identifiers, special characters, and operators. A DS2 statement can perform the following actions:

- perform variable assignments
- influence program control
- perform input and output of data
- create methods
- call methods and functions
- specify or change the behavior of a DS2 program

All DS2 statements end with a semicolon.

Here are the statement categories:

Behavior
: use to specify or change the behavior of a DS2 program.

Block
: use to create a programming blocks. For more information, see "Programming Blocks" in *SAS DS2 Programmer's Guide*.

Block control
: use to modify program behavior in a programming block.

Global
: use anywhere in the global section of a programming block created by a DATA, PACKAGE, or THREAD statement.

Local
: use only inside a DS2 method.

Note that some statements belong to multiple categories. For example, the DECLARE statement can be both a global and a local statement.

Block Statements

Overview of Block Statements

There are five DS2 statements that differ from other statements in that they are used to group other statements in programming blocks. The block statements are as follows.

- DO...END
- METHOD...END
- PACKAGE...ENDPACKAGE
- DATA...ENDDATA
- THREAD...ENDTHREAD

Block statements can be divided further into two categories: statements that create program blocks and statements that create program subblocks. Program block statements include PACKAGE...ENDPACKGE, DATA...ENDDATA, and THREAD...ENDTHREAD. Program subblock statements include METHOD...END and DO...END.

In this documentation, these terms are used for programming blocks.

- A data programming block or **data program** refers to code bounded by DATA... ENDDATA statements.
- A package programming block or **package** refers to the stored library of variables and methods bounded by PACKAGE...ENDPACKAGE statements. The variables and methods of a package can be used by DS2 programs, threads, or other packages.
- A thread programming block, or **thread program**, refers to a stored program bounded by THREAD...ENDTHREAD statements. The thread program can be called by the SET FROM statement in a DS2 program or package.
- A DO programming block, or **DO loop**, refers to a subblock of programming statements bounded by DO...END statements.
- A method programming block or **method block** refers to a subblock of programming statements bounded by METHOD...END statements.

Each data program must have one and only one program block statement. A data program can and often has multiple subblock statements. For more information about programming blocks, see “Programming Blocks” in *SAS DS2 Programmer’s Guide*.

Program Block Statements

Program blocks are created with the DATA, PACKAGE, and THREAD statements. These statements, and their concluding END statements, are used outside of any other statement, and the program blocks that they define can contain other statements. All other statements must be used inside one of these blocks.

A data program , a package, or a thread program contains two sections: a section of global declarations followed by a section of METHOD statements. This is an example of a data program.

```
data t;
   ...global declarations
   ...METHOD statement;
enddata;
```

All global declarations must precede the first METHOD statement in the program. A syntax error results if a global declaration is found after a METHOD statement in a program.

The DATA statement creates a data program. A data program consists of the global declaration list and the METHOD statement list contained within a program created by the DATA...ENDDATA statements. For information about compiling and executing a data program, see "DS2 Procedure" in *Base SAS Procedures Guide*. For more information about the DATA statement, see the "DATA Statement" on page 1325.

A thread program is created by the THREAD...ENDTHREAD statements. A thread program consists of the global declaration list and the METHOD statement list contained within the THREAD...ENDTHREAD statements. The structure of a thread program is essentially the same as that of a data program, but is used to execute several threads in parallel. When you use a DECLARE statement in another data program or package to reference the thread, the thread program is loaded into memory. You can then use the SET FROM statement in a subsequent data program to run the program in one or more operating system threads. For more information, see the "THREAD Statement" on page 1444.

The package is defined by the PACKAGE...ENDPACKAGE statements. A package is a collection of variables and methods that can be called by a data program, a thread program, or another package. A package consists of the global declaration list and the METHOD statement list contained within a programming block created by the PACKAGE...ENDPACKAGE statements. A package is compiled and stored for later use. When you declare the package in a DS2 program, a thread program or another package, the stored package is loaded into memory. You can then access the methods and variables in the package. For more information, see the "PACKAGE Statement" on page 1406.

Program Subblock Statements

Program subblock statements are created with the METHOD or DO statements. A DS2 program normally contains several subblocks of programming statements.

Each subblock contains two sections: a section of global declaration statements followed by a section of other local statements. This is an example of a METHOD subblock.

```
method m;
   ...global declarations
   ...local statements;
end;
```

All global declaration statements must precede all other local statements in the subblock. A syntax error will result if a global declaration statement is placed after any other type of statement in a programming subblock.

Global Declaration Statements

Global declaration statements are statements that must be in the declaration section of a program created by a DATA, PACKAGE, or THREAD statement. Global declaration statements generally provide information for your DS2 program or request information or data. Generally, global declaration statements are not executable; they take effect as soon as DS2 compiles program statements.

The following table lists DS2 statements that are allowed in the declaration section of a DS2 program.

Note: The DECLARE statement can be used both globally and within a method.

- DECLARE
- DROP
- FORWARD
- KEEP
- RENAME
- RETAIN
- VARARRAY
- VARLIST

Local Statements

Local statements are statements that you can use inside a programming block created with a METHOD statement.

The following table lists DS2 method statements.

Note: All global declaration statements must proceed all other local statements in a method programming block.

Note: A METHOD statement is not a local statement. Therefore, a METHOD statement cannot be nested inside another METHOD statement.

- Assignment
- BY
- CONTINUE
- DECLARE
- DECLARE PACKAGE
- DECLARE THREAD
- DO
- GOTO
- IF, Subsetting
- IF-THEN/ELSE
- Labels
- LEAVE
- MERGE
- Null
- OUTPUT
- PUT
- RETURN
- SELECT
- SET
- SET FROM
- STOP
- Sum

Including Comments in a DS2 Program

You might want to include comments in a DS2 program to document the purpose of the program.

The DS2 language supports the following syntax for including comments in DS2 code:

```
/*comment*/
```

A DS2 comment has the following characteristics:

- It can be added anywhere in the DS2 program where a single blank space can appear, except in character constants or delimited identifiers.
- It can be any length.
- It can be embedded in DS2 statements and DS2 expressions.
- It can contain internal white space, newlines, semicolons, and quotation marks, including unmatched quotation marks.
- It is supported in all environments in which DS2 can be run.
- It *cannot* be nested.

The SAS macro comment syntax *%*comment;* is not supported by the DS2 compiler. A SAS macro comment can be embedded in DS2 programs that are submitted in the DS2 procedure. The macro facility strips SAS macro comments from the program code before the code is passed to the DS2 procedure for further processing. A SAS macro comment used in a DS2 program that is executed outside of the SAS programming runtime environment results in a syntax error and halts compilation.

You can use /.../ and *... in DS2 code for comments.

This example comment provides comments regarding a Test Library using /*...:

```
/*-------------------------------------------------------------
 *
 *                SAS  TEST  LIBRARY
 *
 *      NAME: ds2mod.sas
 *   SUPPORT: saswss
 *     TITLE: MOD function
 *      KEYS: mod function
 *   SYSTEMS: all
```

```
*  COMMENTS: This test is self-validating. A message is printed

*            in the log if an incorrect value is obtained.

-----------------------------------------------------------/
```

This example comment provides details on the eps variable: using *...

```
eps=1.e-12;    *** put eps=;
```

Here is another example that shows the ways that DS2 comments can be used:

```
data _null_;
    dcl double x;
    dcl double y;  /* DS2 comments are preferred in PROC DS2; they
required in other programming environments */
    method init();
        /* multiline comment with
           an embedded semicolon ;
           an embedded single quotation mark '
           an embedded double quotation mark " */
        if (missing(x) or /* multiline comment embedded
                             in a DS2 expression */
            missing(y)) then do;
            put /* comment embedded in a DS2 statement */ 'Hello,
World';
        end;
    end;
enddata;
run;
```

Dictionary

ARRAY Assignment Statement

Assigns either a temporary array or a constant list to a temporary array.

Syntax

array-name:= *array-name*;

array-name:=(*constant-list*);

Required Arguments

array-name
specifies the name of the array.

constant-list
specifies a list that define the array elements.

Details

You can assign either a temporary array or a constant list to a temporary array.

When you assign one array to another array, the data types of the two arrays must be compatible (either the same or convertible). The number of dimensions do not have to be the same for the two arrays, and the total number of elements in each array do not have to be the same.

Example

The following statements are examples of array assignments.

```
ar1:=('sales', 'inv', 'profit');

ar2:=(3*3.14159, 2*'5', 2*(1,2), 99);

ar7:=ar2;
```

"Array Assignment" in *SAS DS2 Programmer's Guide*

Assignment Statement

Evaluates an expression and stores the result in a variable.

Category: Local

Syntax

variable=*expression*;

Required Arguments

variable
names a new or existing variable.

Range *variable* can be a variable name, array reference, or SUBSTR function.

Tip Variables that are created by the Assignment statement are not automatically retained.

expression
is any valid DS2 expression.

Tip *expression* can contain the variable that is used on the left side of the equal sign. When a variable appears on both sides of a statement, the original value on the right side is used to evaluate the expression, and the result is stored in the variable on the left side of the equal sign.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

Details

The Basics

Assignment statements evaluate the expression on the right side of the equal sign and store the result in the variable that is specified on the left side of the equal sign.

The following type conversions take place with the Assignment statement:

- If the variable has a data type and the expression's data type does not match and can be converted, the expression is converted to the variable's data type. If the expression cannot be converted, an error occurs.
- If the variable does not have a data type, then one of the following actions occurs:
  - If the expression's value is not null and has a data type of CHAR, BINARY, DATE, or TIME, then the variable is given the data type of the expression.
  - If the expression's value is not null and of numeric type, then the variable is given a data type of DOUBLE. If the expression's value is null, then the variable is given a data type of DOUBLE.
  - If the expression's type is CHAR or BINARY, then the variable is given the length of the expression's value. If the expression's value cannot be determined at compile time (for example, for VARCHAR strings), the variable is given the default length of 200.
  - If the expression's type is TIME or TIMESTAMP, then the variable is given the expression's precision.
- If an assignment statement is `a = b = 5`, then `b = 5` is an expression. If `b` is a value other than 5, then `b = 5` is evaluated to 0. Therefore, `a` is assigned a value of 0. The first equal sign (=) is an assignment operator and the second equal sign is a logical equality operator.For more information, see "Example 2: Using an Expression with Multiple Equal Signs" on page 1317.

Note: DS2 supports using `eq` as well as the equal sign. For example, `x = y < z < w;` is equivalent to `x = y < z & z < w;`. Another example is that `a = b = c =d;` equates to `a = ((b = c) & (c = d));`.

Examples

Example 1: Different Types of Expressions

These assignment statements use different types of expressions.

- `name='Nagasaki';`
- `FullName='Mr. '||name;`
- `price=price+markup;`
- ```
  declare int i;
  declare double d;
  declare character(200) c;

     i = 5;
     d = 1.2345;
     d = d + i;
     c = 'abc';
     c = d;
     c = '123' || '456';
     i = c;
  ```

Example 2: Using an Expression with Multiple Equal Signs

The result of these assignment statements is **a**=0. The values of b, c, and d are not changed.

```
data;
   dcl double a b c d;

   method init();
      a = b = c = d = 5;
      put _all_;
   end;
enddata;
run;
```

Example 3: Using a Long Literal Enclosed in Brackets

The following example uses nested brackets to assign a long literal string to a VARCHAR variable, s.

```
data _null_;
  method init();
      dcl varchar(100) s;
      s = [===[line 1
               line 2
               line 3 contains a double square bracket [[
```
```

```
                line 4]===];
      put s;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
line 1
line 2
line 3 contains a double square bracket [[
line 4
```

BY Statement

Controls the operation of a MERGE or SET statement in a DS2 program and sets up special grouping variables.

Category: Local

Restriction: The BY statement must immediately follow a MERGE or SET statement. The BY statement is optional when using a SET statement.

Tip: Trailing blanks are always ignored when combining tables with a SET or MERGE statement.

Syntax

BY [DESCENDING] *column*... [DESCENDING] *column*;

Required Argument

column(s)
names each column by which the table is sorted. These columns are referred to as BY variables.

Tip The table can be sorted by more than one column.

Optional Argument

DESCENDING
specifies that the tables are sorted in descending order by the variable that is specified. DESCENDING means largest to smallest numerically, or reverse alphabetical for character variables.

Restriction You cannot use the DESCENDING option with tables that are indexed because indexes are always stored in ascending order.

Details

How DS2 Indicates the Beginning and End of a BY Group

DS2 indicates the beginning and end of a BY group by creating two temporary variables for each BY variable: FIRST.*variable* and LAST.*variable*. The value of these variables is either 0 or 1. DS2 sets the value of FIRST.*variable* to 1 when it reads the first row in a BY group, and sets the value of LAST.*variable* to 1 when it reads the last row in a BY group. These temporary variables are available for DS2 programming but are not added to the result set.

For a complete explanation of how SAS processes grouped data and of how to prepare your data, see "Combining Tables" in *SAS DS2 Programmer's Guide*.

In a Data Program

The BY statement applies only to the SET or MERGE statement that precedes it in a data program, and only one BY statement can accompany each of these statements in a data program. An error occurs if the BY statement appears anywhere else in the data program.

Note: The BY statement recognizes the linguistic collation of data that is sorted by using the SORT procedure with the SORTSEQ=LINGUISTIC option.

Note: Assume you have a table with a column that has a character data type. If you change the column to be a numeric data type on input with a DECLARE statement, the sort order of the resulting column is not numeric. For example, assume the following character column (CHAR) s exists in a table: 9, 10, 500. If you declare s as a numeric column (DOUBLE) when you read the table with a SET and BY statement, the data is generated as output in alphanumeric order, that is, 10, 500, 9. The SET statement orders the rows in alphanumeric order before the string is converted to the numeric data type.

For more information, see "Combining Tables" in *SAS DS2 Programmer's Guide*.

Processing BY Groups

SAS assigns the following values to FIRST.*variable* and LAST.*variable*:

- FIRST.*variable* has a value of 1 under the following conditions:
  - when the current row is the first row that is read from the table.
  - when the value of the current row BY variable differs from the value of that BY variable in the previous row.
  - FIRST.*variable* has a value of 1 for any preceding variable in the BY statement.

  In all other cases, FIRST.*variable* has a value of 0.
- LAST.*variable* has a value of 1 under the following conditions:
  - when the current row is the last row that is read from the table.
  - when the value of the current row BY variable differs from the value of that BY variable in the next row.
  - LAST.*variable* has a value of 1 for any preceding variable in the BY statement.

  In all other cases, LAST.*variable* has a value of 0.

Examples

Example 1: Specifying One or More BY Variables

- Observations are in ascending order of the variable DEPT:

```
by dept;
```

- Observations are in alphabetical (ascending) order by CITY and, within each value of CITY, in ascending order by ZIPCODE:

```
by city zipcode;
```

Example 2: Specifying Sort Order

- Observations are in ascending order of SALESREP and, within each SALESREP value, in descending order of the values of JANSALES:

```
by salesrep descending jansales;
```

- Observations are in descending order of BEDROOMS, and, within each value of BEDROOMS, in descending order of PRICE:

```
by descending bedrooms descending price;
```

Example 3: Using a BY Statement When Combining Tables with a SET Statement

The following example creates two tables and uses a SET statement to combine the tables using the **common** column.

```
data mrg01a(overwrite=yes);
   dcl varchar(10) common animal;
   method init();
      common='a'; animal='Ant'; output;
      common='b'; animal='Bird'; output;
```

```
      common='c'; animal='Cat'; output;
      common='d'; animal='Dog';  output;
      common='e'; animal='Eagle'; output;
      common='f'; animal='Frog';  output;
   end;
enddata;
run;

data mrg01b(overwrite=yes);
   dcl varchar(10) common plant;
   method init();
      common='a'; plant='Apple'; output;
      common='b'; plant='Banana'; output;
      common='c'; plant='Coconut'; output;
      common='d'; plant='Dewberry';  output;
      common='e'; plant='Eggplant'; output;
      common='f'; plant='Fig';  output;
        common='g'; plant='Grapefruit'; output;
   end;
enddata;
run;

/*  set concatenates */
data;
   method run();
      set mrg01a mrg01b; by common;
   end;
 enddata;
run;
```

The following table is generated.

common	animal	plant
a	Ant	
a		Apple
b	Bird	
b		Banana
c	Cat	
c		Coconut
d	Dog	
d		Dewberry
e	Eagle	
e		Eggplant
f	Frog	
f		Fig
g		Grapefruit

Example 4: Using a BY Statement When Combining Tables with a MERGE Statement

The following example creates two tables and uses a MERGE statement to combine the tables using the **common** column.

```
data mrg01a(overwrite=yes);
   dcl char(10) common animal;
   method init();
      common='a'; animal='Ant'; output;
      common='b'; animal='Bird'; output;
      common='c'; animal='Cat'; output;
      common='d'; animal='Dog';  output;
      common='e'; animal='Eagle'; output;
      common='f'; animal='Frog';  output;
   end;
enddata;
run;

data mrg01b(overwrite=yes);
   dcl char(10) common plant;
   method init();
      common='a'; plant='Apple'; output;
      common='b'; plant='Banana'; output;
      common='c'; plant='Coconut'; output;
      common='d'; plant='Dewberry';  output;
      common='e'; plant='Eggplant'; output;
      common='f'; plant='Fig';  output;
      common='g'; plant='Grapefruit'; output;
   end;
```

```
enddata;
run;

/*  match merge */
data;
   method run();
      merge mrg01a mrg01b; by common;
   end;
 enddata;
run;
```

The following table is generated.

common	animal	plant
a	Ant	Apple
b	Bird	Banana
c	Cat	Coconut
d	Dog	Dewberry
e	Eagle	Eggplant
f	Frog	Fig
g		Grapefruit

CONTINUE Statement

Stops processing the current DO loop iteration and resumes with the next iteration.

Category: Local

Syntax

CONTINUE;

Without Arguments

The CONTINUE statement has no arguments. It resumes processing statements with the next iteration of the DO loop.

Details

The CONTINUE statement can appear only in the statement list of an iterative DO loop (for example, DO *i*=, DO WHILE, or DO UNTIL).

Comparisons

- The CONTINUE statement stops the processing of the current iteration of a DO statement and resumes program execution with the next iteration of the current DO statement.
- The LEAVE statement stops the processing of the current DO statement and resumes program execution outside of the current DO statement.

Example

This example illustrates the use of the CONTINUE statement. The DO loop iterates and prints the incremented value of `ctr`. When `ctr` is equal to 3, the CONTINUE statement causes execution to jump to the next iteration of the DO loop, and prevents `ctr` from printing.

```
data _null_;
   dcl int ctr;
   method init();
      do ctr = 1 to 5;
         if ctr = 3 then continue;
         put ctr;
      end;
   end;
enddata;
```

The following lines are written to the SAS log.

```
1
2
4
5
```

- “LEAVE Statement” on page 1382

DATA Statement

Begins a DS2 program and provides names for any output tables.

Category: Block

Alias: TABLE

Syntax

DATA [<table-expression>] [... <table-expression>] ;

... *program-body* ...

[ENDDATA ;]

<table-expression>::=

table (*table-options*)

| **_ROWSET_** (*table-options*)

| **_NULL_**

Without Arguments

If you do not specify any table names with the DATA statement, then the DS2 program returns table rows to the client application and no tables are created.

Required Arguments

table

specifies the name of the table. *table* can be one of these forms.

- *catalog.schema.table-name*
- *schema.table-name*
- *catalog.table-name*
- *table-name*
- *caslib.table-name*

catalog is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

table-name is the name of the table.

caslib.table-name is the name of the table on the CAS server.

Notes If the table name has a dot in it and you are accessing a CAS table, you must enclose the table name in double quotation marks. Here is an example:

```
data mycaslib "tdlibref.foo";
```

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in `data mytable;`, the table name is stored as "MYTABLE" and in `data "MyTable";`, the table name is stores as "MyTable". This is important if table and schema names in your data source are case-sensitive.

CAUTION **Using the PRESERVE_TAB_NAMES=no option on your LIBNAME statement can cause unexpected results.**

ROWSET
specifies that the DATA statement should not create a table, but it should instead return table rows to the client application.

NULL
specifies that the DATA statement should not create a table or return rows to the client application.

table-options
specifies optional arguments that the DS2 program applies when it writes rows to the output table. For more information about table options, see "DS2 Table Options" on page 1471.

Tip _NULL_ can be useful in debugging programs when using PUT statements.

Details

A DS2 program begins with the DATA statement and ends with the ENDDATA statement.

A DS2 program processes input data and produces output data. A DS2 program can run in two different ways: as a program and as a thread. When a DS2 program runs as a program, here are the results:

- Input data can include both rows from database tables and rows from DS2 program threads.
- Output data can be either database tables or rows that are returned to the client application.

When a DS2 program runs as a thread, here are the results:

- Input data can include only rows from database tables, not other threads.
- Output data includes the rows that are returned to the DS2 program that started the thread.

If you specify no table names in the DATA statement, or you specify the keyword _ROWSET_ , then the DS2 program returns table rows to the client application and no tables are created. If you specify no table names in the DATA statement, at least one global variable is required.

No rows are ever written to the _NULL_ table name. Therefore, if_NULL_ is the only table name present in the DATA statement, the DS2 program does not return any rows.

If any other table names are present, then the program creates a table for each *table*, and table rows are written to those tables. For more information, see the "OUTPUT Statement" on page 1400.

A warning is issued for tables with delimited column names that are submitted to data sources that are not case sensitive. Data sources that are not case-sensitive remove the quotation marks and treat the column name as not delimited.

Note: The MongoDB data source has special requirements for creating tables. Depending on your data, you might want to create these tables: a root table, a parent table, and a child table. You can create only root tables with DS2. To create parent and child tables, you must use FedSQL. See the information about MongoDB in *SAS/ACCESS for Relational Databases: Reference*.

Comparisons

For a comparison between packages, DS2 programs, and threads, see "Block Statements" on page 1309.

Examples

Example 1: Creating an Output Table

Use the DATA statement to create one or more output tables. You can use table options to customize the output table. The following DS2 program creates two output tables, EXAMPLE1 and EXAMPLE2 . It uses the table option DROP to prevent the column IDNumber from being written to the EXAMPLE2 table.

```
data example1 example2 (drop=(IDnumber));
```

```
   set sample;
   . . .more statements. . .
enddata;
```

Example 2: When Not Creating a Table

Usually, the DATA statement specifies at least one table name to create an output table. Using the keyword _NULL_ as the table name causes the DS2 program to execute without writing rows to a table. This example writes to the log the value of NAME and ID for each row. An output table is not created.

```
data _null_;
   set sample;
   put Name ID;
enddata;
```

DECLARE Statement

Declares one or more DS2 variables or temporary arrays.

Categories: Global
Local

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

Syntax

DECLARE [PRIVATE] { <data-type> <variable-list> [<having-clause>] } ;

< data-type >::=

<exact-numeric-type> | <approximate-numeric-type> | <binary-string-type> | <string-type>
| <date-type>

<exact-numeric-type> ::=

{**INT** | **BIGINT** | **SMALLINT** | **TINYINT**
| **DECIMAL** [(*precision* [,*scale*])] | **NUMERIC** [(*precision* [,*scale*])] }

<approximate-numeric-type> ::=

{ **DOUBLE** | **DOUBLE PRECISION** | **FLOAT** | **REAL** }

<binary-string-type>::=

BINARY(*length*) | **VARBINARY**(*length*)

<string-type>::=

NCHAR [(*character-length*)]

| **NVARCHAR** [(*character-length*)]

| **CHAR** [(*character-length*)] [CHARACTER SET *character-set-identifier*]

| **VARCHAR** [(*character-length*)] [CHARACTER SET *character-set-identifier*]

<date-type>::=

{ **TIME** | **TIMESTAMP** } [(*precision*)] | **DATE**

<variable-list>::=

{ *variable* [...*variable*] }

| { *variable* <array-declaration> [*variable*...<array-declaration>] }

<array-declaration>::=

\[<array-bound> [, ...< array-bound>] \] | \[* \]

<array-bound>::=

{ [*dim-lower*:] *dim-upper*} | { [*dim-lower*:] {DIM (*a*[,*n*]) }

<having-clause>::=

HAVING <having-option> [... <having-option>]

<having-option>::=

LABEL '*string*' | n'*string*'

| **FORMAT** *format*

| **INFORMAT** *format*

Required Arguments

INT

specifies an integer variable or array.

Alias INTEGER

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

BIGINT

specifies an integer variable or array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

SMALLINT

specifies an integer variable or array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

TINYINT
specifies an integer variable or array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DECIMAL [(*precision* [, *scale*])] | NUMERIC [(*precision* [, *scale*])]
specifies an exact numeric variable or array.

precision
specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

Note Not all data sources can support a precision of 52 digits.

scale
specifies the maximum number of decimal digits that can be stored to the right of the decimal point

Range 0–*precision*

Note *scale* is less than or equal to *precision*.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DOUBLE | DOUBLE PRECISION | FLOAT | REAL
specifies a floating-point variable or array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

BINARY (*length*)
specifies a binary variable or array.

Requirement If you specify BINARY, you must also specify the *length* of the variable or array in bytes.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

VARBINARY (*length*)
specifies a varying-length binary variable or array.

Alias BINARY VARYING

Requirement If you specify VARBINARY, you must also specify the *length* of the binary variable or array in bytes.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

NCHAR
specifies a character variable or array.

Aliases NATIONAL CHARACTER

NATIONAL CHAR

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

NVARCHAR
specifies a character variable or array.

Aliases NATIONAL CHARACTER VARYING,

NATIONAL CHAR VARYING

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

CHAR
specifies a character variable or array.

Alias CHARACTER

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

VARCHAR
specifies a character variable or array.

Alias CHARACTER VARYING

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

character-length
specifies the maximum number of characters that the string can hold for NCHAR, NVARCHAR, CHAR, and VARCHAR data types.

Default 8

Tip The number of bytes that character variables declared using CHAR use for storage depends on the session encoding. Those declared using any of the NCHAR variants have wider storage and can be used to represent character sets for which single-byte character storage is insufficient (for example, Unicode). If a session encoding requires multiple bytes per character (for example, UTF-8), then CHAR and NCHAR are identical types and both use NCHAR.

CHARACTER SET *character-set-identifier*
specifies character set encoding information for CHAR and VARCHAR data types.

Default Default encoding depends on your operating system and locale.

Tip You can use a character string literal or a simple string for character set names. For example, you can specify `"ibm-866"` or `'ibm-866'`.

See For a complete list of character set encoding values, see "Encoding Values in SAS Language Elements" in the *SAS National Language Support (NLS): Reference Guide*.

TIME
specifies a time variable or array.

TIMESTAMP
specifies both a date and time variable or array.

precision
specifies the precision for a TIME or TIMESTAMP data type.

Default 6

Note If you are working with TIME and TIMESTAMP values in a data source other than SAS and you do not specify a precision, the default precision will always be the DS2 default precision of 6.

DATE
specifies a date variable or array.

variable
specifies the scalar variable or array name. You can specify one or more variables or arrays. However, *variable* can only be of the type specified in *data-type*. You can mix scalar and array variables of the same type.

dim-lower* and *dim-upper
specifies a positive or negative integer that defines the number and size of the array boundary for a fixed temporary array.

Tip If the lower bound of a dimension is not specified, then the lower bound defaults to 1.

See "Temporary Array Variable Declaration" on page 1334

\[* \]
specifies to create a temporary array that has dynamic bounds.

See "Dynamic Temporary Array Variable Declaration" on page 1335

DIM(*a*[, *n*])
specifies that the size of the upper bounds of the array is determined by the number of elements in a dimension of a previously declared array by using a DIM function call.

a
specifies the name of a previously declared array.

n
specifies the dimension, in a multidimensional array, for which you want to know the number of elements.

Tip If no *n* value is specified, the DIM function returns the number of elements in the first dimension of the array.

Restriction The DIM function is the only function that you can use to specify an upper array bounds. The DIM function cannot be used to specify the lower bound of a dimension.

See "DIM Function" on page 523

LABEL '*string*' | n'*string*'
assigns a descriptive label to the variable or array. The label can be a CHAR literal (*string*) or NCHAR literal (n*string*).

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

FORMAT *format*
Associates any valid DS2 format with the variable or array.

See "DS2 Formats" on page 61

INFORMAT *informat*
Associates any valid SAS informat with the variable or array.

See Chapter 8, "DS2 Informats," on page 1299

Optional Argument

PRIVATE
specifies variables that can be accessed only from within the package.

See "Attributes and Methods" in *SAS DS2 Programmer's Guide*

Details

Overview of the DECLARE Statement

The DECLARE statement can be used to specify scalar variables and temporary arrays. You can specify temporary arrays that have fixed or dynamic bounds.

More than one variable and array type can be specified in a DECLARE statement. For example, the following DECLARE statement specifies two scalar variables named **x** and **y**, and three temporary arrays named **a**, **b**, and **d**. Arrays **a** and **b** are standard arrays; they specify fixed bounds. Array **d** is a temporary array that has dynamic bounds; it specifies an asterisk as the array bounds.

```
declare double a[10] x y b[20] d[*];
```

A DECLARE statement associates a data type with each variable in a variable list or an array. In the previous example, **x**, **y**, **a**, **b**, and **d** all have a data type of DOUBLE.

The DECLARE statement can declare scalar variables and temporary arrays that are local to a method or global to a program block. All variable declarations can include a HAVING clause.

In DS2, the DECLARE statement is also used for package and thread declarations. For more information about package and thread declaration, see the "DECLARE PACKAGE Statement" on page 1338 and the "DECLARE THREAD Statement" on page 1350.

By default, you receive a warning for any variable that is not declared. If you use a variable without declaring it, DS2 assigns the variable a data type (implicit declaration). The data type for an undeclared variable on the left side of an assignment statement is determined by the data type of the value on the right side of the assignment statement. However, you can use the DS2SCOND system option or the SCOND option on the DS2 procedure to control how DS2 handles an

undeclared variable. You can use these options to require the declaration of all table columns and variables. If you specify DS2SCOND=ERROR or SCOND=ERROR, you must use a DECLARE statement for each column or variable. Declaration by assignment does not occur. For more information, see the "DS2SCOND= System Option" on page 1468, "DS2 Procedure" in *Base SAS Procedures Guide* , and "Variable Declaration" in *SAS DS2 Programmer's Guide*.

Note: Types must be an exact match between a data program and a thread program. For the DECIMAL data type, both the precision and scale must match. For character strings, the column size, the character set, and whether the string is of varying length or fixed length, must all match.

Scalar Variable Declarations

Scalar declarations can be used for numeric, character, date, or time data types. You can specify the maximum number of characters a string can contain. Here is an example.

```
declare char(200) s;
```

DS2 imposes no limit on this number, but, in practice, there might be some restriction due to machine limitation. The default length or precision for a particular data type depends on the data source.

For fixed-length character variables, the maximum length is used as the initial (and only) allocation for the string memory. For varying character strings, memory is allocated on an as-needed basis up to the maximum length. There might be an execution-time advantage to using varying character variables because they do not require blank-padding after an operation as fixed-length character variables do.

The number of bytes that character variables declared using CHAR use for storage depends on the session encoding. Those declared using any of the NCHAR variants have wider storage and can be used to represent character sets for which single-byte character storage is insufficient (for example, Unicode). If a session encoding requires multiple bytes per character (for example, UTF-8), then CHAR and NCHAR are identical types and both use NCHAR.

An error occurs if a variable is declared more than once in the same scope, and the declarations are not identical.

If you use a variable without declaring it, it receives the type of the value assigned to it. If no value is assigned, DS2 assigns the variable as type DOUBLE and assigns the value as a missing or null value.

Temporary Array Variable Declaration

A temporary array is temporary in that the elements of the array are not located in the PDV and therefore do not appear in the result table. Temporary arrays also exist only for the duration of the DS2 program.

Standard Temporary Variable Declaration

Standard temporary array declarations are similar to scalar declarations. However, in addition to the data type and name, you also specify the number and size of the

array bounds. Array bounds are given as a signed integer pair, [*l*:*h*], where *l* represents the lowest index for the given bound and *h* represents the highest index for the given bound. An error is returned if *h*<*l*. If you specify an array bound with only one integer, then that integer is interpreted as the highest index. The default lowest index is 1.

This example declares a temporary array *a* of type DOUBLE and five elements are indexed from 1 to 5.

```
declare double a[5];
```

Multiple bounds (or dimensions) for a temporary array are specified using comma separators. This example declares a two-dimensional character array *b* with 5 elements in the first dimension and 10 elements in the second dimension for a total of 50 elements in the array.

```
declare char b[5,10];
```

This example declares a temporary array *c* with two elements. The array is indexed with a lower bound of 0 and an upper bound of 1.

```
declare int c[0:1];
```

Dynamic Temporary Array Variable Declaration

A dynamic temporary array is a temporary array that is defined with dynamic bounds. Standard temporary array bounds are static, or fixed, at execution time. The number of elements in an array with standard bounds is also fixed at execution time. Dynamic bounds can be changed at execution time, allowing the number of elements in an array with dynamic bounds to expand or contract dynamically as the DS2 program executes.

A dynamic temporary array is created by declaring an asterisk as the array bounds. This example declares a dynamic temporary array **d** of type DOUBLE:

```
declare double d[*];
```

The asterisk defines an array with a single dimension, a lower bound of 1, and an initial upper bound of 0, resulting in a one-dimensional array that is initialized to contain 0 elements. The array's upper bound is set and can be modified at execution time by using the RESIZEARRAY statement. The number of dimensions and lower bound of a dynamic temporary array cannot be changed. A dynamic temporary array is always a one-dimensional array that has a lower bound of 1.

For information about how to specify elements for a dynamic temporary array, see "RESIZEARRAY Statement" on page 1420.

For more information about DS2 arrays, see "DS2 Arrays" in *SAS DS2 Programmer's Guide* and "Temporary Arrays" in *SAS DS2 Programmer's Guide*.

HAVING Clause

You can associate label, format, and informat attributes with one or more scalar variables or an array. The HAVING clause functions the same as the FORMAT, INFORMAT, and LABEL statements in DATA step. However, in DS2, the attributes must be specified in the declaration statement of the variable or array.

For more information about how DS2 handles formats and informats, see "Using Formats in DS2" on page 64 and "How Informats Are Used in DS2" on page 1300.

For more information about arrays and the HAVING clause, see "Declaring Arrays with a HAVING Clause" in *SAS DS2 Programmer's Guide*.

Note: If variables are declared with a HAVING clause in a thread program and the variables are redeclared in a data program with a HAVING clause, the HAVING clause in the data program is used instead of the HAVING clause in the thread program. If there is no HAVING clause in the DECLARE statement in the data program, the HAVING clause in the thread program is not used.

Examples

Example 1: Declaring Variables

The following examples illustrate the DECLARE statement.

- `declare bigint b2 b3;`
- `declare double d;`
- `declare char(200) c1 c2;`
- `declare varchar vc;`
- `declare nchar(100) wc;`
- `declare time(4) tm;`
- `declare date dt;`
- `declare varbinary(10) b;`
- `dcl double x having label 'Amount' format ieee8.2;`
- `dcl char(10) y having label 'varchar' format $quote.;`
- `dcl private double x;`

Example 2: Declaring Standard Temporary Arrays

The following examples illustrate the DECLARE statement for temporary arrays.

- `declare double darr[-5:4];`
- `declare char carr[1:2, 0:3];`
- `declare int iarr[10] having format octal7.;`

Example 3: Standard Temporary Array Dimensions

The following table contains examples of statements that specify standard temporary arrays and the dimensions of those arrays.

Statement	Number of Dimensions	Range of Each Dimension	Number of Elements
`declare double a[100];`	1	1:100	100
`declare double a[10, 20, 30];`	3	1:10 1:20 1:30	10x20x30 = 6000
`declare double a[5:10];`	1	5:10	6
`declare double a[-3:3, 5, 7:9, 10];`	4	-3:3 1:5 7:9 1:10	7x5x3x10 = 1050
`declare double a[DIM(u)];`	1	1:DIM(u)	DIM(u)
`declare double a[DIM(u,1), 0:DIM(u,2)];`	2	1:DIM(u,1) 0:DIM(u,2)	DIM(u,1)x(DIM(u,2)+1)

Example 4: Declaring Temporary Arrays with Dynamic Bounds

The following examples illustrate the DECLARE statement for temporary arrays that are dynamically bound.

- `declare bigint bi[*];`
- `declare binary(4) b[*] having format $hex.;`
- `declare char(10) c1[*];`
- `declare date dt[*];`
- `declare decimal(10,0) dc[*];`
- `declare double d[*];`
- `declare int i[*];`
- `declare nchar(10) nc[*];`
- `declare nvarchar(10) nvc[*];`
- `declare real r[*];`
- `declare smallint si[*];`
- `declare time tm[*];`
- `declare timestamp ts[*];`
- `declare tinyint ti[*];`
- `declare varbinary(4) vb[*] having format $hex.;`
- `declare varchar(10) vc[*];`

DECLARE PACKAGE Statement

Creates a package variable and optionally creates a package instance.

Valid in: All program blocks

Category: Global and Local

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

See: Information for DECLARE PACKAGE statement that is specific to the predefined DS2 packages is documented in the reference section for each package.

Syntax

DECLARE [PRIVATE] **PACKAGE** *package* [(*table-options*)]
<package-variable> [... <package-variable>];

<package-variable::=

{ *scalar-package-variable* [(*constructor-arguments*)] }

| { *array-package-variable*\[array-bounds \] }

| { *array-package-variable*\[array-bounds \] := \[(*constructor-arguments-1*), ... (*constructor-arguments-N*) \] }

<array-bounds>::=

{ \[<array-bound> [, ...<array-bound> \]]}
| { \[* \] }

<array-bound>::=

{ [*dim-lower*:] *dim-upper* }

{ *dim-lower* := *n* }

{ *dim-upper*: *n* } | { DIM (*array-name*[, *n*]) }

Required Arguments

package
specifies the package name. *package* can be one of these forms.

- *catalog.schema.package*
- *schema.package*
- *catalog.package*
- *package*

catalog
is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema
is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

package
is the name of the package.

Requirements The package name must match the name of a package that is created in a PACKAGE statement or must be a predefined DS2 package, or an error will occur.

Package naming conventions are based on the data source. For more information, see the documentation for your data source.

See "PACKAGE Statement" on page 1406

package-variable
specifies whether to create a scalar package variable or an array package variable. You can specify to create multiple package variables with the DECLARE PACKAGE statement.

Optional Arguments

PRIVATE
specifies that the package variables can be accessed only from within the package.

See "Attributes and Methods" in *SAS DS2 Programmer's Guide*

scalar-package-variable
specifies a name that can reference an instance of the package.

array-package-variable\[*array-bounds* \]
specifies a name that can reference multiple instances of the package.

Note An array package variable is a temporary array; therefore, it can have fixed or dynamic bounds. For more information, see "Temporary Arrays" in *SAS DS2 Programmer's Guide*.

dim-lower* and *dim-upper
specifies a positive or negative integer that defines the number and size of the array boundary for a fixed array package variable.

Note If the lower bound of a dimension is not specified, then the lower bound defaults to 1.

See "Temporary Array Variable Declaration"

DIM(*array-name*[, n])
specifies that the size of the upper bound of the array package variable is determined by the number of elements in a dimension of a previously declared array package variable by using a DIM function call.

array-name specifies the name of a previously declared array package variable.

n specifies the dimension in a multidimensional array for which you want to know the number of elements.

Restriction The DIM function is the only function that you can use to specify an upper array bounds. The DIM function cannot be used to specify the lower bound of a dimension.

Tip If no *n* value is specified, the DIM function returns the number of elements in the first dimension of the array.

See DIM Function

\[* \]
specifies to create an array package variable that has dynamic bounds.

See "Dynamic Temporary Array Variable Declaration"

table-options
specifies optional arguments that the DS2 program applies when it creates a package. For more information about table options, see "DS2 Table Options" on page 1471.

constructor-arguments
specifies any constructor arguments that are passed to the constructor of the package instance.

Scalar package variables: A package instance is created and assigned by specifying a set of parenthesis after the package variable name. The parenthesis can contain an empty parameter list or a comma-separated list of values.

```
s()
s('gvar1',gvar2)
```

Array package variables: Constructor arguments must be preceded by an array assignment symbol (:=) and must be contained within square brackets. A separate constructor argument must be specified for each element of the array. Valid constructor arguments are a set of values within parentheses, a set of parentheses without values, or a blank space. The constructor argument for each element must be separated by a comma.

```
arr1[3] := [(), ,('var1',gvar2)];
```

The initialization block can contain fewer or more constructors than the array has elements. If the initialization block contains fewer constructors than the array has elements, uninitialized elements remain NULL references. If the initialization block contains more constructors than elements, the excess constructors are ignored. Package instances that are indicated by a blank space are created as NULL references.

The values in *constructor-arguments* must be valid arguments for one of the constructor methods of the package type of the variable.

Restriction There is currently no way to initialize multiple elements of an array or the entire array with the same constructor parameters.

Note No logs are generated indicating the difference between declared array size and the initialization block array size.

Details

Before you can use a variable or method from a package in another program, you must declare a package variable and construct an instance of the package. The DECLARE PACKAGE statement supports creation of scalar package variables or array package variables. A scalar package variable references a single instance of the specified package. An array package variable is a data structure for grouping multiple package instances. Array package variables have the following characteristics:

- Each element of the array can reference an instance of the package.
- Two or more elements of the array can reference the same package instance.
- An array package variable enables multiple package instances to be referenced using a single variable.

If constructor arguments are provided with the package variable declaration, a package instance is constructed and the package variable or element of the array package variable is set to reference the constructed package instance by the DECLARE PACKAGE statement.

As an alternative to specifying constructor arguments, a package instance can be constructed and assigned to the scalar package variable or element of an array package variable after declaration by using the _NEW_operator.

A scalar package variable or an element of an array package variable can also be populated by copying the reference to an existing package instance from another scalar variable or another element of an array variable using an assignment

statement. Such assignments result in multiple scalar variables or array elements referencing the same package instance.

An array package variable is like any other DS2 temporary array variable. An element of an array package variable can be specified anywhere that an element of a temporary array can be specified. For more information, see "DS2 Arrays" in *SAS DS2 Programmer's Guide*.

The following examples compare how a scalar package variable and an array package variable are declared and can be instantiated. The examples all refer to this package:

```
package dog /inline;
   dcl varchar(100) name;
   dcl varchar(100) breed;
   method dog(varchar(100) name, varchar(100) breed);
   this.name = name;
   this.breed = breed;
   method dog();
  end;
end;
endpackage;
```

Here is an example of a DECLARE PACKAGE statement that declares a scalar package variable and constructs a package instance:

```
declare package dog d('Benji', 'Mixed Breed');
```

The above statement is equivalent to the following two statements:

```
declare package dog d;  1
 d = _new_ dog('Benji', 'Mixed Breed');       2
```

1 Creates a scalar package variable named D for package DOG that is a null package reference.

2 Constructs a package DOG instance and sets scalar package variable D to reference the constructed package instance.

Here is an example of how an array package variable is declared and package instances can be constructed using the DECLARE PACKAGE statement:

```
dcl package dog dogs[4] := \[('Lassie','Collie'), ('Benji, 'Mixed
Breed'), ('Beethoven', 'St. Bernard'), ('Toto', 'Cairn Terrier')\];
```

Constructor parameters that initialize and assign values for all four elements of array package variable DOGS are defined.

Here is an example of how an array package variable is declared using the DECLARE PACKAGE statement and package instances are constructed as a separate step.

```
dcl package dog dogs[4];                          1
dogs[1]= _new_ dog('Lassie','Collie');            2
dogs[2]= dogs[1];                                 3
dogs[4]= _new_ dog('Toto', 'Cairn Terrier');      4
```

1 Creates an array package variable named DOGS that is a fixed array consisting of 4 array elements. The DECLARE PACKAGE statement initializes the array elements as null references.

2 Constructs an instance of package DOG that defines the values 'Lassie' and 'Collie' for the NAME and BREED variables of package DOG and sets element 1 of array package variable DOGS to reference the constructed package instance.

3 Both array element 1 and array element 2 reference the same package instance after the assignment statement.

4 The _NEW_ operator is also used to construct a package instance for element 4 of array package variable DOGS.

Here is an example of how the DECLARE PACKAGE statement would be modified to create array package variable DOGS as a dynamic temporary array.

```
dcl package dog dogs[*];
resizearray dog[4];
```

Specifying an asterisk (*) as the array bounds in the DECLARE PACKAGE statement enables the array bounds to be set with the RESIZEARRAY statement.

Multiple package variables (scalar or array) with constructors can be created using a single DECLARE PACKAGE statement.

Note: Package variables are subject to variable scoping rules, but package instances are not subject to variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

Examples

Note: The examples in this section submit the DS2 programs to the SAS Compute Server using the DS2 procedure.

Example 1: Declaring an Array Package Variable

This example creates an array package variable and uses the _NEW_ operator to instantiate the elements of the array.

```
proc ds2;
package dog / inline;                                  /* 1 */
   dcl varchar(100) name;
   dcl varchar(100) breed;

   method dog(varchar(100) name, varchar(100) breed);
    /* Must use THIS.to distinguish global */
    /* variables NAME and BREED from parameters named NAME */
    /* and BREED */
     this.name = name;
     this.breed = breed;
   end;

   method describe() returns varchar(100);
    return 'My name is ' || name ||
           ', and I am a ' || breed || '.';
```

```
   end;
endpackage;

data _null_;
   method init();
   dcl varchar(100) description;
   dcl int i;

   dcl package dog dogs[4];                                  /* 2 */
   dogs[1]= _new_ dog('Lassie','Collie');                    /* 3 */
   dogs[2]= dogs[1];                                         /* 4 */
   dogs[3]= _new_ dog('Beethoven', 'St. Bernard');
   dogs[1]= dogs[3];
   dogs[4]= _new_ dog('Toto', 'Cairn Terrier');

   do i = 1 to dim(dogs);                                    /* 5 */
     if (not null(dogs[i])) then do;
        description = dogs[i].describe();
        put 'dogs[' i ']:' description;
     end;
   end;
 end;
enddata;
run;
quit;
```

1 Package DOG defines two variables: NAME and BREED, and two methods: DOG and DESCRIBE.

2 Array package variable DOGS is declared as a package variable for package DOG. Array package variable DOGS is a fixed array consisting of four array elements. The DECLARE PACKAGE statement initializes the array elements as null references.

3 The _NEW_ operator constructs an instance of package DOG that defines the values 'Lassie' and 'Collie' for the variables of package DOG and sets element 1 of array package variable DOGS to reference the constructed package instance. The _NEW_ operator is also used to construct a package instance for elements 3 and 4 of the array package variable.

4 An assignment statement sets the package instance referenced by element 1 of array package variable DOGS for element 2 of the array package variable. A second assignment statement is used to change the package instance referenced by element 1 to that referenced by element 3 of the array package variable.

5 The DO loop invokes package method DESCRIBE() to print a description of the DOG instance in each element of array package variable DOGS that is not null.

Here is the output from the program:

```
dogs[ 1 ]: My name is Beethoven, and I am a St. Bernard.
dogs[ 2 ]: My name is Lassie, and I am a Collie.
dogs[ 3 ]: My name is Beethoven, and I am a St. Bernard.
dogs[ 4 ]: My name is Toto, and I am a Cairn Terrier.
```

Example 2: Declaring an Array Package Variable with Constructors

This example creates an array package variable and uses constructors within the DECLARE PACKAGE statement to initiate the array's elements.

```
proc ds2;
package dog /inline;
   dcl varchar(100) name;
   dcl varchar(100) breed;
   method dog(varchar(100) name, varchar(100) breed);
   this.name = name;
   this.breed = breed;
   end;

   method describe() returns varchar(100);
    return 'My name is ' || name ||
           ', and I am a ' || breed || '.';
   end;
endpackage;

data _null_;
   method init();
   dcl varchar(100) name breed description;
   dcl int i;

 dcl package dog dogs[4] := [('Lassie','Collie'), ('Benji', 'Mixed
Breed'),
('Beethoven','St. Bernard'), ('Toto','Cairn Terrier')];

   do i = 1 to dim(dogs);
     if (not null(dogs[i])) then do;
        description = dogs[i].describe();
        put 'dogs[' i ']:' description;
     end;
   end;
 end;
enddata;
run;
quit;
```

```
dogs[ 1 ]: My name is Lassie, and I am a Collie.
dogs[ 2 ]: My name is Benji, and I am a Mixed Breed.
dogs[ 3 ]: My name is Beethoven, and I am a St. Bernard.
dogs[ 4 ]: My name is Toto, and I am a Cairn Terrier.
```

Example 3: Interactions between Scalar Package Variables and Array Package Variables

A scalar package variable and an element of an array package variable are interchangeable. An element of an array and a scalar variable can reference the same package instance.

```
proc ds2;
package dog / inline;
```

```
   dcl varchar(100) name;
   dcl varchar(100) breed;
   method dog(varchar(100) name, varchar(100) breed);
     this.name = name;
     this.breed = breed;
   end;
   method describe() returns varchar(100);
     return 'My name is ' || name ||
            ', and I am a ' || breed || '.';
   end;
endpackage;

data _null_;
   method init();
     dcl package dog var;                          /* 1 */
     dcl package dog arr[4];
     var = _new_ dog('Lassie', 'Collie');          /* 2 */
     arr[1] = var;                                 /* 3 */
     put var.name= arr[1].name=;                   /* 4 */

     arr[2] = _new_ dog('Toto', 'Cairn Terrier'); /* 5 */
     var = arr[2];   /* VARIABLE = ARRAY ELEMENT  /* 6 */
     put var.name= arr[1].name= arr[2].name=;      /* 7 */
   end;
enddata;
run;
quit;
```

1 The DECLARE PACKAGE statement declares a scalar package variable named VAR and an array package variable named ARR. ARR is a fixed array with four array elements.

2 The _NEW_operator constructs an instance of package DOG and assigns it to package variable VAR.

3 An assignment statement sets the array element ARR[1] to reference the same package instance as referenced by package variable VAR.

4 The PUT statement uses dot notation to print the value of the NAME attribute of the package instances referenced by package variables VAR and ARR[1]. Both references return the name "Lassie".

5 The _NEW_operator constructs an instance of package DOG and assigns it to array package variable ARR[2].

6 An assignment statement sets the scalar package variable VAR to reference the same package instance as referenced by array element ARR[2].

7 The PUT statement uses dot notation to print the NAME attribute of the package instances referenced by package variables VAR, ARR[1], and ARR[2].

```
var.name=Lassie arr[1].name=Lassie
var.name=Toto arr[1].name=Lassie arr[2].name=Toto
```

Example 4: Declaring Multiple Package Variables in the DECLARE PACKAGE Statement

This example declares multiple package variables of each type in a single DECLARE PACKAGE statement.

```
proc ds2;
  package dog /inline;
     dcl varchar(100) name;
     dcl varchar(100) breed;
     method dog(varchar(100) name, varchar(100) breed);
     this.name = name;
     this.breed = breed;
     end;

     method describe() returns varchar(100);
      return 'My name is ' || name ||
             ', and I am a ' || breed || '.';
     end;
  endpackage;

  data _null_;
     method init();
     dcl varchar(100) name breed description;
     dcl int i;
     dcl int addedone;

     dcl package dog genx[5] := [('Lassie','Collie'), ('Benji', 'Mixed
Breed'), ('Toto','Cairn Terrier'), ('Digby','Old English Sheepdog'),
('Hooch','Dogue de Bordeaux')]
                      cartoon('Balto', 'Wolf Hybrid')
                      millenials[10] := [('Shadow', 'Golden
Retriever'), ('Chance', 'American Bulldog'), ('Beethoven','St.
Bernard'), , ('Buddy', 'Golden Retriever'), ('Copper','Bloodhound')]
                      boomers[5] := [('Old Yeller', 'Black Mouth Cur'),
('Lassie','Collie'), ('Charlie', 'Bearded Collie Mix'), ('Chinook',
'Alaskan Malamute'),('Toto','Cairn Terrier')];

     put 'Famous Dogs of Generation X:';
     do i = 1 to dim(genx);
       if (not null(genx[i])) then do;
          description = genx[i].describe();
          put '  [' i ']:' genx[ i ].name ',' genx[ i ].breed;
       end;
     end;

     put 'Famous Dogs of the Millenials Generation:';
     do i = 1 to dim(millenials);
       if (not null(millenials[i])) then do;
          description = millenials[i].describe();
          put '  [' i ']:' millenials[ i ].name ','
millenials[ i ].breed;
       end;
     end;

     put 'Famous Dogs of the Boomers Generation:';
```

```
      do i = 1 to dim(boomers);
        if (not null(boomers[i])) then do;
           description = boomers[i].describe();
           put '  [' i ']:' boomers[ i ].name ',' boomers[i].breed;
        end;
      end;

      put 'A Famous Dog of Cartoon:';
      put '  ' cartoon.name ',' cartoon.breed;

      put 'Adding Cartoon to Millenials';
      addedone = 0;
      do i = 1 to dim(millenials);
        if ((addedone < 1) AND null(millenials[i])) then do;
           millenials[ i ] = cartoon;
           addedone = 1;
        end;
      end;

      put 'Famous Dogs of the Millenials Generation:';
      do i = 1 to dim(millenials);
        if (not null(millenials[i])) then do;
           description = millenials[i].describe();
           put '  [' i ']:' millenials[ i ].name ','
millenials[ i ].breed;
        end;
      end;

  end;
  enddata;
  run;
  quit;
```

```
Famous Dogs of Generation X:
  [ 1 ]: Lassie , Collie
  [ 2 ]: Benji , Mixed Breed
  [ 3 ]: Toto , Cairn Terrier
  [ 4 ]: Digby , Old English Sheepdog
  [ 5 ]: Hooch , Dogue de Bordeaux
Famous Dogs of the Millenials Generation:

DECLARE THREAD Statement

Creates an instance of a thread.

Category: Local

Syntax

DECLARE THREAD *thread* [(*table-options*)] *instance*(*argument*) [... *instance* (*argument*)];

Required Arguments

thread
specifies the thread name. *thread* can be one of these forms.

- *catalog.schema.thread*
- *schema.thread*
- *catalog.thread*
- *thread*

catalog
is an implementation of the ANSI SQL standard for a SQL catalog. A SQL catalog is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema
is an implementation of the ANSI SQL standard for a SQL schema. A SQL schema is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

thread
is the name of the thread.

Requirements The thread name must match the name of a thread created in a THREAD statement, or an error occurs.

Thread naming conventions are based on the data source. For more information, see the documentation for your data source.

See "Overview of Threaded Processing" in *SAS DS2 Programmer's Guide*

instance
specifies a name that identifies an instance of the thread.

argument
specifies arguments used with *instance*.

Optional Argument

table-options
specifies optional arguments that the DS2 program applies when it creates a thread. For more information about table options, see "DS2 Table Options" on page 1471.

Details

When a thread is declared, the variable representing the thread can be considered an instance of the thread. This means that two different thread variables represent two completely separate copies of a thread.

Thread variables can appear only in global scope, otherwise an error is returned. If the thread named in the DECLARE statement does not exist, an error is returned.

In this example, the thread `work.t` is instantiated and named `thread_name`:

```
declare thread work.t thread_name;
```

Once an instance of a thread has been created, you can use it in a SET FROM statement. For more information, see the "THREAD Statement" on page 1444. For more information about threads, see "Overview of Threaded Processing" in *SAS DS2 Programmer's Guide*.

See Also

- "Threaded Processing" in *SAS DS2 Programmer's Guide*

Statements:

- "SET FROM Statement" on page 1436
- "THREAD Statement" on page 1444

DO Statement

Specifies a group of statements to be executed as a unit.

Category: Local

Syntax

DO [<numeric-data-type>][*index-variable* = <index-variable-clause>]
[<conditional-clause>]
[, ...[<index-variable-clause>] [<conditional-clause>]];

...*statement-list*...

END [*end-label*] ;

< numeric-data-type >::=

<exact-numeric-type> | <approximate-numeric-type>

<exact-numeric-type> ::=

{**INT** | **BIGINT** | **SMALLINT** | **TINYINT**
| **DECIMAL** [(*precision* [,*scale*])] | **NUMERIC** [(*precision* [,*scale*])] }

<approximate-numeric-type> ::=

{ **DOUBLE** | **DOUBLE PRECISION** | **FLOAT** | **REAL** }

<index-variable-clause>::=

start [TO *stop* [BY *increment*]]

<conditional-clause>::=

WHILE (*expression*) | **UNTIL** (*expression*)

Without Arguments

The DO statement without the index variable argument and clauses is the simplest form of DO group processing. The statements between the DO and END statements are called a **DO group**. In a simple DO loop, statements in the DO group are executed one time only. You can nest DO statements within DO groups. A simple DO statement is often used within IF-THEN/ELSE statements to designate a group of statements to be executed depending on whether the IF condition is true or false.

Required Argument

statement-list
specifies any valid DS2 statements.

Optional Arguments

INT | BIGINT | SMALLINT | TINYINT
specifies an integer variable or array.

Alias INTEGER for INT

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DECIMAL[(*precision* [, *scale*])] | NUMERIC[(*precision* [, *scale*])]
specifies an exact numeric variable or array.

precision
specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

Note Not all data sources can support a precision of 52 digits.

scale
specifies the maximum number of decimal digits that can be stored to the right of the decimal point

Range 0–*precision*

Note *scale* is less than or equal to *precision*.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DOUBLE | DOUBLE PRECISION | FLOAT | REAL
specifies a floating-point variable or array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

index-variable
names a variable that is used as an index counter for the loop.

CAUTION
Avoid changing the index variable within the DO group. If you modify the index variable within the iterative DO group, you might cause infinite looping.

Requirement The variable must resolve to a numeric value.

Tips If the variable is not declared as a local variable, it will end up in the table that is being created unless it is explicitly dropped. For more information about local variables, see "Scope of DS2 Identifiers " in *SAS DS2 Programmer's Guide*.

The index variable can be a THIS expression. For more information, see "THIS Expression" on page 2165.

end-label
The END statement closes the DO loop. The optional *end-label* argument specifies an identifier. This label, created by using the Labels statement, must

match the label immediately preceding the DO statement, or an error will occur. For more information, see the "Labeled Statement" on page 1381.

Clauses

< index-variable-clause >
specifies a numeric scalar expression or series of expressions that determines the number of times that the DO group will be executed.

start
specifies the initial value of the index variable. *start* can be any expression that resolves to a numeric value.

When it is used without TO *stop*, the value of *start* can be a series of items expressed in this form:

item-1 <, ...item-n>

The items can be a number or an expression that yields a number. The DO group is executed once for each value in the list. If a WHILE condition is added, it applies only to the item that it immediately follows.

Requirement When it is used with TO *stop*, *start* must be a number or an expression that yields a number.

Notes The DO group is executed first with *index-variable* equal to *start*. The value of *start* is evaluated before the first execution of the loop.

If *index-variable* is an integral type and *start* is floating-point type, the value of *start* is converted to INTEGER type with possible loss of precision.

TO *stop*
specifies the ending value of the index variable. *stop* can be any expression that resolves to a numeric value.

Notes Execution continues based on the value of *increment* until one of the following conditions is met: the value of *index-variable* passes the value of *stop*, until a WHILE or UNTIL clause that is specified in the DO statement is satisfied, or until a statement in the DO group directs execution out of the loop. The value of *stop* is evaluated before the first execution of the loop.

If *index-variable* is an integral type and *stop* is floating-point type, the value of *stop* is converted to INTEGER type with possible loss of precision. Any change to *stop* made within the DO group does not affect the number of iterations.

BY *increment*
specifies a positive or negative value that controls the incrementing or decrementing of *index-variable*. *increment* can be any expression that resolves to a numeric value.

Notes The value of *increment* is evaluated before the execution of the loop. When *increment* is positive, *start* must be the lower bound and *stop* must be the upper bound of the loop. If *increment* is negative, *start* must be the upper bound and *stop* must be the lower bound of the loop. If no increment is specified, the index variable is incremented by 1.

If *index-variable* is an integral type and *increment* is floating-point type, the value of *increment* is converted to INTEGER type with possible loss of precision. Any change to the increment made within the DO group does not affect the number of iterations.

<conditional-clause>
specifies a clause that returns true or false.

WHILE (*expression*)
causes DO group statements to execute repetitively while a condition is true.

Note A WHILE clause is evaluated before each execution of the loop, so that the statements inside the group are executed repetitively while the expression is true. If the expression is false the first time it is evaluated, the DO loop does not iterate even once.

See Appendix 2, "DS2 Expressions," on page 2143

UNTIL (*expression*)
causes DO group statements to execute repetitively until a condition is true.

Note An UNTIL clause is evaluated after each execution of the loop, so that the statements inside the group are executed repetitively until the expression is true. The DO loop always iterates at least once.

See Appendix 2, "DS2 Expressions," on page 2143

Details

The DO statement allows a group of statements to be executed as a unit. If iterative or conditional clauses are specified, this group of statements can be executed multiple times.

DO loop iteration with an integral index variable is performed using INTEGER arithmetic. Otherwise, DO loop iteration is performed using DOUBLE arithmetic. Because the representation of the DOUBLE type is a binary number, the accumulation of an imprecise number can introduce enough error to prevent execution of the DO loop the expected number of times. For example, this loop might not execute the expected number of times.

```
do i = 0.001 to 10 by 0.001;
```

For more information, see "Numeric Precision" in *SAS Programmer's Guide: Essentials*.

A DO statement defines a scoping block so that any variables declared in the DO statement have scope local to the scope of the DO statement.

There are three forms of the DO statement:

- The DO statement without clauses is the simplest form of DO-group processing. In this form, a group of statements is executed as a unit, usually as a part of IF-THEN/ELSE statements.
- The iterative DO statement can execute statements between DO and END statements repetitively, based on the values of an index variable.
- The DO statement can execute statements in a DO loop repetitively while a conditional clause is true, checking the condition before each iteration of the DO loop. The DO UNTIL form evaluates the condition at the bottom of the loop; the DO WHILE form evaluates the condition at the top of the loop.

  The final value of the loop is, at most, the specified TO value. For example, `do i = 1 to 10` executes the loop 10 times. This is different from other languages (for example, C, where the last iteration is less than the TO value).

The CONTINUE statement can be used within the DO group to cause execution to immediately continue with the next iteration of the DO statement.

The LEAVE statement can be used within the DO statement to transfer execution to either the statement immediately following a specified target DO statement or the current DO statement.

You can declare the loop counter within the DO statement. Here is an example.

```
do double i=0 to 10;
```

The scope of the variable declaration is local to the loop iteration.

Note: Only numeric data types are allowed.

Examples

Example 1: DO Statement with No Clauses

```
do;
   dcl int i j;
      i = 2;
      j = i + 5
end;
```

Example 2: DO with an Index Variable Clause

- ```
  do j = 1 to 10 by 2;
     i + j;
  end;
  ```
- ```
  do k = 11 to 0 by -3;
     i + k;
  end;
  ```

```
x = -2;
y = -1;
do k = 11 to 0 by x + y;
   dcl int i;
   if k < 5 then i = k;
   else
   i = k - 1;
end;
```

```
dcl double i;
do i = 0 to 5 by 0.5;
   put i=;
   /* the values output are */
   /* 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5   */
end;
```

Example 3: DO with an Index Variable Clause Containing a Series

```
dcl int i;
do i = 0 to 10 by 3, 6, 7, 8;
      put i=;
      /*  the values output are*/
      /*  0, 3, 6, 9, 6, 7, 8        */
end;
```

Example 4: DO Statement with a WHILE Clause

```
k = 1;
do while(k <= 5);
   k = k + 1;
end;
```

Example 5: DO Statement with Both an Index Variable and a WHILE Clause

```
j = -2;
do k = 1 to 10 by 2 while (j <= 0);
 j = j + 1;
end;
```

Example 6: DO Statement with an UNTIL Clause

```
k = 1;
do until(k > 6);
   k = k + 1;
end;
```

Example 7: DO Statement with Inline Declaration

This example declares the counter i as a DOUBLE.

```
data _null_;
    method init();
       do double i = 1.1 to 3.1;
```

```
         put i=;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
1.1
2.1
3.1
```

Example 8: DO Statement with Inline Declaration Counting Backward

This example declares the counter i as a DOUBLE.

```
data _null_;
   method init();
      do double i = 1 to '-3' by -1;
         put i=;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
1
0
-1
-2
-3
```

Example 9: DO Statement with Inline Declaration and Non-Numeric Argument

Non-numeric values are assigned to the DOUBLE loop index in the following example. As a result, missing values are written to the log.

```
data _null_;
   method init();
      do double i = 'abc', 123, 'def', 'ghi';
         put i=;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
.
123
.
.
```

- “Labeled Statement” on page 1381
- “LEAVE Statement” on page 1382

DROP Statement

Excludes columns from output tables.

Category: Global

Note: This statement cannot be used within a method.

Syntax

DROP *column-list* | *vararray*;

Required Arguments

column-list
specifies the name of one or more columns to omit from the output tables.

Restriction Numbered range lists in the format *col1–coln* and name prefix lists in the format *col:* are not supported.

vararray
specifies the name of a variable array.

See “VARARRAY Statement” on page 1448

Details

The DROP statement applies to all the tables that are created within the same DS2 program and can appear only in the global statements section of a data, thread, or package program. The columns in the DROP statement are available for processing in the DS2 program. If no DROP or KEEP statement appears, all tables that are created in the DS2 program contain all columns. Do not use both DROP and KEEP statements within the same DS2 program.

Comparisons

- The DROP statement applies to all output tables that are named in the DATA statement. To exclude columns from some tables but not from others, use the DROP= table option in the DATA statement.
- The KEEP statement is a parallel statement that specifies a list of columns to write to output tables. Use the KEEP statement instead of the DROP statement if the number of columns to include is significantly smaller than the number to omit.
- The KEEP and DROP statements select columns to include in or exclude from output tables. The subsetting IF statement selects rows.

Example

- These examples show the correct syntax for listing columns with the DROP statement:
  - `drop time shift batchnum;`
  - `drop grade1 grade2 grade3 grade4;`
- In this example, the columns PURCHASE and REPAIR are used in processing but are not written to the output table INVENTRY:

```
data inventry;
   drop purchase repair;
   method run();
      set table-specification;
      totcost=sum(purchase,repair);
   end;
enddata;
```

- In this example, the first three variables in variable array x are dropped from the output.

```
/* drop x1, x2, x3 */
proc ds2;
data mytest;
   vararray double x[10];
   drop x1-x3;
   method init();
     do i = 1 to 10;
       x[i] = i;
     end;
   output;
   end;
enddata;
run;
quit;
```

See Also

Statements:

- “KEEP Statement” on page 1379

Table Options:

- “DROP= Table Option” on page 1495

DROP PACKAGE Statement

Deletes a DS2 package.

Category: Block Control

Restriction: This statement must be used outside of any other programming block. Programming blocks are delimited by the DATA...ENDDATA, THREAD...ENDTHREAD, or PACKAGE...ENDPACKAGE statements.

Syntax

DROP PACKAGE *package* [(*table-options*)];
RUN;

Required Argument

package
specifies the name of the package to be deleted.

Optional Argument

table-options
specifies optional arguments that the DS2 program applies when it deletes a package. For more information about table options, see “DS2 Table Options” on page 1471.

Details

The DROP PACKAGE statement drops, or deletes, the table that contains the code for the specified DS2 package. The table must have been previously created with a PACKAGE statement.

Note: The RUN statement is required after the DROP PACKAGE statement.

Example

These examples show the syntax for dropping a DS2 package:

```
drop package mypkg;
run;
drop package mypkg (pw='n1234');
run;
```

See Also

Statements:

- "PACKAGE Statement" on page 1406

DROP THREAD Statement

Deletes a DS2 thread program.

Category: Block Control

Restriction: This statement must be used outside of any other programming block. Programming blocks are delimited by the DATA...ENDDATA, THREAD...ENDTHREAD, or PACKAGE...ENDPACKAGE statements.

Syntax

DROP THREAD *thread* [(*table-options*)];

Required Argument

thread
specifies the name of the thread to be deleted.

Optional Argument

table-options
specifies optional arguments that the DS2 program applies when it deletes a thread. For more information about table options, see "DS2 Table Options" on page 1471.

Details

The DROP THREAD statement drops, or deletes, the table that contains the code for the specified DS2 thread. The table must have been previously created with a THREAD statement.

Example

These examples show the syntax for dropping a DS2 program thread:

```
drop thread mythread;
drop thread mythread (pw='n1234');
```

See Also

Statements:

- "THREAD Statement" on page 1444

DS2_OPTIONS Statement

Specifies or changes the default behavior of a DS2 program.

Category: Behavior

Requirement: Unless specified otherwise, the DS2_OPTIONS statement must appear immediately before a DATA, PACKAGE, or THREAD statement. The DS2_OPTIONS statements apply only to the next DATA, PACKAGE, or THREAD program block. This allows program blocks in the same DS2 program to have different option values.

Interaction: When a stored THREAD or PACKAGE program block is loaded by another program block and the loaded program block does not explicitly set an option with the DS2_OPTIONS statement, the loaded program block inherits the option setting from the program block that loaded it. For more information, see "Option Inheritance" on page 1369.

Note: Several of the DS2_OPTIONS options can also be set as a DS2 procedure option or as a DS2 CAS action parameter. When an option is specified in the DS2 procedure or CAS action as well as in this statement, the settings in this statement take precedence. However, not all options behave the same way. For more information, see "Option Scope".

Syntax

DS2_OPTIONS *options*;

Required Argument

options

specifies one or more DS2 options. *options* can be one of the following values:

BIGINTPROCESSING=YES | NO

specifies whether to use BIGINT processing.

BIGINTPROCESSING=NO disables BIGINIT processing. When disabled, values are automatically coerced to DOUBLE before they are passed to built-in functions and formats. For large values that exceed 15–16 digits, this can lead to a loss of precision. BIGINTPROCESSING=YES enables BIGINT processing, which eliminates the automatic coercion to DOUBLE and preserves BIGINT values with full precision.

Default NO

Notes BIGINTPROCESSING is new beginning in 2025.12.

All packages, threads, and data blocks in the DS2 program must use the legacy BIGINT behavior or the new BIGINT behavior. If a package or thread deviates from the specified behavior, a warning is issued that there is a mismatch, and the setting that is inherited from the data block is selected.

Example
```
ds2_options bigintprocessing=yes;
data _null_;
   dcl package mypkg1 p();
enddata;
run;
```

Important BIGINTPROCESSING=YES might result in behavioral differences from prior releases if your program relies on the implicit conversion of integer values (BIGINT, INTEGER, SMALLINT, TINYINT) to DOUBLE before they are passed to built-in functions and formats.

BIGINTPROCESSING=NO should be used to maintain compatibility with existing programs or workflows that assume traditional CAS behavior.

DIVBYZERO=ERROR | IGNORE

specifies how DS2 processes a division by zero operation.

ERROR halts row processing and writes an error to the SAS log.

IGNORE writes a missing or null value to the result set. No message is written to the SAS log.

Default ERROR

LOGICALEXPR=STANDARD | OPTIMIZED

specifies how logical AND and OR expressions in the next program block are evaluated.

STANDARD specifies that DS2 can evaluate both operands of a logical AND or OR expression before returning a result.

OPTIMIZED specifies that DS2 optimize evaluation of the operands of logical AND and OR expressions by returning a result based on the first operand when possible.

Default STANDARD

Interaction

Note This option can also be set in the DS2 procedure or DS2 CAS actions.

Tip Bypassing evaluation of the second operand can avoid calculations that would otherwise be invalid.

See "Short-Circuit Evaluation in DS2" on page 2175

MISSING_NOTE

writes a note to the SAS log when an invalid function argument generates a missing value.

Default An error message is written to the SAS log when an invalid function argument generates a missing value.

MODE=ANSI | SAS

specifies how nonexistent values in fixed character columns and DOUBLE columns are processed.

ANSI treats nonexistent values as NULL values.

SAS treats nonexistent values as SAS missing values.

Default SAS

Note This option can also be set in the DS2 procedure or DS2 CAS actions.

See "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*

MSGLIMIT=n | MIN | MAX

specifies the maximum number of error, warning, and note messages that can be written to the SAS log during the execution of the DS2 program.

n is an integer that specifies the number of error, warning, and note messages that are produced during the execution of the DS2 program are written to the log. When the message limit is reached, DS2 writes an error message to the SAS log stating that the limit was reached. The program continues executing to completion; however, subsequent error, warning, and note messages are not written to the SAS log. *n* can be specified in terms of 1 (*n*); 1,024 (*n*K); 1,048,576 (*n*M); or 1,073,741,824 (*n*G).

For example, the value 8 specifies eight messages, and the value 8K specifies 8,192 messages.

MIN specifies that no error, warning, or note messages that are produced during the execution of the DS2 program are written to the log. Specifying MIN is the same as specifying MSGLIMIT=0.

MAX specifies that all error, warning, and note messages that are produced during the execution of the DS2 program are written to the log.

Default 1,024 messages per execution of a program.

Restriction The MSGLIMIT= option is valid only when MSGORDER=TEMPORAL is set. MSGORDER=STANDARD prints a maximum of 1,024 messages per program execution. This number includes program compilation and execution messages.

Notes The MSGLIMIT= option applies to diagnostic messages that are produced during the execution of the DS2 program. The option has no effect on error messages that are produced during DS2 program compilation, messages that are produced by the PUT statement, and messages that are written to the SAS logging facility.

This option can also be set in the DS2 procedure or DS2 CAS actions.

Tip Messages that are suppressed by MSGLIMIT= can be captured by enabling the App.TableServices.DS2.Runtime.Log logger. Enable the logger at level INFO before running your program.

Important The MSGORDER= and MSGLIMIT= options apply to the DS2 program as a whole. Their settings do not vary by program block.

MSGORDER=STANDARD | TEMPORAL

specifies whether DS2 writes error, warning, and note messages to the SAS log as they are produced or after the DS2 program completes.

STANDARD specifies that DS2 writes the messages after the DS2 program completes. PUT statement messages precede the diagnostic messages in the log.

TEMPORAL specifies that DS2 writes the messages as they are produced. PUT statement messages are interspersed with the diagnostic messages in the log.

Default STANDARD

Restriction The MSGORDER= and MSGLIMIT= options apply to the DS2 program as a whole. Their settings do not vary by program block.

Note This option can also be set in the DS2 procedure or DS2 CAS actions.

Tip Temporal message ordering can aid DS2 program debugging by reporting PUT statement messages and error, warning, and note messages in the order that they are produced. You can insert PUT statements at strategic points in your DS2 program's logic flow to assist in diagnosing the cause of error conditions that produce error, warning, or note messages.

Important A DS2_OPTIONS statement that specifies the MSGORDER= and MSGLIMIT= options must precede the root programming block for the DS2 program in order for the options to be recognized. The root programming block is the DATA programming block, if the DS2 program contains one. When the DS2 program contains only PACKAGE programming blocks, the last package programming block is considered the root.

REPORTLINE=YES | NO

specifies whether log line numbers for the next program block are reported in DS2 program execution messages. The log line numbers are included in error, warning, and note messages and indicate the location of the DS2 statement that was being executed when the message was generated. Line numbers that are reported for stored packages and threads are the line numbers that are offset from the start of the package or thread block rather than SAS log line numbers.

YES

generates line numbers for DS2 program execution messages.

NO

suppresses generation of the log line numbers.

Default YES

Notes REPORTLINE= controls messages that are generated by DS2 services while executing a statement of a DS2 program. It has no effect on messages that are generated during program pre-processing and post-processing, or by SAS/ACCESS services. REPORTLINE=NO has no effect on line numbers that are reported in DS2 program compilation messages.

This option can also be set in the DS2 procedure or DS2 CAS actions.

SAS

specifies that nonexistent values in fixed character columns and DOUBLE columns are processed as SAS missing values.

Default DS2 processes nonexistent values as SAS missing values.

See "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*

Important The SAS option is superseded by the MODE= option. The SAS option is supported for backward compatibility.

SCOND

specifies the level of messages that is displayed in the SAS log for the DS2 variable declaration strict mode, which requires that every variable must be declared in the DS2 program. For more information about the DS2 variable declaration strict mode, see "Variable Declaration" in *SAS DS2 Programmer's Guide*.

WARNING	writes warning messages to the SAS log.
NONE	no messages are written to the SAS log.
NOTE	writes notes to the SAS log.
ERROR	writes error messages to the SAS log.

Default The default is determined by the DS2SCOND= system option. The default for DS2SCOND= is WARNING. For more information, see "DS2SCOND= System Option" on page 1468.

Note This option can also be set in the DS2 procedure or DS2 CAS actions.

TRACEVARIABLES

enables tracing of variable value changes during DS2 program execution.

Requirement The DS2 App.TableServices.DS2.Runtime.TraceVariables logger must also be configured and set to TRACE or DEBUG. See "App.TableServices.DS2.Runtime.TraceVariables" in *SAS DS2 Programmer's Guide* for a list of the statements and functions for which variable changes are traced.

Interaction This option enables tracing for the program block directly below the DS2_OPTIONS statement. To enable variable tracing of more than one program block, you must specify a DS2_OPTIONS statement before each program block that you want to trace.

Example "Example: Logging Trace Variables" in *SAS DS2 Programmer's Guide*

TREEALGORITHM=ITERATIVE | RECURSIVE

changes the default algorithm that the DS2 compiler uses to build the syntax tree. If you are using the RECURSIVE option and you encounter a stack overflow error, changing the algorithm can sometimes resolve stack overflow errors.

Defaults SAS programming runtime environment: RECURSIVE

CAS: ITERATIVE

Note This option can also be set in the DS2 procedure or DS2 CAS actions.

TYPEWARN

prints a warning to the SAS log when an implicit type conversion occurs.

Details

Option Inheritance

The following log fragment illustrates the inheritance that occurs when a stored THREAD or PACKAGE program block is loaded by another program block and the loaded program block does not explicitly set an option with the DS2_OPTIONS statement. When the stored package Compute is loaded on line 13 by the first DATA program block, the package inherits the IGNORE setting for the DIVBYZERO option. When the stored package Compute is loaded on line 25 by the second DATA program block, the package inherits the ERROR setting for the DIVBYZERO option.

```
1     proc ds2;
2     package compute / overwrite=yes;
3      method div(double x, double y) returns double;
4       return x/y;
5      end;
6     endpackage;
7     run;
7    !   quit;
NOTE: Created package compute in data set work.compute.
NOTE: Execution succeeded. No rows affected.
...
8
9     proc ds2;
10     ds2_options divbyzero=ignore;
11     data _null_;
12      method init();
13       dcl package compute p();
14       dcl double d;
15       d = p.div(10, 0);      /* divide by zero ignored */
16       put d=;
17      end;
18     enddata;
19     run;
19    !   quit;
d=.
NOTE: Execution succeeded. No rows affected.
...
20
21     proc ds2;
22     ds2_options divbyzero=error;
23     data _null_;
24      method init();
25       dcl package compute p();
26       dcl double d;
27       d = p.div(10, 0);      /* divide by zero halts processing */
28       put d=;
29      end;
30     enddata;
31     run;
31    !   quit;
ERROR: Line 3: Float divide by zero
ERROR: General error
```

```
NOTE: PROC DS2 has set option NOEXEC and will continue to prepare statements.

NOTE: The SAS System stopped processing this step because of errors.
```

Option Scope

When an option is specified in the DS2 procedure or CAS action as well as in this statement, the settings in this statement take precedence. The following table summarizes the behavior when a DS2_OPTIONS option is set in this statement and as a DS2 procedure option or DS2 CAS action parameter.

Table 10.1 *Summary of Option Scope*

DS2_OPTIONS Option	Overrides the Procedure Setting for the Specified Program Block[1]	Overrides the Procedure Setting for the Entire DS2 Program[2]
LOGICALEXPR=	*	
MODE=	*	
MSGLIMIT=		*
MSGORDER=		*
REPORTLINE=	*	
SAS	*	
SCOND=	*	
TREEALGORITHM=	*	

1 An option value that a program block inherits from a loading program also takes precedence over the procedure or action setting. The procedure or action value is enforced for any remaining program blocks in the DS2 program.

2 These values must be consistent across all the program blocks of the DS2 program. The procedure or action value is applied only if there is no explicit setting in the DS2_OPTIONS statement of the root program block.

Example: Specifying DS2_OPTIONS Options

Here are some code fragments that specify DS2_OPTIONS options:

```
ds2_options scond=error;
ds2_options divbyzero=ignore;
ds2_options msgorder=temporal msglimit=2K;
ds2_options mode=ansi;
```

ENDDATA Statement

Marks the end of a DATA statement.

Category: Block

Alias: ENDTABLE

Syntax

ENDDATA;

Details

A DS2 program can have multiple package subprograms followed by an optional data program. The following restrictions apply:

- There can be only one data program and the data program must be the last subprogram.
- The ENDPACKAGE, ENDTHREAD, or ENDDATA statements are optional for the last subprogram of the DS2 program. These statements are required for all other subprograms.

See Also

Statements:

- “DATA Statement” on page 1325

ENDPACKAGE Statement

Marks the end of a PACKAGE statement.

Category: Block

Syntax

ENDPACKAGE;

Details

A DS2 program can have multiple subprograms followed by an optional data program. The following restrictions apply:

- There can be only one data program and the data program must be the last subprogram.
- The ENDPACKAGE, ENDTHREAD, or ENDDATA statements are optional for the last subprogram of the DS2 program. These statements are required for all other subprograms.

See Also

Statements:

- "PACKAGE Statement" on page 1406

ENDTHREAD Statement

Marks the end of a THREAD statement.

Category: Block

Syntax

ENDTHREAD;

Details

A DS2 program can have multiple thread subprograms followed by an optional data program. The following restrictions apply:

- There can be only one data program and the data program must be the last subprogram.
- The ENDPACKAGE, ENDTHREAD, or ENDDATA statements are optional for the last subprogram of the DS2 program. These statements are required for all other subprograms.

See Also

Statements:

- “THREAD Statement” on page 1444

FORWARD Statement

Indicates that the method definition follows the method expression.

Category: Global

Syntax

FORWARD *method* [...*method*];

Required Argument

method
specifies the name of the method to be defined.

Details

When a method definition appears after any method expression that refers to it, a FORWARD statement for the method must be declared before the method expression. Otherwise, the DS2 compiler cannot determine whether the method expression refers to a method.

Example

- In this example, the D method is called inside the RUN method. Because the D method is defined after it is called, a FORWARD statement must be specified before the D method is called.

```
forward d;
method run();
   d = d();
   d = d(100);
end;
method d() returns double;
   return 99;
end;
method d(int y) returns int;
   return 100 + y;
```

```
end;
```

- This example creates a user-defined method, SIN, that masks the system function SIN. The user method calls the system function SIN.

```
forward sin;
method run()
   d = sin(3.14159/2);
   put 'd= ' d;
end;
method sin(double x) returns double;
   return system.sin(x);
end;
```

GOTO Statement

Transfers execution immediately to a labeled statement.

Category: Local

Syntax

GOTO *label*;

Required Argument

label
specifies a statement label that identifies the GOTO destination.

Details

The destination label for the GOTO statement must be within the same DS2 method. You must specify the *label* argument or an error occurs. Statement labels are defined by using the Labels statement.

Comparisons

GOTO statements can often be replaced by DO-END and IF-THEN/ELSE programming logic.

Example

In this example, when x = 2, program execution transfers to the DONE label.

```
method run();
   x = 1;
   do;
      if x=2 then goto done;
      put x;
      x+1;
   end;
   done:
   put x;
end;
```

Statements:

- “DO Statement” on page 1352
- “Labeled Statement” on page 1381
- “LEAVE Statement” on page 1382

IF Statement: Subsetting

Continues processing only those rows that meet the condition.

Category: Local

Syntax

IF *expression*;

Required Argument

expression
is any valid expression that evaluates to true or false.

See “DS2 Expressions” in *SAS DS2 Programmer’s Guide*

Details

The expression in a subsetting IF statement is evaluated to produce a result that is either a nonzero value or zero. A nonzero value causes the expression to be true; a result of zero causes the expression to be false.

The subsetting IF statement is equivalent to this IF-THEN statement:

```
if not (expression)
   then return;
```

If *expression* is true, DS2 continues to execute statements in the program.

Note: In logical operations, any expression, such as a subsetting IF statement, a missing value evaluates to False in SAS mode; a null value evaluates to neither true nor false in ANSI mode.

Note: A nonretained variable from the input table is reset to missing or null if it is used before the SET or MERGE statement in the RUN method.

Comparisons

Use the IF-THEN/ELSE statement to process statements when both true and false conditions are present or when more processing is required before values are generated.

See Also

Statements:

- "IF-THEN/ELSE Statement" on page 1376

IF-THEN/ELSE Statement

Executes a statement for rows that meet specific conditions.

Category: Local

Syntax

IF *expression* **THEN** *statement*;
[ELSE *statement* ;]

Required Arguments

expression
is any valid expression that evaluates to true or false and is a required argument.

See "DS2 Expressions" in *SAS DS2 Programmer's Guide*

statement
can be any executable statement or DO group.

Details

The expression in an IF-THEN statement is evaluated to produce a result that is either a nonzero value or zero. A nonzero value causes the expression to be true; a result of zero causes the expression to be false.

Note: In logical operations, including the IF-THEN/ELSE statement, a SAS missing value and a null value evaluate to zero (or false). To check for a null value in an IF-THEN-ELSE statement, you must use the NULL function as shown in this example.

```
method init ();
   x=null;
   if (null(x)) then
      put 'null';
   else
      put 'not null';
end;
```

If the conditions that are specified in the IF clause are met, the IF-THEN statement executes a statement. An optional ELSE statement gives an alternative action if the THEN clause is not executed. The ELSE statement, if used, must immediately follow the IF-THEN statement.

Using IF-THEN statements *without* the ELSE statement causes all IF-THEN statements to be evaluated. If the IF clause is true, the statement after THEN is executed, otherwise the statement after ELSE is executed.

Note: For greater efficiency, construct your IF-THEN/ELSE statement with conditions of decreasing probability.

Note: You can use an IF expression to select between two values based on whether a conditional evaluates to true or false. In addition, IF expressions can be nested to select between many values for a multi-way decision. For more information, see "IF Expression" on page 2150.

Comparisons

- Use a SELECT expression rather than a series of IF-THEN statements when you have a long series of mutually exclusive conditions. A large number of nested IF-THEN/ELSE statements could cause an internal error. By contrast, the SELECT expression is evaluated only once, which could improve performance.
- Use subsetting IF statements, without a THEN clause, to continue processing only those expressions that evaluate to nonzero values when the condition indicates that no more processing is required and no output is to be produced.

Example

These examples illustrate the IF-THEN/ELSE statement.

- ```
  if a = b then
     d = e;
  else
     d = f;
  ```
- ```
  if status='OK' and type=3 then count+1;
  ```
- ```
  if x=0 then
     if y ne 0 then put 'X ZERO, Y NONZERO';
     else put 'X ZERO, Y ZERO';
  else put 'X NONZERO';
  ```
- ```
  if answer=9 then
     do;
        answer=.;
        put 'INVALID ANSWER FOR ' id=;
     end;
  else
     do;
        answer=answer10;
        valid+1;
     end;
  ```
- ```
  xx = if
     if x then y
     else z then b
  else c;
  ```

Statements:

- “IF Statement: Subsetting” on page 1375
  ```

KEEP Statement

Includes columns in output tables.

Category: Global

Note: This statement cannot be used within a method.

Syntax

KEEP *column-list* | *vararray*;

Required Arguments

column-list
specifies the names of one or more columns to write to the output table.

Restriction Numbered range lists in the format *col1–coln* are not supported.

vararray
specifies the name of a variable array.

See "VARARRAY Statement" on page 1448

Details

The KEEP statement specifies that all columns in the column list should be included in the creation of output rows. When the KEEP statement is specified, all columns that are not included in the KEEP statement are dropped from the output rows. When no DROP or KEEP statement appears, all tables that are created in the DS2 program contain all columns. Do not use both DROP and KEEP statements within the same DS2 program.

Comparisons

- The KEEP statement applies to all output tables that are named in the DATA statement. To write different columns to different tables, you must use the KEEP= table option.
- The DROP statement is a parallel statement that specifies columns to omit from the output table.
- The KEEP and DROP statements select columns to include in or exclude from output tables. The subsetting IF statement selects rows.

- Do not confuse the KEEP statement with the RETAIN statement. The RETAIN statement holds a row value in a column from one iteration of the DS2 RUN method to the next iteration. The KEEP statement does not affect the row values, but specifies only which columns to include in any output tables.

Examples

Example 1

This example uses the KEEP statement to include only the columns NAME and AVG in the output table.

```
data;
   keep name avg;
   method run();
      set table-specification;
   end;
enddata;
```

Example 2

In this example, the first three variables in variable array x are kept in the output.

```
/* keep x1, x2, x3 */
proc ds2;
data mytest;
   vararray double x[10];
   keep x1-x3;
   method init();
     do i = 1 to 10;
       x[i] = i;
     end;
     output;
   end;
enddata;
run;
quit;
```

Table Options:

- “KEEP= Table Option” on page 1515

Labeled Statement

Identifies a statement that is referred to by another statement.

Category: Local

Syntax

label: *statement*; [... *statement*];

Required Arguments

label
specifies any identifier, which is followed by a colon (:). You must specify the label argument.

Range 1–255 characters

Restriction If the label contains non-Latin characters, you must enclose it in double quotation marks.

statement
specifies any executable statement, including a null statement (;). You must specify the statement argument.

Details

A label associates an identifier with a given statement so that the statement can be referred to by other statements, such as GOTO and LEAVE. You can have multiple labels for a statement.

Comparisons

The LABEL attribute of the DECLARE statement's HAVING clause assigns a descriptive label to a column. A statement label identifies a statement or group of statements that are referred to in the same DS2 program by another statement, such as GOTO or LEAVE.

Example

```
restock:
```

```
if x > 1 then
   y = 3;
else
   y = 5;
```

- ```
  label1:
     label2:
        do i = 1 to 3;
           j = j * i;
        end;
  ```

See Also

Statements:

- “GOTO Statement” on page 1374
- “LEAVE Statement” on page 1382

LEAVE Statement

Stops processing the current DO loop and transfers execution to either the statement following the current DO statement, or a labeled DO statement that encloses the current DO statement.

Category: Local

Syntax

LEAVE [*identifier*] ;

Without Arguments

The LEAVE statement stops the processing of the current DO statement and resumes processing with the next statement following the current DO statement.

Optional Argument

identifier
label associated with the target DO statement.

Details

You can use the LEAVE statement to exit a DO loop prematurely. You can use the LEAVE statement either on its own or use it based on a condition (for example, in conjunction with an IF statement). If the LEAVE statement is not followed by an
  ```

identifier, then the target is the DO statement immediately enclosing the LEAVE statement. If the LEAVE statement is followed by an identifier, then the target is the DO statement with the label specified by the identifier. The target DO statement must enclose the current DO statement. An error occurs if the identifier specifies a statement other than a DO statement, or a DO statement that does not enclose the current DO statement. An error also occurs if the specified label does not exist.

Comparisons

- The LEAVE statement stops the processing of the current DO statement and resumes program execution outside of the current DO statement.
- The CONTINUE statement stops the processing of the current iteration of a DO statement and resumes program execution with the next iteration of the current DO statement.

Examples

Example 1: LEAVE Statement without an Identifier

This example illustrates the LEAVE statement without an identifier.

```
data _null_;
   dcl int i;
   method init();
      do i = 1 to 10;
         if i > 4 then leave;
         put i;
      end;
   end;
enddata;
```

The following lines are written to the SAS log.

```
1
2
3
4
```

Example 2: LEAVE Statement with an Identifier

This example illustrates the LEAVE statement with an identifier.

```
data _null_;
   dcl int sum i j k ;
   method init();
      lab1: do i = 1 to 5;
         sum + 1;
      lab2: do j = 1 to 3;
         sum + 1;
```

```
            do k = 1 to 3;
               put sum i j k;
               sum + 1;
               if j = 2 then
                  leave lab2;
               if i = 2 then
                  leave lab1;
               if k = 2 then
                  leave ;
               end;
            end;
            end;
   end;
enddata;
```

The following lines are written to the SAS log.

```
2 1 1 1
3 1 1 2
5 1 2 1
8 2 1 1
```

Statements:

- “CONTINUE Statement” on page 1323
- “DO Statement” on page 1352

MERGE Statement

Joins rows from two or more tables into a single row.

Category:	Local
Restriction:	Tables that are in SPD Engine or HDMD format do not support the MERGE statement.
Requirement:	The MERGE statement must be followed by a BY statement.
Note:	The variables that are read using the MERGE statement are set to either a missing or null value.
Tip:	The width of the resulting column is determined by the largest width across all the tables in a single SET statement. Trailing blanks are irrelevant to the MERGE statement.

Syntax

MERGE <table-reference> <table-reference> [... <table-reference>] [/RETAIN];

<table-reference>::=

{ *table* [(*table-options*)] }

Required Argument

table

specifies the name of the table. *table* can be one of these forms.

- *catalog.schema.table-name*
- *schema.table-name*
- *catalog.table-name*
- *table-name*
- *caslib.table-name*

catalog	is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.
schema	is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.
table-name	is the name of the table.
caslib.table-name	is the name of the table on the CAS server.

Notes

If the table name has a dot in it and you are accessing a CAS table, you must enclose the table name in double quotation marks. Here is an example:

```
data mycaslib "tdlibref.foo";
```

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in `data mytable;`, the table name is stored as "MYTABLE" and in `data "MyTable";`, the table name is stored as "MyTable". This is important if table and schema names in your data source are case-sensitive.

CAUTION **Using the PRESERVE_TAB_NAMES=no option in your LIBNAME statement can cause unexpected results.**

Optional Arguments

(table-options)

specifies optional arguments that the DS2 program applies when it writes rows to the output table.

Note For more information about table options, see "DS2 Table Options" on page 1471.

/RETAIN

specifies that the final row of a data set in a particular BY group be used repeatedly until there are no more rows in any of the contributing data sets.

Tip Use this argument to achieve merge behavior like that of a DATA step merge.

Details

The MERGE statement is flexible and has a variety of uses in DS2 programming. This section describes basic uses of MERGE. Other applications include using more than one BY variable, merging more than two tables, and merging a few rows with all rows in another table.

Match-merging combines rows from two or more tables into a single row in a new table according to the values of a common variable. The number of rows in the new table is the sum of the largest number of rows in each BY group in all tables. To perform a match-merge, use a BY statement immediately after the MERGE statement. The variables in the BY statement must be common to all tables. Only one BY statement can accompany each MERGE statement in a data program.

For more information, see "Match-Merging" in *SAS DS2 Programmer's Guide*.

CAUTION

BY variables in a DS2 merge that have a DECIMAL or NUMERIC data type are converted to a DOUBLE data type. If matching DECIMAL columns are not BY variables, the DECIMAL columns remain as a DECIMAL data type.

CAUTION

If there is a type, scale, or precision mismatch between columns with a DECIMAL or NUMERIC data type between tables, the column is converted to a DOUBLE data type.

Note: The order of the data sets in the MERGE statement can affect the matching.

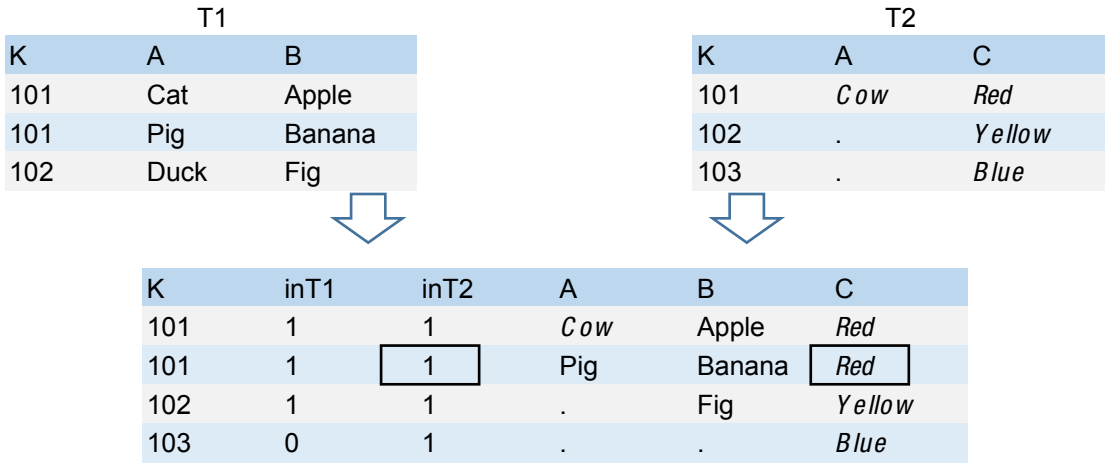
Note the difference in merging behavior between the DATA step and DS2. The MERGE statement does not produce a Cartesian product on a many-to-many match-merge. Instead, it performs a sparse one-to-one merge while there are rows in the BY group in at least one table. In comparison to DATA step merging, the result of the DS2 MERGE statement is a subset of the Cartesian product. By contrast, the result of the DATA step merge is not a subset because it uses a lazy retain strategy to fill in the PDV.

Here is the code.

```
merge T1 (in=inT1) T2 (in=inT2); by K;
```

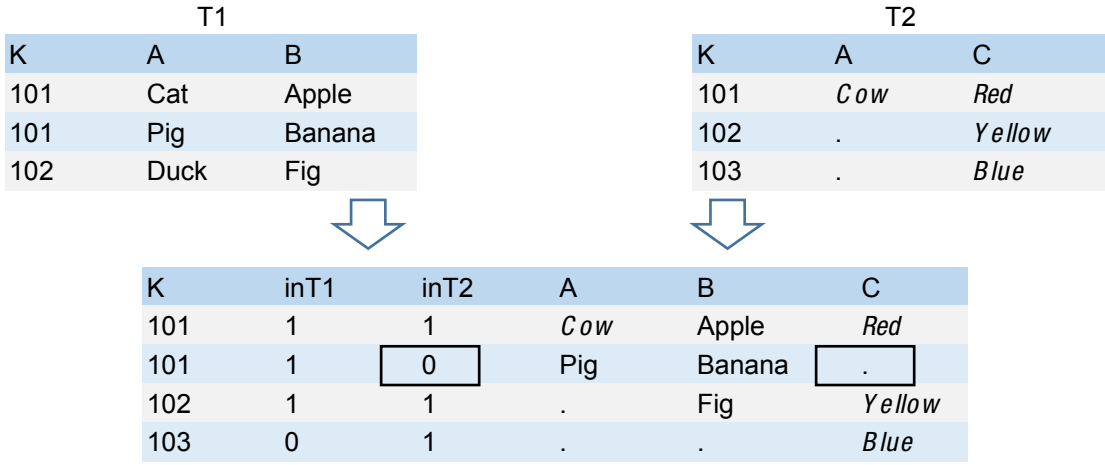
The following example shows the DATA step retain strategy during the merging of the tables T1 and T2 by a common variable K. When match-merging of the second row of table T1 occurs, the value of column C is retained from the previous match of the BY variable. The variable inT2 is set to `1` indicating that table T2 contributed to the final table results.

Figure 10.1 *DATA Step Merge*



In contrast to the DATA step merge, the DS2 merge clears the PDV between BY-group processing. Because the second row in table T1 does not have a corresponding match in table T2, column C remains empty and the variable inT2 is set to `0` indicating that table T2 did not contribute to the final table results.

Figure 10.2 DS2 Merge



You can use the RETAIN argument in the MERGE statement to produce a many-to-many match-merge that is similar to a DATA step merge. To see the same DS2 program shown above produce similar results as the DATA step program, see "Example 2: Merging Tables with Retained Rows" on page 1389.

Match-merging tables that do not contain a one-to-one row mapping between the table rows can produce unexpected results. Within a given BY group, observations in a BY group are not necessarily selected in the order in which they appear in the data set during match-merging.

Note: The MongoDB data source has special requirements for creating tables. Depending on your data, you might want to create these tables: a root table, a parent table, and a child table. You can create only root tables with DS2. To create parent and child tables, you must use FedSQL. See the information about MongoDB in *SAS/ACCESS for Relational Databases: Reference*.

Comparisons

If you specify a SET statement, SAS stops processing before all rows are read from all tables if the number of rows are not equal. In contrast, SAS continues processing all rows in all tables that are named in the MERGE statement.

Examples

Example 1: Merging Two Tables Using One Column

The following example creates two tables and uses a MERGE statement to combine the tables using the `common` column.

```
data mrg01a(overwrite=yes);
   dcl varchar(10) common animal;
   method init();
```

```
      common='a'; animal='Ant'; output;
      common='b'; animal='Bird'; output;
      common='c'; animal='Cat'; output;
      common='d'; animal='Dog';  output;
      common='e'; animal='Eagle'; output;
      common='f'; animal='Frog';  output;
   end;
enddata;
run;

data mrg01b(overwrite=yes);
   dcl varchar(10) common plant;
   method init();
      common='a'; plant='Apple'; output;
      common='b'; plant='Banana'; output;
      common='c'; plant='Coconut'; output;
      common='d'; plant='Dewberry';  output;
      common='e'; plant='Eggplant'; output;
      common='f'; plant='Fig';  output;
      common='g'; plant='Grapefruit'; output;
   end;
enddata;
run;

/*  match merge */
data;
   method run();
      merge mrg01a mrg01b; by common;
   end;
 enddata;
run;
```

The following table is generated.

common	animal	plant
a	Ant	Apple
b	Bird	Banana
c	Cat	Coconut
d	Dog	Dewberry
e	Eagle	Eggplant
f	Frog	Fig
g		Grapefruit

Example 2: Merging Tables with Retained Rows

The following example re-creates the data sets shown in the Details sections and merges them using the RETAIN argument to produce a result that is similar to the Cartesian product that the DATA step produced.

```
/********** create data sets ***********/
proc ds2;
data t1 (overwrite=yes);
   dcl double k;
   dcl char a b;
   method init();
      k=101; a='Cat'; b='Apple'; output;
      k=101; a='Pig'; b='Banana'; output;
      k=102; a='Duck'; b='Fig'; output;
   end;
enddata;
run;
quit;

proc ds2;
data t2 (overwrite=yes);
   dcl double k;
   dcl char a c;
   method init();
      k=101; a='Cow'; c='Red'; output;
      k=102; a='' ; c='Yellow'; output;
      k=103; a='' ; c='Blue';  output;
   end;
enddata;
run;
quit;

/*************Merge with Retain argument **********/
proc ds2;
data ds2merge (overwrite=yes);
   dcl double k;
   dcl char a b c;
   method run();
      merge t1 t2 /retain;
      by k;
   end;
enddata;
run;
quit;

proc print data=ds2merge;
run;
quit;
```

The following table is created. It is identical to the table produced by the DATA step merge code shown in “Details” on page 1386.

Obs	k	a	b	c
1	101	Cow	Apple	Red
2	101	Cow	Banana	Red
3	102		Fig	Yellow
4	103			Blue

- "SET Statement" on page 1430

METHOD Statement

Defines a block of code that can be called and executed multiple times.

Category: Block

Syntax

[PRIVATE] **METHOD** *method* ([[IN_OUT] <parameter> [, ... [IN_OUT]< parameter>]])

[RETURNS *data-type*];

Required Arguments

method

specifies a name for the method. Method names have global scope.

method-body

comprises the variable declarations and executable DS2 code that runs when the method is called. All variables that are declared in the method body are local to the method.

END

marks the end of the method.

Optional Arguments

PRIVATE

specifies a method that can be accessed only from within the package.

See "Attributes and Methods" in *SAS DS2 Programmer's Guide*

IN_OUT

specifies that the argument is to be manipulated by reference, not by value. The IN_OUT parameter manipulates the argument rather than a copy of the argument.

Requirements: The argument that is passed to the IN_OUT parameter must be a modifiable value, such as an identifier, not an expression.

The data type of the argument must be the same data type as the IN_OUT parameter.

Note: If the method declaration specifies a length for an IN_OUT parameter, a warning is issued and the length is ignored. The length of the supplied argument is always used.

Tip: DS2 methods can support thousands of arguments. The number of arguments supported with a DS2 method varies, depending on the data type of the arguments and the system in which the DS2 program is run. A DS2 method that exceeds the number of supported arguments generates a compilation error.

See "Use Caution When Using the IN_OUT Parameter" on page 1396

"Passing Character Values to Methods" on page 1395

parameter

specifies a parameter that is passed to the method. The type can be any valid character, numeric, or date type, or package. Parameters have scope that is local to the method and, by default, parameters are passed by value. A parameter is initialized to be a copy of the value of the argument that is specified for the parameter, unless it is specified with the IN_OUT parameter or is a package or

an array. Package type variables and arrays are always passed by reference, even if the IN_OUT keyword is not specified.

Interaction If the IN_OUT parameter or a package parameter is specified, the value of the argument that is passed into the parameter might have changed when the method returns.

Tip DS2 methods can support thousands of arguments. The number of arguments supported with a DS2 method varies, depending on the data type of the arguments and the system in which the DS2 program is run. A DS2 method that exceeds the number of supported arguments generates a compilation error.

INT | BIGINT | SMALLINT | TINYINT
specifies an integer variable or array.

Alias INTEGER for INT

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DECIMAL[(*precision* [, *scale*])] | NUMERIC[(*precision* [, *scale*])]
specifies an exact numeric variable or array.

precision
specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

Note Not all data sources can support a precision of 52 digits.

scale
specifies the maximum number of decimal digits that can be stored to the right of the decimal point

Range 0–*precision*

Note *scale* is less than or equal to *precision*.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DOUBLE | DOUBLE PRECISION | FLOAT | REAL
specifies a floating-point variable or array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

BINARY (*length*)
specifies a binary variable or array.

Requirement If you specify BINARY, you must also specify the *length* of the variable or array in bytes.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

VARBINARY (*length*)
specifies a varying-length binary variable or array.

Alias BINARY VARYING

Requirement If you specify VARBINARY, you must also specify the *length* of the binary variable or array in bytes.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

NCHAR | NVARCHAR | CHAR | VARCHAR
specifies a character variable or array.

Aliases NATIONAL CHARACTER, NATIONAL CHAR for NCHAR

NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING for NVARCHAR

CHARACTER for CHAR

CHARACTER VARYING for VARCHAR

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

character-length
specifies the maximum number of characters that the string can hold for NCHAR, NVARCHAR, CHAR, and VARCHAR data types.

Default 8

Tip The number of bytes that character variables that are declared using CHAR use for storage depends on the session encoding. Those declared using any of the NCHAR variants have wider storage and can be used to represent character sets for which single-byte character storage is insufficient (for example, Unicode). If a session encoding requires multiple bytes per character (for example, UTF-8), then CHAR and NCHAR are identical types and both use NCHAR.

CHARACTER SET *character-set-identifier*
specifies character set encoding information for CHAR and VARCHAR data types.

Default Default encoding depends on your operating system and locale.

Tip You can use a character string literal or a simple string for character set names. For example, you can specify `"ibm-866"` or `'ibm-866'`

See For a complete list of character set encoding values, see "Encoding Values in SAS Language Elements" in the *SAS National Language Support (NLS): Reference Guide*.

TIME
specifies a time variable or array.

TIMESTAMP
specifies both a date and time variable or array.

precision
specifies the precision for a TIME or TIMESTAMP data type.

Default 6

Note If you are working with TIME and TIMESTAMP values in a data source other than SAS and you do not specify a precision, the default precision will always be the DS2 default precision of 6.

DATE
specifies a date variable or array.

variable
specifies the scalar variable or array name. You can specify one or more variables or arrays. However, *variable* can only be of the type specified in *data-type*. You can mix scalar and array variables of the same type.

RETURNS *data-type*
specifies the data type of the value that the method returns. The type can be any valid character, numeric, or date type.

Details

Method Basics

There are two types of methods in DS2: *system* methods, and *user-defined* methods. The METHOD statement enables you to create your own user-defined methods. For information about system methods, see "DS2 System Methods" on page 1457.

If a method returns a value, each RETURN statement that appears in the method must have an associated return expression. For more information, see the "RETURN Statement" on page 1425.

When a method definition appears after any method expression that refers to it, a FORWARD statement for the method must appear for the method before the method expression. User-defined methods that are not defined before the DS2 INIT, RUN, or TERM methods must be declared in a FORWARD statement. For more information, see the "FORWARD Statement" on page 1373.

Note: TINYINT and SMALLINT method parameters are automatically promoted to INTEGER, and REAL method parameters are automatically promoted to DOUBLE. A warning message appears. For more information, see "DS2 Type Conversions for Expression Operands" in *SAS DS2 Programmer's Guide*.

Passing Character Values to Methods

DS2's default parameter-passing semantics are pass-by-value. This means that a copy of the parameter is made and the copy is passed to the method, not the original parameter. Any changes to the parameter by the method are made to the copy and not to the original parameter. This ensures that the value of the original parameter is maintained for the caller of the method.

Given the potential size of character variables, the cost of making the copy, in terms of both memory and time, can be great. To avoid this cost, consider using the IN_OUT parameter, which causes the parameter to be passed-by-reference. This means that the location or address of the parameter is passed to the method, and a second copy of the parameter is not made. Changes that are made to the value of the parameter by the method, either intentional or unintentional, are reflected in any reference to the parameter by the caller after the method returns.

This syntax shows the two types of parameter passing:

```
/* pass-by-value */
method copy_made(char(256) x);
  ...
end;

/* pass-by-reference */
method no_copy(in_out char x);
  ...
end;
```

Returning Character Values from Methods

When a string value is returned by a method, DS2 creates a temporary string to hold the return value. There is a cost to copy the returned value from the temporary string to the target location. To avoid the cost of the copy, provide the target location of the return value with an IN_OUT parameter.

```
method copy_made() returns char(1024);
  return 'very long string';
end;

method no_copy(in_out char return_val);
  return_val = 'very long string';
end;
```

One benefit of passing the target location with an IN_OUT parameter is that the method does not need to specify the size of the returned string value at compilation.

Use Caution When Using the IN_OUT Parameter

The order in which subexpressions are evaluated is undefined for most DS2 operators. Therefore, using a variable more than once in an expression can produce unexpected results when the expression modifies the variable by passing it as an IN_OUT parameter to a method call. Here is an example.

```
method addValue( in_out integer i) returns integer;
    i = i + 100;
    return i;
 end;

 method init();
    X = 0;
   Y = addValue(X) + X;
end;
```

The order of evaluation is not defined for evaluating X in the expression `addValue(X) + X`. If the addValue(X) method call is evaluated before capturing the rightmost X value, the result is Y=200. If the rightmost X value is captured before the method call, the result is Y=100.

The easiest way to avoid the problem is to place the subexpression whose method call modifies X in a separate statement from the other subexpressions with X. Here is an example:

- If addValue(X) should be evaluated first, change `Y=addValue(X) + X;` in the code above. Here is the revised expression:

```
Y = addValue(X);
Y = Y + X;
```

- If addValue(X) should be evaluated last, change `Y=addValue(X) + X;`. Here is the revised expression:

```
Y = X;
Y = addValue(X) + Y;
```

Examples

Example 1: User-Defined Methods

In these three examples, M, CONCAT, and ADD are user-defined methods.

- ```
  method m(int x, int y) returns int;
     return x + y;
  end;
  ```

- ```
  method concat(char(100) x, char(100) y) returns char(200);
     return trim(x) || y;
  end;
  ```

- ```
  method add(double x, double y);
     this.x = this.x + x;
     this.y = this.y + y;
  end;
  ```

Example 2: Overloaded Methods

In the following examples, the D method and the CONCAT methods are overloaded. If any two method definitions have the same name, but different type signatures (that is, if the methods have different types), the method is overloaded.

```
method d(double x, double y) returns double;
   dcl double temp;
   temp = x * 99;
   return x + y + temp;
end;
method d(double x, int y) returns double;
   return x + y
end;
method d(int x);
   put x;
```
```

```
end;
method concat(char(100) x, char(100) y) returns char(200);
   return "pre" || trim(x) || y;
end;
method concat(char(100) x, char(100) y, char(100) z) returns char(200);
   return trim(x) || trim(y) || z;
end;
```

Example 3: Using the IN_OUT Argument

In the following example, the method *swapper* exchanges argument values. The IN_OUT argument enables the values to be changed where the method is called.

```
package xyzzy;
   method swapper(in_out double a, in_out double b);
      declare double x;
      x=a; a=b; b=x;
   end;
endpackage;
run;

data _null_;
   method init();
      dcl package xyzzy x();
      a=10; b=42;
      put 'before: ' a= b=;
      x.swapper(a,b);
      put 'after:  ' a= b=;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
before:  a=10 b=42
after:  a=42 b=10
```

Example 4: Passing in a Package as a Method Argument

In the following example, the *person_list* package contains the two methods *addP1* and *addP2*. The *addP1* and *addP2* methods each take the *person* package as an input parameter.

```
proc ds2;
  package work.person / overwrite=yes;
    declare varchar(32) lastname;
    declare varchar(32) firstname;
    method setNames(varchar(32) lastname_p, varchar(32) firstname_p);
      lastname = lastname_p;
      firstname = firstname_p;
    end;
    method getFullname() returns varchar(66);
      return (catx(', ', lastname, firstname));
    end;
  endpackage;
  package work.person_list / overwrite=yes;
```

```
    declare package work.person pl1;
    declare package work.person pl2;
    method addP1( package work.person pers_p);
      pl1 = pers_p;
    end;
    method addP2( package work.person pers_p);
      pl2 = pers_p;
    end;
    method getPersonList() returns varchar(256);
      return ( catx(':', pl1.getFullname(), pl2.getFullname()) );
    end;
  endpackage;
run;

  data new (overwrite=yes);
    declare char(66) myname;
    declare char(256) allNames;
      method init();
      declare package work.person pers1 ();
      declare package work.person pers2 ();
      declare package work.person_list pl ();
      pers1.setNames('Miller', 'Brad');
      pers2.setNames('Smith', 'Colin');
      myname = pers1.getFullname();
      pl.addP1(pers1);
      pl.addP2(pers2);
      allNames = pl.getPersonList();
      put myname=;
      put allNames=;
    end;
  enddata;
 run;
quit;
```

The following lines are written to the SAS log.

```
myname=Miller, Brad
allNames=Miller, Brad:Smith, Colin
```

Null Statement

Creates an empty statement.

Category: Local

Syntax

;

Details

The Null statement consists solely of a semicolon. It creates an empty statement.

Example

This example shows how the Null statement can be used to not execute any statements.

```
method init();
   x = 1;
   y = 0;
   z = 1;
   if x & y | not z then
      ;
   else
      put 'else';
end;
```

OUTPUT Statement

Writes the current row to a table.

Category: Local

Syntax

OUTPUT [{ *table* [... *table*] } | _ROWSET_ | _NULL_];

Without Arguments

Using OUTPUT without arguments causes the current row to be written to all tables that are named in the DATA statement or to the thread program. If no tables are specified in the DATA statement or to the thread program, then the row is written to the client application.

Optional Arguments

table

specifies the name of the table to which to write rows. *table* can be one of these forms.

- *catalog.schema.table-name*
- *schema.table-name*
- *catalog.table-name*
- *table-name*
- *caslib.table-name*

catalog is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

table-name is the name of the table.

caslib.table-name is the name of the table on the CAS server.

Restriction All names specified in the OUTPUT statement must also appear in the DATA statement.

Notes If the table name has a dot in it and you are accessing a CAS table, you must enclose the table name in double quotation marks. Here is an example:

```
data mycaslib "tdlibref.foo";
```

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double

quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in `data mytable;`, the table name is stored as "MYTABLE" and in `data "MyTable";`, the table name is stores as "MyTable". This is important if table and schema names in your data source are case-sensitive.

Tip You can specify up to as many tables in the OUTPUT statement as you specified in the DATA statement for that DS2 program.

CAUTION **Using the PRESERVE_TAB_NAMES=no option on your LIBNAME statement can cause unexpected results.**

ROWSET
specifies that the OUTPUT statement should not write rows to a table, but it should instead return table rows to the client application.

NULL
specifies that the OUTPUT statement should not write rows to either a table or the client application.

Details

When and Where the OUTPUT Statement Writes Rows

The OUTPUT statement creates an output row, using values for the row that are contained in the global variables when output statement executes. The OUTPUT statement writes the current row to a table immediately, not at the end of the DS2 program. If no table name is specified in the OUTPUT statement, the row is written to the table or tables that are listed in the DATA statement.

DS2 keeps track of the values in the order in which the compiler encounters them within a DS2 program, whether they are read from existing tables or created in the program.

Note: The MongoDB data source has special requirements for creating tables. Depending on your data, you might want to create these tables: a root table, a parent table, and a child table. You can create only root tables with DS2. To create parent and child tables, you must use FedSQL. See the information about MongoDB in *SAS/ACCESS for Relational Databases: Reference*.

Implicit versus Explicit Output

If you do not supply an OUTPUT statement, DS2 adds one implicitly at the end of the RUN method that writes rows to the table or tables that are being created.

Placing an explicit OUTPUT statement in a DS2 program overrides the automatic output, and adds a row to a table only when an explicit OUTPUT statement is executed. Once you use an OUTPUT statement to write a row to any one table, however, there is no implicit OUTPUT statement at the end of the RUN method. In this situation, a DS2 program writes a row to a table only when an explicit OUTPUT

statement executes. You can use the OUTPUT statement alone or as part of an IF-THEN/ELSE or SELECT statement or in DO loop processing.

Using the OUTPUT Statement in DS2 Program Threads

OUTPUT statements in thread programs cannot contain any table names. Each output row is returned to the thread program that started the thread.

Comparisons

- The OUTPUT statement writes rows to a table or to the client application; the PUT statement writes variable values or text strings to the SAS log.
- To control whenever a row is written to a table, use the OUTPUT statement. To control which columns are written to a table, use the KEEP= or DROP= table option in the DATA statement or use the KEEP or DROP statement.

Examples

Example 1: Sample Uses of OUTPUT

- This line of code writes the current row to a table.

```
output;
```

- This line of code writes the current row to a table when a specified condition is true.

```
if deptcode gt 2000 then output;
```

- This line of code writes a row to the MARKUP table when the PHONE value is missing.

```
if phone=. then output markup;
```

Example 2: Creating Multiple Rows from Each Row of Input

You can create two or more rows from each row of input data. This DS2 program creates three rows in the RESPONSE table for each row in the SULFA table:

```
data response(drop= (time1 time2 time3));
   method run();
      set sulfa;
      time=time1;
      output;
      time=time2;
      output;
      time=time3;
      output;
    end;
enddata;
```

Example 3: Creating Multiple Tables from a Single Input Table

You can create more than one table from one input table. In this example, OUTPUT writes rows to two tables, EASTERN and WESTERN:

```
data eastern western;
   method run();
      set cities;
      if location = 'east' then output eastern;
      else output western;
   end;
enddata;
```

Example 4: Creating One Row from Several Rows of Input

You can combine several input rows into one row. In this example, OUTPUT creates one row that totals the values of DEFECTS in the first ten rows of the input table:

```
data discards;
 drop defects;
   method run();
      set gadgets;
           reps+1;
      if reps=1 then total=0;
      total+defects;
      if reps=10 then do;
         output;
         stop;
       end;
   end;
enddata;
```

Example 5: Output Using Threads

The following example generates a result set of 20 random numbers. The data program starts 4 threads. Each thread generates and writes 5 random numbers with variable **x**. The data program reads the output of each thread with the SET statement and then writes the input random numbers to the data set **random_data**.

```
/* Thread generates and outputs 5 random numbers */
thread thread_pgm;
   declare double x;
   method init();
      declare int i;
      streaminit(_threadid_);
      do i = 1 to 5;
         x = rand('uniform', 1);
         output;               /* output variable x */
      end;
   end;
endthread;

 data random_data;
    dcl thread thread_pgm t;
    method run();
       /* Start 4 threads and read the output of each thread. */
       set from t threads=4;
```

```
    end;
enddata;
run;
```

The following output is generated.

The SAS System

PACKAGE Statement

Creates a DS2 package.

Category: Block

Syntax

Form 1: **PACKAGE** *package* [/ENCRYPT=SAS | AES] [/*table-options*];
... package-body ...
ENDPACKAGE;

Form 2: **PACKAGE** *fcmp-package-name* [/ENCRYPT=SAS | AES] [/*table-options*]
LANGUAGE=[']FCMP['] TABLE='*library-name*';
... package-body ...
ENDPACKAGE;

Required Arguments

package
specifies the package name. *package* can be one of these forms.

- *catalog.schema.package*
- *schema.package*
- *catalog.package*
- *package*

catalog
is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema
is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema

provides a grouping object that is used along with a catalog to provide a means of qualifying names.

package
is the name of the package.

Requirement Package naming conventions are based on the data source. For more information, see the documentation for your data source.

package-body
contains the declarations and methods in the package.

fcmp-package-name
specifies the name of the FCMP package.

Restriction This argument is not supported on the CAS server.

See "Using the FCMP Package" in *SAS DS2 Programmer's Guide*

'library-name'
specifies the name of the library where the FCMP function resides.

Restriction This argument is not supported on the CAS server.

Requirement This location must be the library.dataset portion of the location that was specified in the OUTLIB option in the PROC FCMP statement.

See The FCMP procedure in *Base SAS Procedures Guide*

Optional Arguments

/ENCRYPT=SAS | AES
specifies the encryption algorithm. SAS specifies the SAS Proprietary algorithm. AES specifies the Advanced Encryption Standard algorithm.

Default SAS

Interaction The ENCRYPT option for the PACKAGE statement is different from and has different values than the ENCRYPT= table option. The ENCRYPT= table option affects only SAS output data sets. For more information, see "ENCRYPT= Table Option" on page 1497.

/table-options
specifies optional arguments that the DS2 program applies when it creates a package. For more information about table options, see "DS2 Table Options" on page 1471.

Note Options that are not recognized by DS2 are passed without error to the underlying data source.

Details

Package Basics

A package is similar to a DS2 program. The package body consists of a set of global declarations and a list of methods. The main syntactical differences are the PACKAGE and ENDPACKAGE statements. These statements define a block with global scope. For more information about scope, see "Scope of DS2 Identifiers " in *SAS DS2 Programmer's Guide*.

The package's library of methods can be called from any other DS2 program including another package. Consequently, the INIT, RUN, and TERM methods have no special meaning in a package.

After successful compilation of a package, a copy of the package's source code is stored in the catalog entry that is identified by the package name.

The PACKAGE statement is required for all user-defined packages and for the FCMP package that is supplied by SAS. The hash, hash iterator, HTTP, JSON, logger, matrix, PCRXFIND, PCRXREPLACE, and SQLSTMT packages do not require a PACKAGE statement. These packages are also supplied by SAS. For more information, see "Introduction to DS2 Packages" in *SAS DS2 Programmer's Guide*.

Package variables are declared using the DECLARE PACKAGE statement. Declaring a package variable does not automatically construct an instance of a package. A package instance is constructed either by providing constructor arguments when a package variable is declared or by calling the _NEW_ operator.

By default, DS2 packages that are saved to a table for reuse are encrypted with SAS encryption. You can override this default and specify AES encryption by using the ENCRYPT= table option in the PACKAGE statement. SAS Proprietary is a fixed encoding algorithm that is included with SAS software For more information, see *SAS Viya Platform Encryption: Data at Rest*.

Table options can be specified in the PACKAGE statement. They are specified after the package name and preceded by a slash.

FCMP Packages

SAS provides an FCMP package that supports calls to FCMP functions and subroutines from within the DS2 language. For more information, see "Using the FCMP Package" in *SAS DS2 Programmer's Guide*.

Comparisons

For a comparison of packages, DS2 programs, and threads, see "Block Statements" on page 1309.

Examples

Example 1: Creating a Complex Number Package

This example creates a very simple complex number package. Two global variables, X and Y, represent the ordered pair of real numbers that constitute a complex number. This set of methods performs various operations on complex numbers, such as add and multiply.

```
package complex;
   dcl double x y;
  method init(double x, double y);
     this.x = x;
     this.y = y;
  end;
  method add(double x, double y);
     this.x = this.x + x;
     this.y = this.y + y;
  end;
  method mult(double x, double y);
     this.x = this.x * x - this.y * y;
     this.y = this.x * y + x * this.y;
  end;
  method norm() returns double;
     return sqrt(x ** 2 + y ** 2);
  end;
  method print();
     put 'x = ' x ' y= ' y;
  end;
endpackage;
run;
```

The following DS2 program instantiates and calls the methods defined in the previous PACKAGE statement.

```
data _null_;
   method init();
      dcl package complex c();
      dcl package complex c2();
      c.x=3;
      c.y=4;
      d = c.norm();
      put 'd= ' d;
      c.add(5, 6);
      c.print();
      c2.x=7;
      c2.y=24;
      d = c2.norm();
      put 'd= ' d;
      c2.print();
   end;
enddata;
run;
```

The following lines are written to the SAS log:

```
d=  5
x =  8  y=  10
d=  25
x =  7  y=  24
```

Example 2: Creating an FCMP Package

This example creates a square routine in FCMP and uses that routine in a DS2 program. The current directory is used as the "library" of FCMP packages.

```
libname base '.';

* fcmp defines a function, square;
proc fcmp outlib = base.fcmpsubs.package1;
   function square(a);
      return (a*a);
   endsub;
run;

* define the ds2 package thru which the fcmp functions will be called;
proc ds2;
package pkg /
   overwrite=yes
   language='fcmp'
   table='base.fcmpsubs';
run;

* call fcmp thru the ds2 wrapper package;
data;
   dcl package pkg p();
   dcl double a b;
   method init();
      do a = 10 to 20;
         b=p.square(a);
         put a= b=;
      end;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
a=10 b=100
a=11 b=121
a=12 b=144
a=13 b=169
a=14 b=196
a=15 b=225
a=16 b=256
a=17 b=289
a=18 b=324
a=19 b=361
a=20 b=400
```

Statements:

- "DECLARE PACKAGE Statement" on page 1338
- "DECLARE PACKAGE Statement: FCMP Package" on page 1651

PUT Statement

Prints the values of program variables, arrays, and constants to the SAS log.

Category: Local

Examples:
"Example 1: PUT Statements" on page 1415
"Example 2: Using PUT to Print Arrays" on page 1416
"Example 3: Using the _ALL_ Argument" on page 1417
"Example 4: Using PUT to Print Package Attributes" on page 1417

Syntax

PUT < put-list > [... <put-list>] ;

<put-list>::=

ALL

| '*character-string*'

| ['*character-string*']<eq-expression> [=] [[:] *format* [-L | -C | -R]]

<eq-expression>::=

identifier

| *array-reference*

| *this-expression*

| *package-attribute*

<package-attribute>::=

package-variable.*package-attribute*

| *package-variable*...[.*package-variableN*].*package-attribute*

Without Arguments

PUT without arguments prints a blank line to the SAS log.

Optional Arguments

ALL
prints the values of all variables, which includes predefined variables, to the SAS log.

'character-string'
specifies a string of text that is written to the SAS log.

identifier
names a variable whose value is written to the SAS log.

array-reference
specifies an array element. The subscript can be any SAS expression that resolves to an integer value when the PUT statement executes. Use the array subscript asterisk (*) to print all elements of the array.

this-expression
specifies a THIS expression.

See "THIS Expression" on page 2165

package-attribute
specifies an attribute of a package that is referenced by a package-variable using a dot operator. This attribute can be a scalar attribute, an array attribute, or the element of an array attribute of the package.

Restriction Dot notation is not supported in conjunction with the array subscript asterisk (*) to print all elements of the array.

package-variable
specifies an instance of a package. The name of the package instance must be followed by a dot operator and a package-attribute.

.
(dot operator) invokes a call to access the right-hand operand from the left-hand operand.

Requirement In the PUT statement, a package-variable must be specified as the left-hand operand of the dot operator. A package-attribute must be specified as the right-hand operand.

Interaction Dot notation enables you to print the value of a package attribute from code that is outside of the package. Nested dot notation enables you to print a package attribute from a package that is nested within a hierarchy of packages.

See "DOT Operator Expression" on page 2148

"Dot Notation in DS2 Packages" in *SAS DS2 Programmer's Guide*

=
If an equal sign is added after a variable or array element, then the output is preceded by the variable or array element name and an equal sign.

:
enables you to specify a format that the PUT statement uses to print the variable value. All leading and trailing blanks are deleted, and each value is followed by a single blank.

Restriction If you use ":", you must specify a format.

format
specifies a format to use when the data value is written to the SAS log. If you use a colon modifier (:) with the format name, all leading and trailing blanks are deleted and each value is followed by a single blank. To override the default alignment, you can add an alignment specification to a format:

-L left aligns the value.

-C centers the value.

-R right aligns the value.

Tip Ensure that the format width provides enough space to print the value and any commas, dollar signs, decimal points, or other special characters that the format includes.

Details

How to Use the PUT Statement

The PUT statement consists of the keyword PUT followed by a list of variables and character constants. You list the names of the variables whose values you want written, or you specify a character string in quotation marks. If you do not specify a format, the PUT statement prints a variable value with the default format, inserts a single blank, and then prints the next value. If you specify a format, the output is written using the format width. Character values are left-aligned in the field; leading and trailing blanks are removed. Numeric values are right-aligned in the field.

How nonexistent data (SAS missing values or null values) are written depends on whether you are in ANSI mode or SAS mode. A period is generated for DOUBLE missing dot and null values when the default format, BEST32., is associated with the DOUBLE. For special missing values (.a-.z and ._), the character after the period is generated when using BEST32.. For example, if a variable held the value .a, A would be generated. INTEGER and other non-DOUBLE numeric types cannot be missing. However, they can be null in which case nothing is generated by the PUT statement when the value is null. For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

How List Output Is Spaced

List output uses different spacing methods when it prints variable values and character strings. When a variable is written with list output, SAS automatically

inserts a blank space. The output pointer stops at the second column that follows the variable value.

```
dcl int a b;
dcl varchar c d;
area = 9924;
city = 1001;
ctry1='Peru';
ctry2='Bolivia';
    put area city ctry1 ctry2;
```

These lines are written to the SAS log.

```
----+----1----+----2
9924 1001 Peru Bolivia
```

However, when a character string is written, SAS does not automatically insert a blank space. The output pointer stops at the column that immediately follows the last character in the string.

To avoid spacing problems when both character strings and variable values are written, you might want to use a blank space as the last character in a character string.

If you use a colon modifier (:) with the format name, SAS prints the value with the specified format, inserts a blank space, and moves the pointer to the next column.

```
proc ds2;
data _null_;
  dcl int area POP;
  dcl varchar ctry1 ctry2;

  method init();
  area=9924;
  POP=1000;
  ctry1='Perú';
  ctry2='Bolivia';
  put area : octal10. pop : comma8.2 ctry1 ctry2;
  end;
 enddata;
run;
quit;
```

These lines are written to the SAS log.

```
----+----1----+----2----+----3----+
0000023304 1,000.00 Perú Bolivia
```

Formatted Output

You can use a format to control how SAS prints the variable values. The PUT statement uses the format that follows the variable name to print each value. With formatted output, SAS does not automatically add blanks between values. Formatted output moves the pointer the length of the format, even if the value does not fill that length. The pointer moves to the next column; an intervening blank is not inserted. If the value uses fewer columns than specified, character values are left-aligned and numeric values are right-aligned in the field that is specified by the format width.

```
dcl int a b;
dcl varchar c d;
pop = 1000
area = 9924;
ctry1='Peru';
ctry2='Bolivia';
put area octal10. pop comma8.2 ctry1 ctry2;
```

These lines are written to the SAS log.

```
----+----1----+----2----+----3----+
000000233041,000.00Peru Bolivia
```

If no format is specified, the variable's default format is used. You can associate a format with a column by using a HAVING clause in the DECLARE statement. For more information, see "DECLARE Statement" on page 1328.

Note: Default formats that are assigned to package attributes using the DECLARE statement HAVING clause are not applied when the PUT statement writes a package attribute value that is retrieved using dot notation. For more information, see "PUT Statement Functionality with Dot Notation" in *SAS DS2 Programmer's Guide*.

Comparisons

The PUT statement and the PUT function have similar behavior. However, the PUT statement directs its results to the SAS log whereas the PUT function returns an NCHAR value containing the result of formatting its argument.

Examples

Note: The DS2 statements in these examples are executed on the SAS Compute Server using the SAS DS2 procedure.

Example 1: PUT Statements

This example contains several PUT statements.

```
proc ds2;
 data _null_;
   dcl double x y z a[2];
   dcl varchar(3) s;

   method init();
   x = 1;
   y = 2;
   z = 3;
   s = 'abc';
   a[2] = 99;
```

```
    put 'x =' x;          /* 1 */
    put y=
    put z s a[2];         /* 2 */
  end;
enddata;
run;
quit;
```

1 This PUT statement specifies to print the variable name and value of variable x to the SAS log. Additional PUT statements request the same information for variables y and z. Because separate PUT statements are used, the information is written to a separate line in the SAS log.

2 This PUT statement specifies to print the values of variables z and s, and the second element of array a, without a preceding character string. All variable values are printed on the same line in the SAS log.

The following lines are written to the SAS log.

```
x =  1
y=2
3 abc 99
```

Note: When an equal sign is added after a variable or array element, the output is preceded by the variable or array element name and an equal sign. For example, these two code lines are equivalent.

```
put x= y= a[2]=;

put 'x='x ' y='y ' a[2]='a[2];
```

Example 2: Using PUT to Print Arrays

This example prints the contents of both temporary and variable arrays.

```
proc ds2;
data _null_;
   declare  double a[6] having format 4.1;
   vararray double b[2, 3];
   declare  double c[0:1, 2:4, 5:5];

   method init();
      a := (3 6 9 12 15 18);
      b := (3 6 9 12 15 18);
      c := (3 6 9 12 15 18);
      put a[*]=;    /* 1 */
      put b[*]=;
      put c[*]=;
      put 'array a with default format:' a[*];  /* 2 */
      put 'array a with best3.  format:' a[*] best3.;
   end;
enddata;
run;
quit;
```

1 Specifying the PUT statement with an asterisk subscript prints the values of all of an array's element to the SAS log.

2 The character string that precedes a variable or an array in the PUT statement can include any text. Unquoted text after the variable or array name in the PUT statement is applied as a format.

The following lines are written to the SAS log.

```
a[1]=3.00 a[2]=6.00 a[3]=9.00 a[4]=12.0 a[5]=15.0 a[6]=18.0
b[1,1]=3 b[1,2]=6 b[1,3]=9 b[2,1]=12 b[2,2]=15 b[2,3]=18
c[0,2,5]=3 c[0,3,5]=6 c[0,4,5]=9 c[1,2,5]=12 c[1,3,5]=15 c[1,4,5]=18
array a with default format: 3.00 6.00 9.00 12.0 15.0 18.0
array a with best3.  format:   3  6  9 12 15 18
```

Example 3: Using the _ALL_ Argument

This example uses the _ALL_ argument in the PUT statement to print the values of all variables, including the predefined _N_ variable, to the SAS log.

```
proc ds2;
data _null_;
  dcl double a b c;
  method init();
    a = 116;
    b = 220;
    c = 37;
    put _all_;
  end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
a=116 b=220 c=37 _n_=1
```

Example 4: Using PUT to Print Package Attributes

This example program shows how dot notation can be used to print data about package attributes.

```
proc ds2;
/* The package named information declares global variable age
 *  and constructor method information. */
package information / inline;
    declare int age;
    method information(int age);
      this.age = age;
    end;
endpackage;

/* The package named person declares a package-variable named
 * info, a global array variable named address, and
 * a constructor method named person. Package-variable info
 * is initialized to a null package reference. */
package person / inline;
    declare package information info;
    declare char(20) address[2];
    method person(int age);
```

```
      info = _new_ information(age);
    end;
endpackage;

data _null_;
   method run();
     declare package person a(15);       /* 1 */

     a.address[1] = '123 SAS Campus';    /* 2 */
     a.address[2] = '1 Main Street';

     put a.address[1]=;                  /* 3 */
     put a.address[2]=;

     put a.info.age=;
  end;
enddata;
run;
quit;
```

1 The data block's RUN method instantiates package `person` and assigns local variable `a` to reference the package `person` instance. During the instantiation of package `person`, the following implicit operations are performed:

- Package method `person` of package `person` is called with argument value 15.
- Package method `person` uses the _NEW_ operator to instantiate package `information`. Package `person`'s `info` attribute is assigned to reference the package `information` instance.
- During the package `information` instantiation, the value in parameter `age` of package method `person` is passed to package method `information`. There, it is assigned to package `information`'s `age` attribute.

2 Using dot notation, each assignment statement:

- gets the package `person` instance referenced by local variable `a` of the RUN method.
- gets the array attribute `address` from the `person` package instance.
- assigns a value to an element of the array attribute `address`.

3 Using dot notation, the PUT statement:

- gets the package `person` instance referenced by local variable `a` of the RUN method.
- gets the package `information` instance referenced by package attribute `info` from the package `person` instance.
- gets the value in package attribute `age` from the package `information` instance.
- writes the value to the SAS log.

Here is the output that is written to the SAS log:

```
a.address[1]=123 SAS Campus
a.address[2]=1 Main Street
a.info.age=15
```

RENAME Statement

Specifies new names for columns in output tables.

Category: Global

Syntax

RENAME *old-name* {= | AS} *new-name* [... *old-name* {= | AS} *new-name*];

Required Arguments

old-name
specifies the name of a column as it appears in the input table, or in the current DS2 program for newly created columns.

new-name
specifies the name to use in the output table.

Details

The RENAME statement enables you to change the names of one or more columns. The new column names are written to the output table only. Use the old column names in programming statements for the current DS2 program. RENAME applies to all output tables. In addition to changing the name of a column, the RENAME statement also changes the label for the column.

Comparisons

- The RENAME= table option enables you to specify the columns that you want to rename for each input or output table. Use it in input tables to rename columns before processing.
- If you use the RENAME= table option in an output table, you must continue to use the old column names in programming statements for the current DS2 program. The RENAME= table option affects only that output table. The RENAME statement affects all output tables.
- If you use both the RENAME statement and RENAME= output table option, the RENAME statement has precedence. If X is renamed to Y with a RENAME statement and X is renamed to Z with a RENAME= table option, the RENAME statement takes precedence and X is renamed to Y.
- The RENAME= table option in the SET statement renames columns in the input table. You must use the new names in programming statements for the current DS2 program.

Example

The following examples illustrate the RENAME statement.

- `rename prod=ProductName;`
- `rename street as Address cit as City st as State;`
- `rename oldsalary=newsalary;`

See Also

Table Option

- “RENAME= Table Option” on page 1531

RESIZEARRAY Statement

Sets or modifies the number of elements in a temporary array that has dynamic bounds.

Categories: Global
Local

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

Syntax

RESIZEARRAY *array-name* \[*n* \];

Required Arguments

array-name
specifies the name of an existing temporary array that has dynamic bounds.

\[*n*\]
specifies the upper bound for the array. The *n* argument can be an integer constant or an integer expression. For example, either of the following are valid:

```
RESIZE values[100]

RESIZEARRAY values[top+100];
```

Note The dimensions and lower bound of a dynamically bounded temporary array cannot be changed with the RESIZEARRAY statement.

Details

The RESIZEARRAY statement expands or contracts the number of elements in a dynamically bounded temporary array so that the array has *n* elements. After being resized, the array's lower bound is 1 and the array's upper bound is *n*.

When the array's bounds are resized more than once, the values of the array elements up to the less of the new and old number of elements remains unchanged. If the number of elements is expanded, the new elements are initialized to missing or null.

For global arrays, the RESIZEARRAY statement can be called only to resize the bounds of the array from methods within the package, thread, or data block that declared the global array.

For local arrays, the RESIZEARRAY statement can be called only to resize the bounds of the array from the method that declared the local array.

The RESIZEARRAY statement cannot change the bounds of an array argument, variable array, or temporary array that was declared with fixed bounds.

Example: Specifying the RESIZEARRAY Statement

The DECLARE statement defines a global temporary array with dynamic bounds named `b` of the binary type. The RESIZEARRAY statement assigns array `b` an upper bound of 10 elements.

```
1          proc ds2;
2          data _null_;
3            dcl binary(2) b[*] having format $hex.;
4            method init();
5              resizearray b[10];
6              b[1] = x'ABCD';
7              put b[1]=;
8            end;
9          enddata;
10          run;
11        !      quit;
b[1]=ABCD
```

Concepts:

- "Temporary Arrays" in *SAS DS2 Programmer's Guide*

Statements:

- "DECLARE Statement" on page 1328

RETAIN Statement

Specifies that all columns or all columns in the column list have their values retained between executions of the RUN method.

Category: Global

Syntax

Form 1: **RETAIN**;

Form 2: **RETAIN** *column-list*;

Form 3: **RETAIN** *column-list* < constant-value >;

Form 4: **RETAIN** *column-list* (< constant-value > ... < constant-value >);

< constant-value >::=

bit_constant

| *hex_constant*

| *floating_constant*

| *decimal_constant*

| *sas_missing_value*

| *integer_constant*

| *string_constant*

| *null*

| **DATE** *character_constant*

| **TIME** *character_constant*

| **TIMESTAMP** *character_constant*

Form 5: **RETAIN** *vararray*;

Without Arguments

(Form 1) If you do not specify any arguments, the RETAIN statement causes the values of all columns to be retained from one execution of the RUN method to the next.

Required Arguments

column-list
specifies column names whose values you want retained.

vararray
specifies the name of a variable array.

See "VARARRAY Statement" on page 1448

Details

Column Behavior (Form 2)

The RETAIN statement specifies that all columns in the column list should have their values retained during each execution of the RUN method. Normally, columns in the PDV are set to either a missing or null value before the RUN method executes.

Assigning Initial Values (Forms 3 and 4)

Use a RETAIN statement to specify initial values for individual columns, a list of columns, or members of an array. If a value appears in a RETAIN statement, columns that appear before it in the list are set to that value initially.

(Form 3) You can assign one value to all columns. For example, the following statement assigns a value of 100 to columns A, B, and C.

```
retain a b c 100;
```

(Form 4) You can assign different values to each column. For example, the following statement assigns the values 'Vancouver', 'BC', and 'Canada' to columns CITY, PROVINCE, and COUNTRY.

```
retain city province country ('Vancouver', 'BC', 'Canada');
```

Note that you can also use an iterator to assign one value to all columns. For example, the following statement assigns a value of 100 to columns A, B, and C.

```
retain a b c (3* 100);
```

(Form 5) You can assign initial values to the array variables. The RETAIN initializer works across array boundaries. In addition, if the initial list is short, the remaining values are set to missing values. In this example, the value of ns[3] is a missing value.

```
proc ds2;
data y /overwrite=yes;
   vararray double c[5];
   vararray double sums[dim(c)];
   vararray double ns[dim(c)];

   retain sums ns (1 2 3 4 5 6 7);
   method init();
      sums[4] = 99;
   end;

   method run();
      put sums[1]=;
      put sums[2]=;
      put sums[3]=;
      put sums[4]=;
      put sums[5]=;
      put ns[1]=;
      put ns[2]=;
      put ns[3]=;
   end;
enddata;
run;
quit;
```

Redundancy

It is redundant to name any of these items in a RETAIN statement, because their values are automatically retained from one iteration of the DS2 program to the next:

- columns that are read with a SET statement

  Note: It might not be redundant if multiple tables are associated with the SET statement. Assume that table **A** defines variable **X** but table **B** does not. Without a RETAIN statement, variable **X** is set to missing when records are read from table **B**. With a RETAIN statement, variable **X** has whatever value was last assigned to it by table **A** or by DS2 program logic.

- a column whose value is assigned in a sum statement
- data elements that are specified in an array

Comparisons

The RETAIN statement specifies columns whose values are preserved. The KEEP statement specifies columns that are to be included in any table that is being created.

See Also

Statements:

- "KEEP Statement" on page 1379

RETURN Statement

Returns execution from a method to the method caller.

Category: Local

Syntax

RETURN [*expression*];

Without Arguments

When a RETURN statement does not have an *expression*, control is transferred back to the caller of the method in which the RETURN statement is located. No value is returned to the caller of the method.

Optional Argument

expression
specifies any valid expression that returns a single value. The expression's type is evaluated, and if necessary, converted to the type specified in the METHOD statement's RETURNS clause. The value of *expression* is then passed back to the caller of the method.

Details

When the RETURN statement is executed in the implicit loop, the next iteration of the implicit loop executes. The RETURN statement transfers control and, if *expression* is present, returns a value back to the caller of the method. Any method that returns a value (in other words, that has a RETURNS clause in the METHOD statement) must have RETURN *expression* statement as the last statement in the METHOD body. Otherwise, an error occurs. A warning occurs if a method has a RETURN *expression* statement, but does not have a RETURNS clause.

You can use the STOP statement to terminate the RUN method.

Example

In this example, the CONCAT method returns a concatenated string. The RETURN statement's type is converted to the type of the RETURNS clause. In this example, the return type is CHAR.

```
method concat(char(100) x, char(100) y) returns char(200);
   return trim(x) || y;
end;
```

See Also

Statements:

- "METHOD Statement" on page 1391

SELECT Statement

Executes one of several statements or groups of statements.

Category: Local

Syntax

SELECT [(*select-expression*)];

[< when-list > [...< when-list>]] ;

[OTHERWISE *statement-list*] ;

END [*end-label*];

<when-list>::=

WHEN (*when-expression*) [*statement-list*]

Optional Arguments

select-expression
specifies an expression that evaluates to a single value of any type other than VARBINARY.

end-label
The END statement closes the SELECT statement. The optional *end-label* argument specifies an identifier. This label, created by using the Labels statement, must match the label immediately preceding the SELECT statement, or an error will occur.

when-expression
specifies any expression.

Requirement You must specify at least one *when-expression*.

statement-list
can be any executable statement or statements.

Details

Using WHEN Statements in a SELECT Group

The SELECT statement begins a SELECT group. SELECT groups contain WHEN statements that identify DS2 statements that are executed when a particular condition is true. Use at least one WHEN statement in a SELECT group. An optional OTHERWISE statement specifies a statement to be executed if no WHEN condition is met. An END statement ends a SELECT group.

Null statements that are used in WHEN statements cause no further action to be taken when the condition is true.

Note: SELECT statements can be nested.

Note: You can use a SELECT expression to select between multiple expressions based on the values of other expressions. For more information, see "SELECT Expression" on page 2166.

Note: In logical operations, any expression, including the WHEN statement, a missing value evaluates to False in SAS mode; a null value evaluates to neither true nor false in ANSI mode.

Evaluating the *when-expression* When a *select-expression* Is Included

If the *select-expression* is present, both the *select-expression* and *when-expression* are evaluated. The two are compared for equality and a value of true or false is returned. If the comparison is true, the *statement-list* is executed and processing exits the SELECT statement. No other conditions are tested.

If the comparison is false, execution proceeds to the next WHEN statement. If no WHEN statements remain, execution proceeds to the OTHERWISE statement, if one is present. If the result of all SELECT-WHEN comparisons is false and no OTHERWISE statement is present, no error is given and the DS2 program continues to execute.

Evaluating the *when-expression* When a *select-expression* Is Not Included

If no *select-expression* is present, the *when-expression* is evaluated to produce a result of true or false. If the result is true, the *statement-list* is executed and processing exits the SELECT statement. No other conditions are tested.

If the result is false, execution proceeds to the next WHEN statement, or to the OTHERWISE statement if one is present. (That is, the action that is indicated in the first true WHEN statement is performed.) If the result of all *when-expressions* is false and no OTHERWISE statement is present, an error message is issued. If more than one WHEN statement has a true *when-expression*, only the first WHEN statement is used. Once a *when-expression* is true, no other *when-expressions* are evaluated.

Evaluating the *when-expression* When a *statement-list* Is Not Included

If a *when-expression* appears without a *statement-list*, it uses the *statement-list* of the next *when-expression*. The following example produces an output of 10.

```
a = 10;
    select(a);
    when(10)
       when(20) put a=;
```

However, a *when-expression* without a *statement-list* breaks this behavior. This example produces no output.

```
a = 10;
    select(a);
    when(10) ;
    when(20) put a=;
```

Note: This is not true for a *when-expression* that precedes OTHERWISE. In this case, a *when-expression* without a statement is treated as if it has an empty statement (;).

Comparisons

Use IF-THEN/ELSE statements for programs with few statements. Use subsetting IF statements without a THEN clause to continue processing only those rows that meet the condition that is specified in the IF clause.

Examples

Example 1: SELECT with a select-expression

This example illustrates how to use the SELECT statement with a *select-expression*.

```
select (a);
   when (1) x=x*10;
   when (2);
   when (3) x=x*100;
   when (4) x=x*100;
   when (5) x=x*100;
   otherwise;
end;
```

Example 2: SELECT without a select-expression

This is an example of a SELECT statement without a *select-expression*.

```
select;
   when (mon in ('JUN', 'JUL', 'AUG')
   and temp>70) put 'SUMMER ' mon=;
   when (mon in ('MAR', 'APR', 'MAY'))
   put 'SPRING ' mon=;
   otherwise put 'FALL OR WINTER ' mon=;
end;
```

Example 3: SELECT without an IF Expression

This example uses a SELECT statement. You could also use IF expressions. IF expressions allow a more compact representation of calculations.

```
temp3=.;
select(age);
   when(12) temp3=0;
   when(13) temp3=-14.2769145744513;
   when(14) temp3=-27.3577925153955;
   when(15) temp3=-21.9485551871151;
   when(16) temp3=-13.1764092846992;
   when(17) temp3=-0.63898626243485;
end;
temp4=.;
select(sex);
   when('F') temp4=-1.47186167693037;
   when('M') temp4=1.47186167693037;
end;
temp5=.;
select(age);
   when(12) DO;
      select(sex);
         when('F') temp5=0;
         when('M') temp5=0;
      end;
   end;
   when(13) DO;
```

```
      select(sex);
         when('F') temp5=7.47012474340756;
         when('M') temp5=-7.47012474340756;
      end;
   end;
   when(14) DO;
      select(sex);
         when('F') temp5=4.35656087162482;
         when('M') temp5=-4.35656087162482;
      end;
   end;
   when(15) DO;
      select(sex);
         when('F') temp5=2.40720037896732;
         when('M') temp5=-2.40720037896732;
      end;
   end;
   when(16) DO;
      select(sex);
         when('F') temp5=7.56020843202274;
         when('M') temp5=-7.56020843202274;
      end;
   end;
   when(17) DO;
      select(sex);
         when('F') temp5=-0.0520606347702515;
         when('M') temp5=0.0520606347702515;
      end;
   end;
end;

predictedWeight = -182.556181904311 + temp3 + temp4 +
   4.85030791094268*height + temp5;
```

- “IF-THEN/ELSE Statement” on page 1376

SET Statement

Reads rows from one or more tables.

Category: Local

Note: Braces in the syntax convention indicate a syntax grouping. The escape character (\ ) before a brace indicates that the brace is required in the syntax. *sql-text* must be enclosed in braces ({ }).

Tips: A SET statement in a thread program shares a single reader for that SET statement. Each time a SET statement is executed, one row is read from the named input table. However, all threads share a single reader. Each row in the input table is sent to exactly one thread. If you use a SET statement in the INIT method, the first thread reads all the rows. The other threads reach end-of file, and processing is terminated without their advancing to their associated RUN methods. Consequently, it is recommended that you not use the SET statement in the INIT or TERM method of a thread program.

The width of the resulting column is determined by the largest width across all the tables on a single SET statement. Trailing blanks are irrelevant to the SET statement.

Syntax

SET < table-reference > [... < table-reference >] [INDSNAME=*variable*] ;

[BY [DESCENDING] *column* [... [DESCENDING] *column*]] ;

< table-reference>::=

{ *table* [(*table-options*)] }

| \{ *sql-text* \}

Required Arguments

table

specifies the name of an input table. *table* can be one of these forms.

- *catalog.schema.table-name*
- *schema.table-name*
- *catalog.table-name*
- *table-name*
- *caslib.table-name*

catalog is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

table-name is the name of the table.

caslib.table-name is the name of the table on the CAS server.

Restrictions DS2 does not have a WHERE table option. Use {*sql-text*} when you want to use a WHERE clause in the SET statement. See "Example 3: Specifying a WHERE Clause in the SET Statement" on page 1434.

DS2 does not have FIRSTOBS= and OBS= table options. Use {*sql-text*} when you want to specify row control options in the SET statement. See "Example 4: Specifying the Number of Rows That Are Processed" on page 1434.

Notes If the table name has a dot in it, you must enclose the table name in double quotation marks. Here is an example:

```
set "my.schema"."my.table";
```

If you do not use quotation marks around the table and schema names, DS2 stores them as uppercase and includes double quotation marks. Table and schema names that are enclosed in quotation marks are used as is. That is, they remain quoted and with the original casing in the quotation marks. For example, in `data mytable;`, the table name is stored as "MYTABLE" and in `data "MyTable";`, the table name is stored as "MyTable". This is important if table and schema names in your data source are case-sensitive.

CAUTION **Using the PRESERVE_TAB_NAMES=no option in your LIBNAME statement can cause unexpected results.**

{*sql-text*}
is any valid FedSQL code that resolves to a set of table rows.

Restriction The SQL in a SET statement can reference columns only if they are included in the data source table.

Requirement The FedSQL query must be enclosed in braces ({ }).

Tips You can use *sql-text* to merge rows from one or more tables.

The SQL in a SET statement is evaluated statically at compile time.

See The SELECT statement in *SAS FedSQL Language Reference*

Optional Arguments

INDSNAME=*variable*
creates and names a variable that stores the name of the table from which the current row is read. The stored name can be a table name or a physical name. The physical name is the name by which the operating environment recognizes the file.

Data type: NCHAR

Tips: Although the INDSNAME variable is automatically declared as NCHAR, you can explicitly declare it as CHAR.

Unless previously defined, the length of the variable is set to 41 characters. If the variable is declared as CHAR with a specific length, that length is not changed. If the value placed into the INDSNAME variable is longer than that length, then the value is truncated.

column
names each column by which the table is sorted.

Tip: The table can be sorted by more than one column.

table-options
specifies optional arguments that the DS2 program applies when it writes rows to the output table. For more information about table options, see "DS2 Table Options" on page 1471.

DESCENDING
specifies that the tables are sorted in descending order by the column that is specified. DESCENDING means largest to smallest for numeric columns, or reverse alphabetical for character columns.

Details

What SET Does

The SET statement is flexible and has a variety of uses in DS2 programming.

- reading rows and columns from existing tables for further processing in a DS2 program
- concatenating and interleaving tables, and performing one-to-one reading of tables

These uses are determined by the options and statements that you use with the SET statement:

Each time the SET statement executes, one row is read into the program data vector. SET reads all columns one row at a time from the input tables unless you specify otherwise. A SET statement can contain multiple tables; a DS2 program can contain multiple SET statements.

Note: A SET statement in a thread program shares a single reader for that SET statement. Each row in the input table is sent to exactly one thread.

Note: The SET statement is best used in the RUN method to take advantage of the RUN method's implicit looping capability.

Examples

Example 1: Reading a Table

In this example, each row in the table NC.MEMBERS is read into the program data vector. Only those rows whose value of CITY is `Raleigh` are written to the new table RALEIGH.MEMBERS:

```
data raleigh.members;
   method run();
      set nc.members;
      if city='Raleigh';
   end;
enddata;
run;
```

Example 2: Concatenating Tables

When more than one table name appears in the SET statement, the resulting output table is a concatenation of all the tables that are listed. SAS reads all rows from the first table, and then all rows from the second table, and so on, until all rows from all the tables have been read. This example concatenates the three tables into one output table named FITNESS:

```
data fitness;
   method run();
      set health exercise well;
   end;
enddata;
run;
```

Example 3: Specifying a WHERE Clause in the SET Statement

To submit a WHERE expression, you must specify a FedSQL SELECT statement in the SET statement.

```
data investment_history;
   method run();
      set {select * from investment where investment_year > 2010};
   end;
enddata;
run;
```

Example 4: Specifying the Number of Rows That Are Processed

To request a specified number of rows from the input table, specify the OFFSET and LIMIT clauses in a FedSQL SELECT statement. OFFSET specifies the number of rows to skip before the SELECT statement starts to return rows. LIMIT specifies the number of rows that the SELECT statement can return.

```
data test;
      method run();
        set {select * from employees offset 15 limit 10};
      end;
   enddata;
```

```
   run;
```

In this example, FedSQL returns 10 rows, beginning with row 15.

Example 5: Interleaving Tables

To interleave two or more tables, use a BY statement after the SET statement:

```
data april;
   method run();
      set payable recvable;
      by account;
   end;
enddata;
run;
```

Example 6: Combining a Single Row with All Rows in a Table

To combine a single row from one table with all rows from another table, use the SET statement in the INIT() method to select the single row. The SET statement in the INIT method is called once to read one row of data from the AVGSALES table. To obtain all the rows from the second table, use the SET statement in the RUN() method. The RUN() method has an implicit looping capability.

```
data national;
   method init ();
      set avgsales;
   end;
   method run();
      set totsales;
   end;
enddata;
run;
```

Resulting table NATIONAL contains data from one row of the AVGSALES table and data from all rows of the TOTSALES table.

Example 7: Reading from the Same SAS Data Set More Than Once

In this example, SAS treats each SET statement independently. That is, it reads from one SAS data set as if it were reading from two separate SAS data sets. The LOCKTABLE= table option is used in the first SET statement so that the same SAS data set (in this case, trial5) can be opened at the same time.

```
data drugxyz;
   method run();
      set trial5(locktable=share keep=(sample));
      if sample>2;
         set trial5;
   end;
enddata;
run;
```

For each iteration of the DS2 program, the first SET statement reads one row. The next time the first SET statement is executed, it reads the next row. Each SET statement can read different rows with the same iteration of the DS2 program.

Example 8: Specifying a Table Option in an Embedded SQL Statement

When reading from the same table more than once with FedSQL, the LOCKTABLE= table statement must be specified on both table references. Note that the FedSQL language has a different syntax for specifying table options from DS2.

```
data drugxyz;
   method run();
      set trial5 (locktable=share){select sample from trial5 {options locktable=share}
         where sample>2};
   end;
enddata;
run;
```

SET FROM Statement

Runs a DS2 program as one or more threads.

Category: Local

Restriction: Multiple SET FROM statements are not allowed in a data program. Otherwise, an error occurs.

Syntax

SET FROM *thread* [THREADS = *threads*];

Required Argument

thread
specifies the thread name that is executed by the SET statement. *thread* can be one of these forms.

- *catalog.schema.thread*
- *schema.thread*
- *thread*

catalog
is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema
is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema provides a grouping object that is used along with a catalog to provide a means of qualifying names.

thread
is the name of the thread.

Requirements The thread name must match the name of a thread created in a THREAD statement and the thread must be created before the SET FROM statement is executed, or an error will occur.

Thread naming conventions are based on the data source. For more information, see the documentation for your data source.

See "Threaded Processing" in *SAS DS2 Programmer's Guide*

Optional Argument

THREADS= *threads*
specifies the number of threads that are run for *thread*.

Restriction If you are using an FCMP package, the maximum value of *threads* is 100. Otherwise, there is no restriction on the value for *threads*.

Requirement *threads* must be an integer value.

Tip If *threads* is not present, the thread runs as a single thread.

Details

The Basics

The SET FROM statement enables a DS2 program to run as a single thread or as multiple threads. The thread name specified in a SET FROM statement references a DS2 program thread that has been created by a THREAD statement.

Note: The SET FROM statement is best used in the RUN method to take advantage of the RUN method's implicit looping capability.

Note: The MongoDB data source has special requirements for creating tables. Depending on your data, you might want to create these tables: a root table, a parent table, and a child table. You can create only root tables with DS2. To create parent and child tables, you must use FedSQL. See the information about MongoDB in *SAS/ACCESS for Relational Databases: Reference*.

THREADS= Argument and DS2 Threaded Programs in CAS

The basic computational model for analytics in SAS Cloud Analytic Services (CAS) combines distributed computing and multi-threaded computing. CAS actions that pass through the data typically do so by involving multiple threads: each thread receives a portion of the data, and each record in the input table is consumed by only one thread. These threads are called *worker threads* to emphasize the concurrent nature of their execution. The maximum number of concurrent worker threads that you are allowed to use is determined by your software license.

If your DS2 program specifies more threads than the maximum that you are allowed, DS2 reduces the number of threads to that maximum number. If your DS2 program either specifies 0 threads or does not specify the number of threads, DS2 uses the maximum number of threads allowed, as determined by your software license.

Comparisons

After the thread specified in SET FROM begins execution, the SET FROM statement executes similarly to the SET statement.

Similarities to note are:

- The PDV information for the thread is read by the DS2 program in which the SET FROM statement appears, so that all the output variables from the thread are declared automatically with correct types in the DS2 program.
- SET FROM and SET both loop through input until there are no more rows to read.

Here are differences to notice:

- Instead of reading from tables, the SET FROM statement reads the output from each of the threads.
- In general, the SET FROM statement's input consists of the stream of output produced by all the running threads, via the thread's OUTPUT statement. Because the execution order of threads is unpredictable, the input is not read sequentially like the SET statement reads tables. If the thread contains a SET statement that reads rows from tables, the rows are asynchronously divided among the threads. If a thread is not using a SET statement to read data, then the SET FROM statement's input is similar to reading one or more copies of a table, but with no given order on the incoming rows.

Examples

Example 1: Running a Single Thread

In this example, threads X and Y are automatically declared in the DS2 program with the appropriate types. When the SET FROM statement executes, T is started as a single thread, its rows are read, and a simple calculation is done for each.

```
thread work.t;
   dcl int x;
   dcl double y;
   method init();
      dcl int i;
      do i = 1 to 5;
         x = i;
         y = i * 2.5;
         output;
      end;
   end;
endthread;
data;
   dcl thread work.t t;
   method run();
      set from t;
      sum = x + y;
      put ' x= ' x ' y= ' y ' sum= ' sum;
   end;
enddata;
```

The following lines are written to the SAS log.

```
x=  1  y=  2.5   sum=  3.5
x=  2  y=  5     sum=  7
x=  3  y=  7.5   sum=  10.5
x=  4  y=  10    sum=  14
x=  5  y=  12.5  sum=  17.5
```

Example 2: Running Multiple Threads

This example modifies a thread, T, to run multiple threads by adding the THREADS option to the SET FROM statement.

```
thread work.t;
   dcl int x;
   dcl double y;
   method init();
      dcl int i;
      do i = 1 to 5;
         x = i;
         y = i * 2.5;
         output;
      end;
   end;
endthread;
data;
   dcl thread work.t t;
   method run();
      set from t threads=2;
      sum = x + y;
      put ' x= ' x ' y= ' y ' sum= ' sum;
   end;
enddata;
```

This runs two threads for T. The following lines are written to the SAS log.

```
x=  1  y=  2.5   sum=  3.5
x=  2  y=  5     sum=  7
x=  3  y=  7.5   sum=  10.5
x=  4  y=  10    sum=  14
x=  5  y=  12.5  sum=  17.5
x=  1  y=  2.5   sum=  3.5
x=  2  y=  5     sum=  7
x=  3  y=  7.5   sum=  10.5
x=  4  y=  10    sum=  14
x=  5  y=  12.5  sum=  17.5
```

In this case, the output is sequential, although there is no guarantee that will happen consistently.

Example 3: Accumulating Thread Values

In this example, the thread T generates a value of 1. In the DS2 program, four threads are started, and all output values are summed and printed in the TERM method.

```
thread t;
   dcl int x;
   method init();
      x = 1;
      output;
   end;
endthread;
data;
   dcl thread t t;
   dcl int sum;
   method init();
      sum = 0;
   end;
   method run();
      set from t threads=4;
```

```
      sum + x;
   end;
   method term();
      put 'sum= ' sum;
   end;
enddata;
```

The following line is written to the SAS log.

```
sum=  4
```

See Also

- "Threaded Processing" in *SAS DS2 Programmer's Guide*

Statements:

- "SET Statement" on page 1430
- "THREAD Statement" on page 1444

STOP Statement

Stops execution of the current DS2 program.

Category: Local

Syntax

STOP;

Without Arguments

The STOP statement causes processing of the current DS2 program to stop immediately and resume processing statements after the end of the current DS2 program.

Details

If DS2 generates a table, the row being processed when STOP executes is not added. The STOP statement can be used alone or in an IF-THEN/ELSE statement or SELECT group.

The TERM method always executes regardless of the method in which the STOP statement is executed. If you use the STOP statement in the TERM method, the TERM method will stop at the point where the STOP statement is executed.

If the STOP statement is executed in the INIT method or any method that is called from the INIT method, the RUN method does not execute.

Sum Statement

Adds or subtracts the result of an expression to an accumulator variable.

Category: Local

Note: The Sum statement can be used only with global variables. If you use the Sum statement with local variables, the values are not retained.

Syntax

variable + *expression*;

variable – *expression*;

Required Arguments

variable

specifies the name of the accumulator variable, which contains a numeric value.

Restrictions If you use an undeclared array in the Sum statement, an error occurs and a message is written to the SAS log.

The variable name cannot be “x”.

Tips The variable is automatically set to 0 before DS2 reads the first row. The variable's value is retained from one iteration to the next, as if it had appeared in a RETAIN statement.

To initialize a sum variable to a value other than 0, include it in a RETAIN statement with an initial value.

expression

is any valid DS2 expression.

Tip DS2 treats an expression that produces a missing or null value as zero.

See “DS2 Expressions” in *SAS DS2 Programmer's Guide*

Details

expression is evaluated and the result added to the accumulator variable. When the plus sign (+) is used, the result is added to the accumulator variable. When a minus sign (–) is used, the negative result is added to, in essence subtracted from, the accumulator variable.

Comparisons

The Sum statement is equivalent to using the SUM function and the RETAIN statement, as shown in this example.

```
retain variable 0;
variable=sum(variable,expression);
```

Examples

Example 1:

Here are examples of the Sum statement.

```
i + 2;
balance - debit;
numvalid + (not missing(x));
```

Example 2: Using the Sum Statement with Global and Local Variables

The following example uses both global and local variables in a Sum statement. Note that the value of the local variable, **x**, does not change.

```
data _null_;
  dcl int y;
   method m();
     dcl int x;
     x = 1;
     x + 2;
     y + 4;
     put x= y=;
   end;

   method init();
    do i = 1 to 3;
      m();
    end;
   end;
enddata;
run;
```

The following lines are written to the SAS log:

```
x=3 y=4
x=3 y=8
x=3 y=12
```

THREAD Statement

Creates a DS2 program thread.

Category: Block

Restrictions: Thread parameters in the THREAD statement and the SETPARMS method are not supported on the CAS server.

Package types are not supported as parameters in the THREAD statement. A DS2 thread can instantiate a local instance of a package within the thread program. The package instance is not accessible from any other DS2 thread, and data is not shared across threads. If the DS2 program spawns 10 DS2 threads, then there are 10 package instances in memory.

Syntax

THREAD *thread* [(*data-type variable* [, ... *data-type variable*])]
[/ENCRYPT=SAS | AES] [/*table-options*];

... *thread-body* ...

ENDTHREAD;

Required Arguments

thread
specifies the thread name. *thread* can be one of these forms.

- *catalog.schema.thread*
- *schema.thread*
- *catalog.thread*
- *thread*

catalog
is an implementation of the ANSI SQL standard for an SQL catalog, which is a data container object that groups logically related schemas. The catalog is the first-level (top) grouping mechanism in a data organization hierarchy that is used along with a schema to provide a means of qualifying names.

schema
is an implementation of the ANSI SQL standard for an SQL schema, which is a data container object that groups files such as tables and views and other objects supported by a data source such as stored procedures. The schema

provides a grouping object that is used along with a catalog to provide a means of qualifying names.

thread
is the name of the thread.

Requirement Thread naming conventions are based on the data source. For more information, see the documentation for your data source.

thread-body
contains the declarations and methods in the thread.

Optional Arguments

data-type
is an optional data type declaration. For more information, see "DS2 Data Types" in *SAS DS2 Programmer's Guide*.

variable
names an optional variable that identifies the parameter.

Restriction Thread parameters in the THREAD statement are not supported on the CAS server.

/ENCRYPT=SAS | AES
specifies the encryption algorithm. SAS specifies the SAS Proprietary algorithm. AES specifies the Advanced Encryption Standard algorithm.

Default SAS

Interaction The ENCRYPT option for the THREAD statement is different from and has different values from the ENCRYPT= table option. The ENCRYPT= table option affects only SAS output data sets. For more information, see "ENCRYPT= Table Option" on page 1497.

/table-options
specifies optional arguments that the DS2 program applies when it creates a thread. For more information about table options, see "DS2 Table Options" on page 1471.

Details

A DS2 thread begins with the THREAD statement and ends with the ENDTHREAD statement. These statements define a block with global scope. For more information about global scope, see "Scope of DS2 Identifiers " in *SAS DS2 Programmer's Guide*.

The thread body consists of a set of global declarations and a list of methods. You can specify the number of threads used by a thread program by using the SET FROM statement.

A DS2 program processes input data and produces output data. A DS2 program can run in two different ways: as a program and as a thread. When a DS2 program runs as a program, here are the results:

- Input data can include both rows from database tables and rows from DS2 program threads.
- Output data can be either database tables or rows that are returned to the client application.

When a DS2 program runs as a thread, here are the results:

- Input data can include only rows from database tables, not other threads.
- Output data includes the rows that are returned to the DS2 program that started the thread.

For more information about threads, see "Overview of Threaded Processing" in *SAS DS2 Programmer's Guide*.

A DS2 thread must be given a name. This name identifies a catalog entry in which the thread's source code is stored after it successfully compiles. Other DS2 programs and threads can then read and execute the thread by using the SET FROM statement.

When a thread is declared, a table is created with the name of the thread. A note is written to the SAS log that indicates that a table was created and where it was created, typically to the Work library. In most situations, a single-level named table does not persist after a SAS session ends. However, some single-level named tables do persist. Tables with multi-level names always persist after a SAS session. If a thread persists, it can be executed multiple times without having to redeclare the thread. You can add a DROP THREAD statement to your program to clean up unwanted tables.

Threads are declared for use in a DS2 program by using the DECLARE THREAD statement. When you declare a thread, the variable representing the thread is considered an instance of the thread. Thread variables can appear only in global scope. Otherwise, an error occurs. For more information about instantiating a thread, see the DECLARE THREAD statement.

Note: If variables are declared with a HAVING clause in a thread program and the variables are redeclared in a data program with a HAVING clause, the HAVING clause in the data program is used instead of the HAVING clause in the thread program. If there is no HAVING clause in the DECLARE statement in the data program, the HAVING clause in the thread program is not used.

Threads can have parameters, as in this example:

```
thread work.t (double d, char (100) sp);
```

When you are using parameterized threads, the parameter names and their types are specified in the THREAD statement. The DS2 program that calls the thread must initialize the thread's parameters by calling the SETPARMS method. In this example, the parameter D is initialized with a value of *99* and the parameter SP is initialized with a value of *'ijk'*.

```
t.setparms(99, 'ijk');
```

By default, DS2 threads are encrypted with SAS encryption. You can override this default and specify AES encryption by using the ENCRYPT table option in the THREAD statement. SAS Proprietary is a fixed encoding algorithm that is included with SAS software. For more information, see *SAS Viya Platform Encryption: Data in Motion*.

Table options can be specified in the THREAD statement. They are specified after the package name and preceded by a slash.

Comparisons

For a comparison between packages, DS2 programs, and threads, see "Block Statements" on page 1309.

Examples

Example 1: Simple Thread

In this example, a single thread is created by using the THREAD statement.

```
thread t;
   dcl int x;
   method init();
      x = 99;
      output;
   end;
endthread;
```

Example 2: Running Multiple Threads

This example modifies a thread, T, to run multiple threads by adding the THREADS option to the SET FROM statement.

```
thread work.t;
   dcl int x;
   dcl double y;
   method init();
      dcl int i;
      do i = 1 to 5;
         x = i;
         y = i * 2.5;
         output;
      end;
   end;
endthread;
data;
   dcl thread work.t t;
   method run();
      set from t threads=2;
      sum = x + y;
      put ' x= ' x ' y= ' y ' sum= ' sum;
```

```
   end;
enddata;
```

This runs two threads for T. The following lines are written to the SAS log.

```
x=  1  y=  2.5   sum=  3.5
x=  2  y=  5     sum=  7
x=  3  y=  7.5   sum=  10.5
x=  4  y=  10    sum=  14
x=  5  y=  12.5  sum=  17.5
x=  1  y=  2.5   sum=  3.5
x=  2  y=  5     sum=  7
x=  3  y=  7.5   sum=  10.5
x=  4  y=  10    sum=  14
x=  5  y=  12.5  sum=  17.5
```

In this case, the output is sequential, although there is no guarantee that will happen consistently.

VARARRAY Statement

Declares one or more DS2 variable arrays.

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

Syntax

VARARRAY <data-type> *array-name* <array-declaration> [<variable-list>] [<having-clause>];

< data-type >::=

<exact-numeric-type> | <approximate-numeric-type> | <binary-string-type> | <string-type>

| <date-type>

<exact-numeric-type> ::=

{**INT** | **BIGINT** | **SMALLINT** | **TINYINT**
| **DECIMAL** [(*precision* [,*scale*])] | **NUMERIC** [(*precision* [,*scale*])] }

<approximate-numeric-type> ::=

{ **DOUBLE** | **DOUBLE PRECISION** | **FLOAT** | **REAL** }

<binary-string-type>::=

BINARY(*length*) | **VARBINARY**(*length*)

<string-type>::=

NCHAR [(*character-length*)]

| **NVARCHAR** [(*character-length*)]

| **CHAR** [(*character-length*)] [**CHARACTER SET** *character-set-identifier*]

| **VARCHAR** [(*character-length*)] [**CHARACTER SET** *character-set-identifier*]

<date-type>::=

{ **TIME** | **TIMESTAMP** } [(*precision*)] | **DATE**

<array-declaration::=\[array-bound>[, ...<array-bound>]\

<array-bound>::= {[*dim-lower*:]*dim-upper*} | {[*dim-lower*:] {DIM(*a*[, *n*]) | *} }

<variable-list>::=

name-varlist |
| *numbered-range-varlist*
| *name-range-list*
| *name-prefix-list*
| *type-varlist*
| *special-name-list*

<having-clause>::=

HAVING <having-option> [... <having-option>]

<having-option>::=

LABEL '*string*' | n'*string*'

| **FORMAT** *format*

| **INFORMAT** *format*

Required Arguments

INT | BIGINT | SMALLINT | TINYINT
specifies an integer array.

Alias INTEGER for INT

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

| DECIMAL[(*precision* [, *scale*])] | NUMERIC[(*precision* [, *scale*])]
specifies an exact numeric variable or array.

precision
specifies the maximum total number of decimal digits that can be stored, both to the left and to the right of the decimal point

Note Not all data sources can support a precision of 52 digits.

scale
specifies the maximum number of decimal digits that can be stored to the right of the decimal point

Range 0–*precision*

Note *scale* is less than or equal to *precision*.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

DOUBLE | DOUBLE PRECISION | FLOAT | REAL
specifies a floating-point array.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

BINARY (*length*)
specifies a binary variable or array.

Requirement If you specify BINARY, you must also specify the *length* of the variable or array in bytes.

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

VARBINARY (*length*) | BINARY (*length*)
specifies a fixed-length or varying-length binary array.

Alias BINARY VARYING

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

NCHAR | NVARCHAR | CHAR | VARCHAR
specifies a character array.

Aliases NATIONAL CHARACTER, NATIONAL CHAR for NCHAR

NATIONAL CHARACTER VARYING, NATIONAL CHAR VARYING for NVARCHAR

CHARACTER for CHAR

CHARACTER VARYING for VARCHAR

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

TIME
specifies a time array.

TIMESTAMP
specifies both a date and time array.

DIM(*a*[, *n*])
specifies that the size of the upper bounds of the array is determined by the number of elements in a dimension of a previously declared array by using a DIM function call.

a
specifies the name of a previously declared array.

n
specifies the dimension, in a multidimensional array, for which you want to know the number of elements.

Tip If no *n* value is specified, the DIM function returns the number of elements in the first dimension of the array.

Restriction The DIM function is the only function that you can use to specify an upper array bounds. The DIM function cannot be used to specify the lower bound of a dimension.

See "DIM Function" on page 523

*
specifies a one-dimensional array in which the lower bound is 1 and the upper bound is the number of variables in the variable list.

Requirement You must specify at least one *variable* in the variable list.

Optional Arguments

character-length
specifies the maximum number of characters that the string can hold for NCHAR, NVARCHAR, CHAR, and VARCHAR data types.

Default 8

Requirement All character variables in a character variable array must have the same length.

CHARACTER SET *character-set-identifier*
specifies character set encoding information for CHAR and VARCHAR data types.

Default Default encoding depends on your operating system and locale.

Requirement All character variables in a character variable array must have the same encoding.

Tip You can use a character string literal or a simple string for character set names. For example, you can specify `"ibm-866"` or `'ibm-866'`

See For a complete list of character set encoding values, see "Encoding Values in SAS Language Elements" in the *SAS National Language Support (NLS): Reference Guide*.

precision
specifies the precision for a TIME or TIMESTAMP data type.

Default 6

Note If you are working with TIME and TIMESTAMP values in a data source other than SAS and you do not specify a precision, the default precision will always be the DS2 default precision of 6.

DATE
specifies a date array.

dim-lower* and *dim-upper
specifies a positive or negative integer used to define the number and size of the array boundary.

Tip If the lower bound of a dimension is not specified, then the lower bound defaults to 1.

See "Variable Array Declaration" in *SAS DS2 Programmer's Guide*

<variable-list>
specifies the name of the variable(s) that is to be referenced by the elements of the array.

Requirement *variable* must be the same type specified in *data-type*.

Tip You can specify one or more variables.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

LABEL | '*string*' | n'*string*'
assigns a descriptive label to the variable array. The label can be a CHAR literal (*string*) or NCHAR literal (n*string*).

See "DS2 Data Types" in *SAS DS2 Programmer's Guide*

FORMAT *format*
Associates any valid DS2 format with the variable or array.

See "DS2 Formats" on page 61

INFORMAT *informat*
Associates any valid SAS informat with the variable or array.

See Chapter 8, "DS2 Informats," on page 1299

Details

You use the VARARRAY statement to create a variable array. A variable array is a temporary grouping of global variables. Only one array can be specified in a VARARRAY statement.

Variable arrays exist only for the duration of the DS2 program.

The different forms of variable lists can be mixed within a single variable list specification. For example, `vararray double a[*] u x1-x3 u:;` is a valid statement.

The above variable list would expand to `u x1 x2 x3 u u1 u2`. Therefore, a seven-element variable array would be constructed. Note that a single variable can be referenced by multiple elements of a variable array.

For more information, see "DS2 Arrays" in *SAS DS2 Programmer's Guide* and "Variable Arrays" in *SAS DS2 Programmer's Guide*.

For information about how to create a temporary array, see "DECLARE Statement" on page 1328.

Example

The following table contains examples of statements that specify variable arrays and the dimensions of those arrays.

Statement	Number of Dimensions	Range of Each Dimension	Number of Elements	Referenced Variables
`vararray double a[100];`	1	1:100	100	a1...a100
`vararray double a[2, 2];`	2	1:2 1:2	4	a1 a2 a3 a4
`vararray double a[-3:3, 5, 7:9, 10];`	4	-3:3 1:5 7:9 1:10	7x5x3x10 = 1050	a1 ... a1050
`vararray double a[3] x y z;`	1	1:3	3	x y z
`vararray double a[3] c3-c1;`	1	1:3	3	c3 c2 c1
`vararray double a[2, 2] t u v w;`	2	1:2 1:2	4	t u v w
`vararray double a[2, 2, 2] u v2-v4 w1-w3 x;`	3	1:2 1:2 1:2	8	u v2 v3 v4 w1 w2 w3 x
`vararray double a[*] x y z;`	1	1:3	13	x y z
`vararray double a[*] a1-a10;`	1	1:10	10	a1...a10

Statements:

- “DECLARE Statement” on page 1328

VARLIST Statement

Creates a named variable list.

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

Syntax

VARLIST *list-name* \[*variable-list*\];

Required Arguments

list-name
specifies the name of the variable list.

[*variable-list*]
specifies the variables that are to be referenced by the list.

Requirement The *variable-list* must be enclosed in brackets ([]).

Details

Note that the VARLIST statement is limited to the global scope of the DS2 package or program. The VARLIST statement cannot be used to create a local variable list.

Examples

Example 1: Variable List That Contains All Variables in the PDV

In this example, the VARLIST statement creates a variable list named **allvars**, which contains all the PDV variables in the DS2 program.

```
varlist allvars [_all_];
```

Example 2: Initializing the Data Values in a Variable List

In this example, the variable list, c3, is declared and then initialized in the INIT method.

```
data;
   declare int cost1 cost2 cost3 cost4 cost5;
   varlist c3 [cost1-cost5];

   method init();
      cost1 = 1;
      cost2 = 2;
      cost3 = 3;
      cost4 = 4;
      cost5 = 5;
   end;
enddata;
run;
```

Example 3: Using a VARLIST to Create a Local Variable List Causes an Error

In this example, the VARLIST statement causes the following error to appear: `Invalid variable list. vars is not a global scalar variable.` The VARLIST statement cannot be used to create a local variable list.

```
data _null_;
   declare double a;
   varlist vars [a];
   vararray double y[1] vars;  /* Error: varlist variable */
enddata;
run;
```

Example 4: Passing a Variable List to a Function That Accepts a Variable List Argument

The following example creates a method, printNames, that contains a variable list, v. The variable list, v, is passed into the VNAME and VTYPE functions.

```
data _null_;
   vararray double x[5];
   dcl bigint xyz;
   dcl date xanadu;

   method printNames(varlist v);
      dcl varchar(100) name type;
      dcl bigint i;
      do i = 1 to dim(v);
         name = vname(v[i]);
         type = vtype(v[i]);
         put name= type=;
      end;
   end;

   method init();
      printNames([x:]);
   end;
enddata;
run;
```

The following lines are written to the SAS log:

```
name=x1 type=double
name=x2 type=double
name=x3 type=double
name=x4 type=double
name=x5 type=double
name=xyz type=bigint
name=xanadu type=date
```

DS2 System Methods

Overview of System Methods

Methods are basic program execution units. A method defines a scoping block, so any parameters and any variable declarations in the method body are local to the method. In DS2, all program code must reside in some method.

System methods have a preset meaning in DS2. There are three system methods: INIT, RUN, and TERM. These methods cannot be overloaded. There is one optional system method that is used only with threads: SETPARMS.

The following table lists and summarizes the purpose of each DS2 system method.

System Method	Execution Details	Purpose
INIT( )	Automatically executes one time, as the first method of a program.	As the name implies, INIT( ) is a good place to initialize global program variables. Most global variables are not initialized by the system. However, the system does initialize predefined variables, such as _N and _N_, and variables that are used in Sum and RETAIN statements. If your program does not require the capabilities of the other system methods, you can code your entire program in the INIT( ) method. Just add DS2 statements, including but not limited to the following:

System Method	Execution Details	Purpose
		■ DECLARE statements to create method-scope local variables ■ Calls to one or more user-defined methods ■ DS2 statements that perform variable assignments, call DS2 functions, execute loops or other logic, and so on For more information, see "INIT Method" on page 1459.
RUN( )	Automatically executes after INIT( ) completes.	The RUN( ) method is the functional equivalent of the DATA step. That is, if your RUN( ) method contains a SET statement, the method runs as an implicit loop. You can also use RUN( ) to read rows from a thread program using the SET FROM statement. **Note:** You are not required to include code that leverages the implicit loop capabilities. If appropriate, you can code your entire program in the RUN( ) method, as described for INIT( ). For more information, see "RUN Method" on page 1460.
TERM( )	Automatically executes one time, as the last method of a program.	As the name implies, TERM( ) is where final processing takes place, before the program exits. TERM( ) automatically resets global variables to uninitialized values, with the following exceptions: ■ predefined variables, such as _N and _N_ ■ accumulator variables that were used in Sum statements ■ variables that were used in a RETAIN statement ■ package variables If appropriate, you can code your entire program in the TERM( ) method, as described for INIT( ). For more information, see "TERM Method" on page 1464.
SETPARMS( )	Executes one time, when called from a data program, to initialize the values of a parameterized thread.	SETPARMS( ) initializes the values of a parameterized thread. Because only parameterized thread programs require this, SETPARMS( ) is the only system method that must be called. **Note:** Do not write a SETPARMS( ) method in your thread program. The system supplies the method for you. **Note:** Do not call SETPARMS( ) more than once. The initialization works only the first time. For more information, see "SETPARMS Method" on page 1462.

For complete information about how methods work in DS2, see "Methods" in *SAS DS2 Programmer's Guide*.

Dictionary

INIT Method

Calls a DS2 system method where program initializations can take place.

Syntax

METHOD INIT( );
END;

Without Arguments

The METHOD INIT statement has no arguments. If you try to pass arguments, an error occurs.

Details

Typically, the INIT method contains any initialization code such as variable initialization or opening of tables. Code in the INIT method runs once at the beginning of the DS2 program.

Every DS2 program contains, either implicitly or explicitly, the INIT, RUN, and TERM methods. If you do not specify a METHOD INIT statement, DS2 automatically provides one.

For more information about the INIT method and how DS2 programs work, see "Methods" in *SAS DS2 Programmer's Guide*.

Example

```
method init();
   dcl int i;
   dcl double d;
   d = 99;
   do i = 1 to 3;
      d = d + i;
      output d;
   end;
```

```
end;
```

See Also

- "Methods" in *SAS DS2 Programmer's Guide*

Methods:

- "RUN Method" on page 1460
- "TERM Method" on page 1464

RUN Method

Calls a DS2 system method where DS2 program code can run in an implicit loop.

Syntax

METHOD RUN( );
END;

Without Arguments

The METHOD RUN statement has no arguments. If you try to pass arguments, an error occurs.

Details

Typically, the RUN method contains the main DS2 program code. The RUN method has the same feature of automatic, implicit looping as the SAS DATA step. After the RUN method has been executed one time, the RUN method either runs again or control is passed to the TERM method.

Every DS2 program contains, either implicity or explicitly, the INIT, RUN, and TERM methods. If you do not specify a METHOD INIT or METHOD TERM statement, DS2 automatically provides one.

After the INIT method runs and before the RUN method is executed, variables in the program data vector, which have not been retained (by using the RETAIN statement), are set to either SAS missing values or null values depending on whether you are in SAS mode or ANSI mode.

Local variables in the RUN method completely cease to exist between invocations of RUN in the implicit loop. For each invocation of the RUN method, all local

variables are constructed at the start of execution of the method and destroyed at end of execution of the method. All global variables, except column variables read by the SET statement, are set to missing or null between each iteration (RUN method invocation) of the implicit loop. To retain state data through the implicit loop, you must create a global variable AND also specify that the variable's value be retained across executions of the RUN method with the RETAIN statement. The RUN method is executed *x*+1 times for a table with *x* rows. If a SET statement is executed and finds no more rows, then the implicit looping of the RUN method ceases.

For more information about SAS and ANSI mode, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

For more information about the RUN method and how DS2 programs work, see "Methods" in *SAS DS2 Programmer's Guide*.

Comparisons

In DATA step programming, the entire DATA step represents the implicit loop. In the DS2 language, the implicit loop is represented by the RUN method.

Example

DS2's flow of execution is to call the INIT method once, then the RUN method until the input tables are completely read, then the TERM method. The RUN method is where the implicit loop exists. The following program demonstrates this flow of control by finding the minimum of values in a table. The INIT method initializes the columns used to find the current minimum, the RUN method compares input values with the current minimum, and the TERM method writes the minimums to an output table.

```
data xy_data;
   dcl double x y;
   method init();
      do x = 1 to 5;
         y = 2*x;
         output;
      end;
   end;
enddata;
run;
/* Find the minimum value for x and y */
data xy_mins;
   dcl double min_x min_y;
   retain min_x min_y;
   keep min_x min_y;
   method init();
      min_x = 999999;
      min_y = 999999;
   end;
   method run();
```

```
      set xy_data;
      if x < min_x then min_x = x;
      if y < min_y then min_y = y;
   end;
   method term();
      output;
   end;
enddata;
run;
/* Send result table of minimums to output */
data;
    method run();
       set xy_mins;
    end;
enddata;
run;
```

- "Methods" in *SAS DS2 Programmer's Guide*

Methods:

- "INIT Method" on page 1459
- "TERM Method" on page 1464

SETPARMS Method

Initializes parameters for an instance of a DS2 thread.

Restriction: This method is not supported on the CAS server.

Syntax

thread.**SETPARMS**(*parameter-value*[, ...*parameter-value*]);

Required Arguments

thread
specifies an instance of the thread.

parameter-value
specifies the initial value of the thread parameter.

Details

When using parameterized threads, the parameter names and their types are specified in the THREAD statement. The DS2 program that invokes the thread must initialize the thread's parameters by calling the SETPARMS method. In this example, assume you have an instance of the thread, T, that takes two parameters, INV and PROD.

```
thread work.t (double inv, char (30) prod);
```

Using the SETPARMS method, the parameter INV is initialized with a value of *38824* and the parameter PROD is initialized with a value of *'rice'*.

```
t.setparms(38824, 'rice');
```

Each argument is passed by value to the corresponding thread parameter. All arguments are converted, if necessary, to the data type of the corresponding parameter. If the SETPARMS method is called for a thread, which has no parameters, an error occurs.

The SETPARMS method must be called to initialize parameters for a thread before the thread's SET FROM statement executes, or the parameters initialize with SAS missing values or null values, depending on whether you are in SAS mode or ANSI mode. For more information, see "How DS2 Processes Nulls and SAS Missing Values" in *SAS DS2 Programmer's Guide*.

Example

This example illustrates how to use threads with parameters.

```
thread work.t (double d, char (100) sp);
   dcl int x;
   dcl double y;
   dcl nchar(20) s;
   dcl char(30) c;
   method init();
      dcl int i;
      s = 'abc' || sp;
      c = 'uvwxyz' || sp;
      do i = 1 to 100;
         x = i;
         y = i * 2.5 + d;
         output;
      end;
    end;
endthread;
run;
data;
   dcl thread work.t t;
   method init();
      t.setparms(99, 'ijk');
   end;
   method run();
      set from t;
```

```
      answer = x + y;
      put 's= ' s ' x= ' x ' y= ' y ' c= ' c ' answer= ' answer;
   end;
enddata;
run;
```

This is a partial listing of lines that are written to the SAS log:

```
s=  abcijk     x=  1   y=  101.5   c=  uvwxyzijk   answer=  102.5
s=  abcijk     x=  2   y=  104     c=  uvwxyzijk   answer=  106
s=  abcijk     x=  3   y=  106.5   c=  uvwxyzijk   answer=  109.5
s=  abcijk     x=  4   y=  109     c=  uvwxyzijk   answer=  113
s=  abcijk     x=  5   y=  111.5   c=  uvwxyzijk   answer=  116.5
```

TERM Method

Calls a DS2 system method where program finalizations can take place.

Syntax

METHOD TERM ( );

END;

Without Arguments

The METHOD TERM statement has no arguments. If you try to pass arguments, an error occurs.

Details

Typically, the TERM method contains any finalization code such as writing data to the SAS log. Code in the TERM method runs once at the end of the DS2 program.

Every DS2 program contains, either implicitly or explicitly, the INIT, RUN, and TERM methods. If you do not specify a METHOD TERM statement, DS2 automatically provides one.

For more information about the TERM method and how DS2 programs work, see "Methods" in *SAS DS2 Programmer's Guide*.

DS2 System Options

Overview of System Options

System options are instructions that affect the processing of an entire SAS program or interactive SAS session from the time the option is specified until it is changed.

Here is the syntax for specifying system options in an OPTIONS statement:

OPTIONS *options(s)*;

Here is an explanation of the syntax:

option
specifies one or more DS2system options that you want to change.

The following example shows how to use the system option DS2SCOND in an OPTIONS statement.

```
options ds2scond=none;
```

Note: DS2 does not support most SAS system options.

Dictionary

DS2SCOND= System Option

Specifies the level of messages that PROC DS2 displays in the SAS log for the DS2 variable declaration strict mode, which requires that every variable must be declared in the DS2 program.

Valid in: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window

PROC OPTIONS GROUP= ErrorHandling

Note: This option can be restricted by a site administrator. For more information, see "Restricted Options" in *SAS System Options: Reference*.

Syntax

DS2SCOND=ERROR | NONE | NOTE | WARNING

Required Arguments

ERROR
writes error messages to the SAS log.

Alias ERR

NONE
no messages are written to the SAS log.

NOTE
writes notes to the SAS log.

WARNING
writes warning messages to the SAS log. This is the default.

Alias WARN

Details

You can override the DS2SCOND system option by specifying the SCOND= option in the PROC DS2 statement.

DS2 Table Options

Overview of Table Options

Table options are analogous to data set options in DATA step programming.

Table options specify actions that apply only to the tables with which they appear. These are some of the operations that table options enable you to perform:

- rename variables
- specify passwords
- specify options for bulk loading data
- drop variables from processing or from the result table

Note: Some table options apply to all data sources. Others are data source specific. Table options that are not recognized by DS2 are passed without error to the underlying table driver.

Using Table Options in DS2

Table options can be used on these DS2 statements:

- DECLARE PACKAGE

- DECLARE THREAD
- DROP PACKAGE
- DROP THREAD
- PACKAGE
- SET
- DATA
- THREAD

Some table options can apply to packages and threads.

Most table options can apply to either input or output tables. If a table option is associated with an input table, the action applies to the table that is being read. If the option appears in the DATA statement, SAS applies the action to the output table. In DS2, table options for output tables must appear in the DATA statement, not in any OUTPUT statements that might be present.

Some table options, such as COMPRESS=, are meaningful only when you create a SAS data set because they set attributes that exist for the duration of the data set. To change or cancel most table options, you must re-create the table.

When table options appear in both input and output tables in the same DS2 program, first SAS applies table options to input tables. Then SAS evaluates programming statements or applies table options to output tables. Likewise, table options that are specified for the table being created are applied after programming statements are processed. For example, when using the RENAME= table option, the new names are not associated with the columns until the DS2 program is compiled.

In some instances, table options conflict when they are used in the same statement. For example, you cannot specify both the DROP= and KEEP= table options for the same variable in the same statement. Timing can also be an issue in some cases. For example, if you are using KEEP= and RENAME= in a table that is specified in the SET statement, KEEP= must use the original column names. SAS processes KEEP= before the table is read. The new names that are specified in RENAME= apply to the programming statements that follow the SET statement.

Table options are applicable whenever you are reading or writing a table that contains data. Therefore, table options work with DS2 packages and threads because packages and threads are stored in tables.

How to Specify Table Options in DS2

Table options are either enclosed in parentheses or preceded by a forward slash (/), depending on which statement they are used in. Table options should be placed at the end of the statement when they are preceded by the forward slash.

Table options are enclosed in parentheses when used in these statements:

- DECLARE PACKAGE

- DECLARE THREAD
- DROP PACKAGE
- DROP THREAD
- SET
- DATA

If the table option is enclosed in parentheses and the option value can be several items separated by spaces, the option values are also enclosed in parentheses. For examples, see "DS2 Table Option Examples" on page 1474.

Table options are preceded by a forward slash (/) when used in these statements:

- PACKAGE
- THREAD

DS2 Table Option Examples

Here are some examples of table options that are enclosed in parentheses:

```
data a (bufno=10);

data prod (drop=(price sales));

declare package sales (pw=lk34890f);

drop thread complex (write=24klj);
```

Here are some examples of table options that are preceded by a forward slash (/):

```
package invent /overwrite=yes;

thread work.t (double d, char (100) sp) /read=44kl7;
```

SAS Data Set Options That Are Not Valid in DS2

DS2 table options provide the same variable control functionality that is available through SAS data set options. However, the following SAS data set options are not valid in DS2:

CNTLLEV=	PWREQ=
DLDMGACTION=	REPEMPTY=

FILECLOSE=	REPLACE=
FIRSTOBS=	ROLE=
GENMAX=	SORTEDBY=
GENNUM=	SPILL=
INDEX=	TOBSNO=
MAXTABLEMEM=	USEDIRECTIO=
OBSBUF=	WHERE=
OBS=	WHEREUP=
OUTREP=	

In DS2, embedded FedSQL statements can be used to perform tasks such as specifying a WHERE clause or specifying a set of contiguous rows to process. For more information, see "SET Statement" on page 1430.

Note: Table options are also supported in FedSQL statements. Table options that are specified in a FedSQL statement must use FedSQL table option syntax.

DS2 Statement Table Options by Data Source

The following table lists the table options that are supported in DS2 programs by the data source that supports them. The options are listed alphabetically for each data source.

Table 13.1 *List of Supported Table Options by Data Source*

Data Source	Language Element	Category	Description
All	DROP= Table Option	Table control	For an input table, excludes the specified columns from processing; for an output table, excludes the specified columns from being written to the table.
	IN= Table Option	Table control	Creates an integer variable that indicates whether the table contributed data to the current row.
	INLINE Table Option	Table control	Specifies that the package or thread source code is not saved to a table for reuse and is validated and

Data Source	Language Element	Category	Description
			compiled only when loaded by a data program.
	KEEP= Table Option	Table control	For an input table, specifies the columns to process; for an output table, specifies the columns to write to the table.
	OVERWRITE= Table Option	Table control	For a table, drops the output table before the replacement output table is populated with rows; for packages and threads, drops the existing package or thread if a package or thread by the same name exists.
	RENAME= Table Option	Table control	Changes the name of a column.
Amazon Redshift	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
DB2	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
Google BigQuery	BULKLOAD= Table Option	Bulk loading	Determines whether SAS uses a DBMS facility to insert data into a DBMS table.
	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific options to be added to the DATA statement.
	FETCH_NUMERIC_TYPE= Table Option	Table control	Specifies how to handle NUMERIC data from Google BigQuery.
	READMODE= Table Option	Table access	Specifies the method to use when moving data from Google BigQuery into SAS.
	SCAN_COLUMN_STRINGS= Table Option	Table access	Specifies whether to determine the maximum length of character columns in a database table or a query.
Greenplum	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
	GP_DISTRIBUTED_BY= Table Option	Table control	Specifies the distribution key for the table being created.

Data Source	Language Element	Category	Description
Hive	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows database-specific options to be placed after the DATA statement.
	POST_TABLE_OPTS= Table Option	Table control	Allows database-specific options to be placed after the table name in a DATA statement.
	PRE_TABLE_OPTS= Table Option	Table control	Allows database-specific options to be placed before the table name in a DATA statement.
MDS	BULKLOAD= Table Option	Bulk loading	Determines whether SAS uses a DBMS facility to insert data into a DBMS table.
Microsoft SQL Server	BULKLOAD= Table Option	Bulk loading	Determines whether SAS uses a DBMS facility to insert data into a DBMS table.
	DBCREATE_INDEX_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the CREATE INDEX statement.
	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
MySQL	BULKLOAD= Table Option	Bulk loading	Determines whether SAS uses a DBMS facility to insert data into a DBMS table.
	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
Netezza	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows additional DBMS-specific syntax to be added to the DATA statement.
ODBC	DBCREATE_INDEX_OPTS= Table Option	Index control	Allows DBMS-specific syntax to be added to the CREATE INDEX statement.
	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
Oracle	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.

Data Source	Language Element	Category	Description
	ORHINTS= Table Option	Data control	Specifies Oracle hints to pass to Oracle from FedSQL.
	ORNUMERIC= Table Option	Table control	Specifies how numbers read from or inserted into the Oracle NUMBER column are treated.
PostgreSQL	BULKLOAD= Table Option	Bulk loading	Determines whether SAS uses a DBMS facility to insert data into a DBMS table.
SAP HANA	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
	TABLE_TYPE= Table Option	Table access	Specifies the type of table storage FedSQL uses when creating tables in SAP HANA.
SAS data set	ALTER= Table Option	Table control	Assigns an ALTER password to a SAS data set that prevents users from replacing or deleting the file, and enables access to a read- or write-protected file.
	BUFNO= Table Option	Table control	Specifies the number of buffers to be allocated for processing a SAS data set.
	BUFSIZE= Table Option	Table control	Specifies the size of a permanent buffer page for an output SAS data set.
	COMPRESS= Table Option	Table control	Specifies how rows are compressed in a new output data set.
	ENCRYPT= Table Option	Table control	Specifies whether to encrypt an output SAS data set.
	ENCRYPTKEY= Table Option	Table control	Specifies a key value for AES encryption.
	EXTENDOBSCOUNTER= Table Option	Table control	Specifies whether to extend the maximum observation count in a new output SAS data file.
	IDXNAME= Table Option	User control of index usage	Directs SAS to use a specific index to match the conditions of a WHERE clause.

Data Source	Language Element	Category	Description
	IDXWHERE= Table Option	User control of index usage	Specifies whether SAS uses an index search or a sequential search to match the conditions of a WHERE clause.
	LABEL= Table Option	Observation control	Specifies a label for a SAS data set.
	LOCKTABLE= Table Option	Table control	Places shared or exclusive locks on tables.
	POINTOBS= Table Option	Table control	Specifies whether SAS creates compressed data sets whose observations can be randomly accessed or sequentially accessed.
	PW= Table Option	Table control	Assigns a READ, WRITE, and ALTER password to a SAS file, and enables access to a password-protected file.
	READ= Table Option	Table control	Assigns a READ password to a SAS file that prevents users from reading the file, unless they enter the password.
	REUSE= Table Option	Table control	Specifies whether new rows can be written to free space in a compressed SAS data set.
	TYPE= Table Option	Table control	Specifies the data set type for a specially structured SAS data set.
	WRITE= Table Option	Table control	Assigns a WRITE password to a SAS file that prevents users from writing to the file or that enables access to a write-protected file.
SingleStore	BULKLOAD= Table Option	Bulk loading	Determines whether SAS uses a DBMS facility to insert data into a DBMS table.
	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.
SPD Engine data set	ALTER= Table Option	Table control	Assigns an ALTER password to an SPD Engine data set that prevents users from replacing or deleting the

Data Source	Language Element	Category	Description
			file, and enables access to a read- or write-protected file.
	ASYNCINDEX= Table Option	User control of index usage	Specifies to create indexes in parallel when creating multiple indexes on an SPD Engine data set.
	COMPRESS= Table Option	Table control	Specifies to compress SPD Engine data sets on disk as they are being created.
	ENCRYPT= Table Option	Table control	Specifies whether to encrypt an output SPD Engine data set.
	ENCRYPTKEY= Table Option	Table control	Specifies a key value for AES encryption.
	ENDOBS= Table Option	Observation control	Specifies the end observation number in a user-defined range of observations to be processed.
	IDXWHERE= Table Option	User control of index usage	Specifies to use indexes when processing WHERE expressions in the SPD Engine.
	IOBLOCKSIZE= Table Option	Table control	Specifies the size in bytes of a block of observations to be used in an I/O operation.
	LABEL= Table Option	Observation control	Specifies a label for an SPD Engine data set.
	PADCOMPRESS= Table Option	Table control	Specifies the number of bytes to add to compressed blocks in a data set opened for OUTPUT or UPDATE.
	PARTSIZE= Table Option	Table control	Specifies the size of the data component partitions in an SPD Engine data set.
	PW= Table Option	Table control	Assigns a READ, WRITE, and ALTER password to a SAS file, and enables access to a password-protected file.
	READ= Table Option	Table control	Assigns a READ password to a SAS file that prevents users from reading

Data Source	Language Element	Category	Description
			the file, unless they enter the password.
	STARTOBS= Table Option	Observation control	Specifies the starting observation number in a user-defined range of observations to be processed.
	THREADNUM= Table Option	Table control	Specifies the maximum number of I/O threads the SPD Engine can spawn for processing an SPD Engine data set.
	TYPE= Table Option	Table control	Specifies the data set type for a specially structured SPD Engine data set.
	UNIQUESAVE= Table Option	User control of index usage	Specifies to save observations with nonunique key values (the rejected observations) to a separate data set when appending or inserting observations to data sets with unique indexes.
	WHERENOINDEX= Table Option	User control of index usage	Specifies a list of indexes to exclude when making WHERE expression evaluations.
	WRITE= Table Option	Table control	Assigns a WRITE password to a SAS file that prevents users from writing to the file or that enables access to a write-protected file.
SPD Server table	COMPRESS= Table Option	Table control	Specifies to compress SPD Server tables on disk as they are being created.
	ENCRYPT= Table Option	Table access	Specifies whether to encrypt an output SPD Server table.
	ENCRYPTKEY= Table Option	Table access	Specifies a key for AES encryption.
	ENDOBS= Table Option	Observation control	Specifies the end observation number in a user-defined range of observations to be processed.
	IOBLOCKSIZE= Table Option	Table control	Specifies the size in bytes of a block of rows to be used in an I/O operation.

Data Source	Language Element	Category	Description
	PARTSIZE= Table Option	Table control	Specifies the size of the data component partitions in an SPD Server table.
	PW= Table Option	Table access	Enables you to access an SPD Server table that is protected by SAS Proprietary encryption.
	STARTOBS= Table Option	Observation control	Specifies the starting observation number in a user-defined range of observations to be processed.
Spark	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows database-specific options to be placed after the DATA statement.
	POST_TABLE_OPTS= Table Option	Table control	Allows database-specific options to be placed after the table name in a DATA statement.
	PRE_TABLE_OPTS= Table Option	Table control	Allows database-specific options to be placed before the table name in a DATA statement.
Teradata	DBCREATE_TABLE_OPTS= Table Option	Table control	Allows DBMS-specific syntax to be added to the DATA statement.

Dictionary

ALTER= Table Option

Assigns an ALTER password to a data set that prevents users from replacing or deleting the file, and enables access to a Read- and Write-protected file.

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set

Note: Check your log after this operation to ensure that the password values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in “Blotting Out Password and Encryption Key Values from the Log” in *SAS Programmer’s Guide: Essentials*.

Syntax

ALTER==*alter-password*

Required Argument

alter-password
must be a valid SAS name.

Details

The ALTER= option applies only to a SAS data set. You can use this option to assign a password or to access a read-protected, write-protected, or alter-protected file. When you replace a data set that is protected with an ALTER password, the new data set inherits the ALTER password.

The password is blotted out when the code is written in the SAS log. Here is an example:

```
set a(alter=XXXXXXX);
```

Note: A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

ASYNCINDEX= Table Option

Specifies to create indexes in parallel when creating multiple indexes on an SPD Engine data set.

Valid in:	CREATE INDEX Statement
Category:	User Control of Index Usage
Restriction:	This table option is not supported on the CAS server.
Data source:	SPD Engine data set

Syntax

ASYNCINDEX= YES | NO

Arguments

YES
creates the indexes in parallel (asynchronously).

NO
creates one index at a time (synchronously). This is the default value.

Details

The SPD Engine can create multiple indexes for a data set at the same time. The SPD Engine spawns a single thread for each index created, and then processes the threads simultaneously. Although creating indexes in parallel is much faster than creating one index at a time, the default for this option is NO. Parallel creation requires additional utility work space and additional memory, which might not be available. If the index creation fails due to insufficient resources, you can do one of the following:

- set the SAS system option to MEMSIZE=0
- increase the size of the utility file space using the SPDEUTILLOC= system option

You increase the memory space that is used for index sorting using the SPDEINDEXSORTSIZE= system option. If you specify to create indexes in parallel, specify a large-enough space using the SPDEUTILLOC= system option.

BL_DELETE_DATAFILE= Table Option

Specifies whether to delete intermediate files created by the bulk loading facility.

Category: Bulk Loading

Default: YES

Restriction: This table option is not supported on the CAS server.

Requirement: To specify this option, you must also set BULKLOAD=YES or BULKUNLOAD=YES.

Data source: Snowflake

Syntax

BL_DELETE_DATAFILE= YES | NO

Arguments

YES
deletes all (data, control, and log) files that the SAS/ACCESS engine creates for the DBMS bulk-load facility.

NO
retains the files.

Details

This option must be specified within the "BULKOPTS= Table Option" in *SAS FedSQL Language Reference*

See Also

Table Options:

- "BULKLOAD= Table Option" on page 1487

BUFNO= Table Option

Specifies the number of buffers to be allocated for processing a SAS data set.

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set

Syntax

BUFNO= *n* | *n*K | *hex*X | MIN | MAX

Arguments

***n* | *n*K**
specifies the number of buffers in multiples of 1 (bytes); 1,024 (kilobytes). For example, a value of `8` specifies 8 buffers, and a value of `1K` specifies 1024 buffers.

Requirement *K* must be uppercased.

***hex*X**
specifies the number of buffers as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by an X. For example, the value `2dX` sets the number of buffers to 45 buffers.

Requirement *X* must be uppercased.

MIN
sets the minimum number of buffers to 0, which causes SAS to use the minimum optimal value for the operating environment. This is the default value.

MAX
sets the number of buffers to the maximum possible number in your operating environment, up to the largest four-byte, signed integer. The largest four-byte, signed integer is 2^{31}–1, or approximately 2 billion.

Details

The buffer number is not a permanent attribute of the data set; it is valid only for the current operation.

The BUFNO= table option applies to SAS data sets that are opened for input, output, or update.

A larger number of buffers can speed up execution time by limiting the number of input and output (I/O) operations that are required for a particular SAS data set. However, the improvement in execution time comes at the expense of increased memory consumption.

To reduce I/O operations on a small data set as well as speed execution time, allocate one buffer for each page of data to be processed. This technique is most effective if you read the same observations several times during processing.

BUFSIZE= Table Option

Specifies the size of a permanent buffer page for an output SAS data set.

Category: Table Control

Restrictions: This table option is not supported on the CAS server.
Use with output data sets only.

Data source: SAS data set

Syntax

BUFSIZE=*n* | *n*K | *n*M | *n*G | *hex*X | MIN | MAX

Arguments

***n* | *n*K | *n*M | *n*G**
specifies the page size in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). For example, a value of `8` specifies a page size of 8 bytes, and a value of `4k` specifies a page size of 4096 bytes.

Requirement *K*, *M*, and *G* must be uppercased.

***hex*X**
specifies the page size as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by an X. For example, the value `2dx` sets the page size to 45 bytes.

Requirement *X* must be uppercased.

MIN
sets the minimum number of buffers to 0, which causes SAS to use the minimum optimal value for the operating environment.

MAX
sets the page size to the maximum possible number in your operating environment, up to the largest four-byte, signed integer. The largest four-byte, signed integer is 2^{31}–1, or approximately 2 billion bytes.

Details

The page size is the amount of data that can be transferred for a single I/O operation to one buffer. The page size is a permanent attribute of the data set and is used when the data set is processed.

A larger page size can speed up execution time by reducing the number of times SAS has to read from or write to the storage medium. However, the improvement in execution time comes at the cost of increased memory consumption.

To change the page size, copy the data set and either specify a new page or use the SAS default. To reset the page size to the default value in your operating environment, specify BUFSIZE=0.

Operating Environment Information: The default value for the BUFSIZE= table option is determined by your operating environment and is set to optimize sequential access. To improve performance for direct (random) access, you should change the value for BUFSIZE=.

BULKLOAD= Table Option

Determines whether SAS uses a DBMS facility to insert data into a DBMS table.

Category:	Bulk Loading
Default:	NO
Restriction:	This table option is not supported on the CAS server.
Requirement:	Appropriate SAS/ACCESS software for the target data source must be configured.
Data source:	MDS, Microsoft SQL Server, MySQL, PostgreSQL, SingleStore
Notes:	Support for bulk loading in Amazon Redshift and Microsoft SQL Server starts in 2024.07.

Support for bulk loading in MySQL and SingleStore starts in 2024.10.

Support for bulk loading in PostgreSQL starts in 2024.12.

Tip: DS2 bulk loading to third-party DBMS is available for FedSQL statements that are submitted in the DS2 SQLSTMT package. For more information, see "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*.

See: Understanding Bulk Load Table Options

Syntax

BULKLOAD= YES | NO

Arguments

YES
calls a DBMS-specific bulk-load facility in order to insert or append rows to a DBMS table.

NO
does not call the DBMS-specific bulk-load facility.

Details

Overview

Bulk loading is the fastest way to insert rows into a DBMS table. To enable bulk loading for SAS/ACCESS connections, specify BULKLOAD=YES.

Some SAS/ACCESS engines enable bulk loading for PROC DS2 when BULKLOAD=YES is specified in the LIBNAME statement. These engines pass an internal connection option in the connection string that they generate for the procedure. For these data sources, the BULKLOAD= table option can be used to override the setting in the LIBNAME statement.

For other data sources, the BULKLOAD= table option is the way to enable bulk loading. For most of these data sources, bulk loading is enabled simply by setting the BULKLOAD= table option to YES.

When BULKLOAD=NO, a simple multi-row insert SQL scheme is used to insert data rows.

Usage Notes

Microsoft SQL Server

The table option BULKLOAD=YES enables bulk loading for the SQL Server database. This option sets the attribute SQL_ATTR_BULK_LOAD_ENABLED=1 in the underlying DataDirect driver. There are no data source-specific table options for bulk loading to Microsoft SQL Server.

MDS

The table option BULKLOAD=YES enables bulk loading for MDS. When the BULKLOAD= table option is set to YES, newly inserted rows are committed immediately and become visible to existing transactions. When the BULKLOAD= table option is set to NO or not set, newly inserted rows are not visible until the existing transactions are committed or rolled back. There are no data source-specific table options for bulk loading to MDS.

MySQL

Bulk loading can be enabled in the LIBNAME statement for the MYSQL engine or by specifying YES in the BULKLOAD= table option. There are no data source-specific table options for bulk loading to MySQL.

Intermediate files for bulk loading are created in the location specified in the UTILLOC= system option.

PostgreSQL

Bulk loading can be enabled in the LIBNAME statement for the POSTGRES engine or by specifying YES in the BULKLOAD= table option. There are no data source-specific table options that are required to enable bulk loading in PostgreSQL.

SingleStore

Bulk loading can be enabled in the LIBNAME statement for the SSTORE engine or by specifying YES in the BULKLOAD= table option. There are no data source-specific table options for bulk loading to SingleStore.

Intermediate files for bulk loading are created in the location specified in the UTILLOC= system option.

Example:

```
data accesslib.myexample (BULKLOAD=YES);
   dcl float         f;
   method init();
      f=11.01;
      output;
   end;
enddata;
run;
```

Table Options:

- "BULKOPTS= Table Option" in *SAS FedSQL Language Reference*

COMPRESS= Table Option

Specifies how rows are compressed in a new output data set or table.

Category: Table Control

Restrictions: This table option is not supported on the CAS server.
Use with output tables only.

Data source: SAS data set, SPD Engine data set, SPD Server table

Syntax

COMPRESS= NO | YES | CHAR | BINARY

Arguments

CHAR | YES
specifies that the rows in a newly created table are compressed (variable length records). SAS data sets are compressed. by using Run Length Encoding (RLE). RLE compresses rows by reducing repeated consecutive characters (including blanks) to two-byte or three-byte representations. SPD Engine data sets are compressed by using the run length compression algorithm SPDSRLC2. SPD Server tables are compressed by using the run-length compression algorithm SPDSRLLC.

Alias ON (SPD Engine data set only)

Tip Use this compression algorithm for character data.

BINARY
specifies that the rows in a newly created data set or table are compressed by SAS using Ross Data Compression (RDC). RDC combines run-length encoding and sliding-window compression to compress the file. SPD Engine data sets are compressed by the SPD Engine by using SPDSRDC.

Tip This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (numeric variables). Because the compression function operates on a single record at a time, the record length needs to be several hundred bytes or larger for effective compression.

NO
specifies that the rows in a newly created table are uncompressed (fixed-length records).

Details

Compressing a table is a process that reduces the number of bytes required to represent each row. Advantages of compressing a table include reduced storage requirements for the table and fewer I/O operations necessary to read or write to the data during processing. However, more CPU resources are required to read a compressed table (because of the overhead of uncompressing each row). Also, there are situations where the resulting file size might increase rather than decrease.

Use the COMPRESS= table option to compress an individual table. Specify the option for an output table only—that is, a table name on the CREATE TABLE statement.

Note: In SPD Engine data sets and SPD Server tables, encryption and compression are mutually exclusive. You cannot specify encryption for a compressed SPD Engine data set or SPD Server table. You cannot compress an encrypted SPD Engine data set or SPD Server table.

After a table is compressed, the setting is a permanent attribute of the table, which means that to change the setting, you must re-create the table. That is, to uncompress a table, you must drop the table by using the DROP TABLE statement and re-create the table with the CREATE TABLE statement and the COMPRESS=NO option.

When you specify COMPRESS= to compress an SPD Engine data set or SPD Server table, the table drivers compress, by blocks, the table as it is created. To specify the size of the compressed blocks, use the "IOBLOCKSIZE= Table Option" on page 1514.

The SPD Engine table driver also supports the PADCOMPRESS= table option when creating or updating the SPD Engine data set. The PADCOMPRESS= option enables you to add padding to the newly compressed blocks. See the "PADCOMPRESS= Table Option" on page 1523.

Comparisons

The COMPRESS= table option overrides the COMPRESS= connection string option.

SAS data sets only: When you create a compressed table, you can also specify the REUSE=YES table option in order to track and reuse space. With REUSE=YES, new rows are inserted in space freed when other rows are updated or deleted. When the default REUSE=NO is in effect, new rows are appended to the existing table.

DBCREATE_INDEX_OPTS= Table Option

Allows DBMS-specific options to be added to the CREATE INDEX statement.

Category: Index Control

Restriction: This table option is not supported on the CAS server.

Data source: Microsoft SQL Server, ODBC

Syntax

DBCREATE_INDEX_OPTS= '*DBMS-SQL-clauses*'

Arguments

DBMS-SQL-clauses
specifies one or more DBMS-specific clauses that can be appended to the end of an SQL CREATE INDEX statement.

Details

This option enables you to add DBMS-specific clauses to the end of the CREATE INDEX statement. The interface passes the CREATE INDEX statement and its clauses to the DBMS, which executes the statement and creates the DBMS index.

Example

In the following example, a Hive index is created with the value of the DBCREATE_INDEX_OPTS= "as 'compact' with deferred rebuild" option appended to the CREATE INDEX statement:

```
create index "COL1_1A03" on "TKTS002_1A03"{options DBCREATE_INDEX_OPTS="as 'compact'
with deferred rebuild"}("COL1")
```

The following CREATE INDEX statement is passed to the DBMS in order to create the index:

```
create index 'COL1_1A03' on table 'TKTS002_1A03'('COL1') as 'compact' with
```

```
deferred rebuild
```

DBCREATE_TABLE_OPTS= Table Option

Specifies DBMS-specific options to be added to the DATA statement.

Restriction: This table option is not supported on the CAS server.

Data source: Amazon Redshift, DB2 under UNIX and PC, Google BigQuery, Greenplum, Hive, Microsoft SQL Server, MySQL, Netezza, Oracle, SAP HANA, Spark, Teradata

Syntax

DBCREATE_TABLE_OPTS= '*DBMS-options*'

Required Argument

DBMS-options
specifies one or more valid DBMS-specific options. If more than one option is specified, the options should be separated in the same way as options are separated in the DBMS.

Details

Basics

This option enables you to add DBMS-specific options to the DATA statement. The interface passes the DATA statement and its clauses to the DBMS, which executes the statement and creates the DBMS table. An example of this would be to use the COLUMN-DELIMITER= option to specify a column delimiter for Hadoop files.

Note: If the SAS/ACCESS DBCREATE_TABLE_OPTS LIBNAME option and the DS2 DBCREATE_TABLE_OPTS table option are used, the DS2 table option setting takes precedence.

Quoting DBMS Options

The *DBMS-options* must be enclosed with single-quotation marks. Elements within *DBMS-options* that are quoted should use double the quotation marks around the element. For example, if single quotation marks are used, you use two single quotation marks. If double quotation marks are used, you use two sets of double quotation marks. Here are some examples:

```
/* Using double quotes around DBMS-option element causes an error */
DBCREATE_TABLE_OPTS="FIELDS TERMINATED BY '\012' "
```

```
/* Using single quotes around DBMS-option element works */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY "\012" '

/* You can double the quote character to insert one into a quoted value*/

/* doubled single quote passes single quote to database */
/* trailing space after last set of single quotes added for emphasis */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY ''\012'' '

/* doubled double quotes passes double quotes to database */
/* trailing space after last set of double quotes added for emphasis */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY ""\012"" '
```

Note: If your program is run in Spark, do not use two single or double quotation marks within the *DBMS-options* value. When Spark creates the output table, it does not remove one of the sets of quotation marks. Here is an example:

```
/* This value with doubled single quotes */
DBCREATE_TABLE_OPTS='FIELDS TERMINATED BY ''\012'' '
/* gets translated to this for any data source except Spark */
FIELDS TERMINATED BY '\012'
/* and gets translated like this for Spark jobs which causes an error */
FIELDS TERMINATED BY ''\012''
```

Examples

Example 1

In the following example, the Teradata table Teralib is created with the value of the `primary index ()` option appended to the DATA statement.

```
libname teralib teradata server=terasvr database=model user=myid password=xxxx;

proc delete data=teralib.outtable;
proc ds2;
data teralib.outtable(overwrite=yes dbcreate_table_opts='primary index(i)');
   retain x 0;
   method run();
      do i=1 to 10 by 1 ;
         x=i;
         output;
      end;
   end;
enddata;
run;
quit;
```

Example 2

In the following example, the Hive table **Hivelib.Dzoutput** is created and the `partition by` option is appended to the DATA statement. In this example, **Col1** exists in the table in the SET statement, **Hivelib.Dzpt**, although this is not required.

```
options set=SAS_HADOOP_JAR_PATH="jar-path";
options set=SAS_HADOOP_CONFIG_PATH="config-path";
libname hivelib hadoop server="hostname" user=username password=xxxx
schema=ds2ip
dbmax_text=300;

proc ds2;
data hivelib.dzoutput (dbcreate_table_opts="partitioned by (col1 int)"
overwrite=yes);
   method run();
       set hivelib.dzpt;
          x+1;
          output; output;
   end;
enddata;
run;
quit;
```

Example 3

When you create a DB2 table, IBM Integrated Analytics System (IIAS) does not allow opening an updateable cursor on an ORGANIZED BY COLUMN table. The workaround is set the option DBCREATE_TABLE_OPTS="organize by row" when you create the table as follows:

```
data test (DBCREATE_TABLE_OPTS="organize by row");
     dcl int x;
```

DROP= Table Option

For an input table, excludes the specified columns from processing; for an output table, excludes the specified columns from being written to the table.

Data source: All

Syntax

DROP= (*column-list*)

Required Argument

column-list
specifies the names of the columns to omit from the output table.

Restriction Numbered range lists in the format *col1–col5* and name prefix lists in the format *col:* are not supported.

Details

The DROP= table option specifies that all columns in the *column-list* should not be included in the creation of output rows. Normally, all columns in the program data vector are included in the output rows. If the drop attribute is specified, all columns not included in the drop statement are used to create columns in the output rows.

If the DROP= table option is associated with an input table, the columns are not available for processing during program execution.

Comparisons

The DROP= table option differs from the DROP statement in these ways:

- In DS2 programs, the DROP= table option can apply to both input and output tables. The DROP statement applies only to output tables.
- In DS2 programs, when you create multiple output tables, use the DROP= table option to write different columns to different tables. The DROP statement applies to all output tables.
- The KEEP= table option specifies a list of columns to be included in processing or to be written to the output table.

Examples

Example 1: Excluding Columns from Output Tables

In this example, the variables SALARY and GENDER are not included in processing and they are not written to either output tables.

```
data plan1 plan2;
   method run ();
      set payroll(drop=(salary gender));
      if hired<'01jan07'd then output plan1;
         else output plan2;
   end;
enddata;
```

You cannot use SALARY or GENDER in any logic in the DS2 program because DROP= prevents the SET statement from reading them from PAYROLL.

Example 2: Processing Columns without Writing Them to the Output Table

In this example, SALARY and GENDER are not written to PLAN2, but they are written to PLAN1.

```
data plan1 plan2(drop=(salary gender));
   method run ();
       set payroll;
       if hired<'01jan07'd then output plan1;
          else output plan2;
   end;
enddata;
```

Statements:

- "DROP Statement" on page 1359

Table Options:

- "KEEP= Table Option" on page 1515

ENCRYPT= Table Option

Specifies whether to encrypt an output SAS data set.

Restrictions: Use with output data sets only.
This table option is not supported on the CAS server.
In SPD Engine data sets, this table option cannot be used with COMPRESS=.

Data source: SAS data set, SPD Engine data set, SPD Server table

Syntax

ENCRYPT==AES | AES2 | NO | YES

Required Arguments

AES | AES2 | NO | YES
specifies whether to encrypt an output SAS data set.

AES or AES2
encrypts the file using the AES (Advanced Encryption Standard) algorithm. AES provides enhanced encryption. AES2 specifies to use a stronger key generation algorithm. You must specify the ENCRYPTKEY= table option when you are

using ENCRYPT=AES or ENCRYPT=AES2. For more information, see "ENCRYPTKEY= Table Option" on page 1500.

Restriction SPD Engine and SPD Server do not support AES2 encryption.

CAUTION **Record all ENCRYPTKEY= values when you are using ENCRYPT=AES or ENCRYPT=AES2.** If you forget to record the ENCRYPTKEY= value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= value. The following note is written to the log:

```
Note: If you lose or forget the ENCRYPTKEY= value, there will
be no way to open the file or recover the data.
```

NO
does not encrypt the data set.

YES
encrypts the data set using the SAS Proprietary algorithm. This encryption uses passwords that are stored in the data set. You must specify the READ= table option or the PW= table option at the same time that you specify ENCRYPT=YES. For more information, see "READ= Table Option" on page 1530 and "PW= Table Option" on page 1529.

Interaction Because the encryption method uses passwords, you cannot change *any* password on an encrypted file without re-creating the table.

CAUTION **Record all passwords when you are using ENCRYPT=YES.** If you forget the passwords, you cannot reset them without assistance from SAS. This is a time-consuming and resource-intensive process.

Details

When you use ENCRYPT=YES, the following rules apply:

- If the data file is encrypted, all associated indexes are also encrypted, except for SPD Server tables. SPD Server does not encrypt table indexes or metadata. Only table row data are encrypted.
- In order to copy an encrypted data file, the output engine must support encryption. Otherwise, the data file is not copied.
- Encryption requires approximately the same amount of CPU resources as compression.
- You cannot use PROC CPORT on SAS Proprietary encrypted SAS files.

When you use ENCRYPT=AES or ENCRYPT=AES2, the following rules apply:

- You must use the ENCRYPTKEY= table option when encrypting a table.
- You must use the ENCRYPTKEY= table option to enable decryption.
- A SAS data set encrypted with AES encryption can be decrypted only by engines that support AES encryption.

- You cannot change the ENCRYPTKEY= value in an AES encrypted data file without re-creating the data file.
- Data files with referential integrity constraints can use AES encryption. All primary key and foreign key data files must use the same encryption key that opens all referencing foreign key and primary key data files.

If a SAS data set with AES2 encryption is copied to create a new SPD Engine data set or SPD Server table, the encryption converts to AES. A warning is written to the log.

Note: You can create an encrypted DS2 package or thread program by using the ENCRYPT argument in the PACKAGE and THREAD statements.

For more information about the encryption provided by SAS, see *SAS Viya Platform Encryption: Data in Motion*.

Example

This example creates an encrypted SAS data set:

```
proc ds2;
  data myfiles.mytable (encrypt=yes pw=mine);
      declare double j j2;
      method run();
         do j = 1 to 1000;
            j2 = 2*j;
            output;
         end;
      end;
  enddata;
 run;
quit;
```

This example reads the encrypted SAS data set:

```
proc print data=myfiles.mytable (pw=mine obs=10);
run;
```

Table Options:

- “ENCRYPTKEY= Table Option” on page 1500

ENCRYPTKEY= Table Option

Specifies a key value for AES encryption.

Restrictions: Use only with AES and AES2 encrypted data files.
This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set, SPD Server table

Note: Check your log after this operation to ensure that the encrypt key values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in *SAS Language Reference: Concepts*.

Syntax

ENCRYPTKEY=*key-value*

Required Argument

key-value
assigns an encrypt key value. You must specify the ENCRYPTKEY= table option when you are using ENCRYPT=AES or ENCRYPT=AES2. The key value can be up to 64-bytes long.

Requirement The ENCRYPTKEY= key value can be created with or without quotation marks. For more information, see “Rules for Using Quotation Marks When Creating the ENCRYPTKEY Value” on page 1501.

Note When the ENCRYPTKEY= key value uses DBCS characters, the 64-byte limit applies to the character string after it has been transcoded to UTF-8 encoding. You can use the following DATA step to calculate the length in bytes of a key value in DBCS:

```
data _null_;
    key=length(unicodec('key-value','UTF8'));
    put 'key length=' key;
run;
```

Details

The Basics

CAUTION

Record the key value. If you forget the ENCRYPTKEY= key value, you lose your data. SAS cannot assist you in recovering the ENCRYPTKEY= key value because the key value is not stored with the data set. The following warning is written to the log:

```
WARNING: If you lose or forget the ENCRYPTKEY= value, there
will be not be any way to open the file or recover the data.
```

The ENCRYPTKEY= option prevents access to the contents of the file only. The ENCRYPTKEY= table option does not protect the table from deletion or replacement. Encrypted data sets can be deleted by using any of the following scenarios without having to specify an ENCRYPTKEY= key value:

- the KILL option in PROC DATASETS
- the DROP statement in PROC SQL
- the DELETE statement in PROC DATASETS or the DELETE procedure

To protect the file from deletion or replacement, the file must also contain an ALTER= password.

You cannot change the ENCRYPTKEY= value in an AES encrypted data file. To change the encryption key value, you must re-create the data set. The OVERWRITE= table option cannot be used to re-create a data set that is encrypted with an encryption key. PROC FEDSQL cannot be used to delete the table. Use PROC DELETE or the PROC SQL DROP TABLE statement to delete the data set before re-creating the data set with DS2.

It is possible to use a macro variable as the ENCRYPTKEY= key value. When you specify a macro variable for the ENCRYPTKEY= key value, you must enclose the macro variable in double quotation marks. If you do not use the double quotation marks, unpredictable results can occur. The following example defines a macro variable and uses the macro variable as the ENCRYPTKEY= key value:

```
%let secret=myvalue;
data my.dsname(encrypt=aes encryptkey="&secret");
```

Note: When DS2 runs outside of SAS, such as in the SAS Federation Server and in grid computing environments, the SAS macro facility is not available and DS2 programs with macros fail to compile.

Rules for Using Quotation Marks When Creating the ENCRYPTKEY Value

When an encrypt key value is created without quotation marks, the value must start with a letter and can include alphanumeric characters and underscores only. The key value cannot have blank spaces. The letters can be uppercase, lowercase, or mixed case. Here is an example of what is allowed:

```
encryptkey=G_rEeN1
```

The evaluation of the key value is not case sensitive. The following key value can be used to read a data set created with the preceding key:

```
encryptkey=G_REEN1
```

An encrypt key value specified within single quotation marks can include alphanumeric, special, and DBCS characters. Blank spaces are allowed, but the key value cannot consist of all blanks. Evaluation of the string is case-sensitive. Here is an example of a valid key value. The exact same value that is used to encrypt the data set must be specified in order to be able to read the data set.

```
encryptkey='1Gr*#E7e.N 1'
```

An encrypt key value that is specified within double quotation marks has the same requirements as a key value that is specified within single-quotation marks. In addition, the encrypt key value is enabled for macro resolution.

Example

This example uses the ENCRYPT=AES option.

```
proc ds2;
data salary (encrypt=aes encryptkey='1Gr*#E7e.N 1');
   dcl char(8) name;
   dcl double yrsal;
   dcl double bonuspct;
   method init();
      name='Muriel'; yrsal=34567; bonuspct=3.2;
        name='Bjorn'; yrsal=74644; bonuspct=2.5;
      name='Freda'; yrsal=38755; bonuspct=4.1;
        name='Benny'; yrsal=29855; bonuspct=3.5;
        name='Agnetha'; yrsal=70998; bonuspct=4.1;
   end;
run;
quit;
```

To run the CONTENTS procedure, specify the encryption key value as follows:

```
proc contents data=salary (encryptkey='1Gr*#E7e.N 1');
run;
```

Table Options:

- “ENCRYPT= Table Option” on page 1497
- “Encryption” in *SAS Programmer’s Guide: Essentials*

ENDOBS= Table Option

Specifies the end observation number in a user-defined range of observations to be processed.

Valid in: SELECT statement

Category: Observation Control

Restrictions: This table option is not supported on the CAS server.
Use with input data sets only

Interaction: Use in conjunction with STARTOBS= table option

Data source: SPD Engine data set, SPD Server table

Syntax

ENDOBS= *n*

Arguments

n
is the number of the end observation.

Details

The software processes all of the observations in the entire data set unless you specify a range of observations with the STARTOBS= or ENDOBS= options. If the STARTOBS= option is used without the ENDOBS= option, the implied value of ENDOBS= is the end of the data set. When both options are used together, the value of ENDOBS= must be greater than the value of STARTOBS=.

In contrast to the SAS software options FIRSTOBS= and OBS=, the STARTOBS= and ENDOBS= SPD Server options can be used for WHERE clause processing in addition to table input operations. When ENDOBS= is used in a WHERE expression, the ENDOBS= value represents the last observation to process, rather than the number of observations to return.

Example

The following code shows how the ENDOBS= table option is specified in the FedSQL SELECT statement:

```
select * from spdslib.table1(startobs=3 endobs=4);
```

See Also

Table Options:

- "STARTOBS= Table Option" on page 1534

EXTENDOBSCOUNTER= Table Option

Specifies whether to extend the maximum observation count in a new output SAS data set.

Valid in: CREATE TABLE statement

Category: Table Control

Alias: EOC=

Default: YES

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set

Syntax

EXTENDOBSCOUNTER=YES | NO

Arguments

YES
requests an enhanced file format in a newly created SAS data set that counts observations beyond the 32-bit limitation. Although this SAS data set is created for an operating environment that stores the number of observations with a 32-bit integer, the data set behaves like a 64-bit file with respect to counters. This is the default value.

Restriction EXTENDOBSCOUNTER=YES is valid only for an output SAS data set whose internal data representation stores the observation count as a 32-bit integer. EXTENDOBSCOUNTER= is ignored for SAS data sets with a 64-bit integer.

NO
specifies that the maximum observation count in a newly created SAS data file is determined by the long integer size for the operating environment. In operating environments with a 32-bit integer, the maximum number is 2**31-1 or approximately two billion observations (2,147,483,647). In operating environments with a 64-bit integer, the maximum number is 2**63-1 or approximately 9.2 quintillion observations.

Details

Historically, SAS had a limitation in which up to approximately two billion observations could be counted and fully supported for operating environments with a 32-bit long integer. The EXTENDOBSCOUNTER= table option extends the limit to

match that of operating environments with a 64-bit long integer. EXTENDOBSCOUNTER=NO is provided for backward compatibility.

FETCH_NUMERIC_TYPE= Table Option

Specifies how to handle NUMERIC data from Google BigQuery.

Category: Table Control

Default: FLOAT64

Data source: Google BigQuery

Note: Support for this option starts in 2024.09.

Syntax

FETCH_NUMERIC_TYPE=FLOAT64 | NUMERIC

Required Arguments

FLOAT64
specifies that NUMERIC(p,s) and BIGNUMERIC (p,s) values that are retrieved from Google BigQuery are treated as DOUBLEs. (The DS2 DOUBLE data type is mapped to the Google BigQuery FLOAT64 data type.)

NUMERIC
specifies that NUMERIC(p,s) and BIGNUMERIC (p,s) values that are retrieved from Google BigQuery are treated as NUMERIC.

Details

The default value improves read performance. This table option enables you to revert to NUMERIC behavior.

Data definition is not affected.

GP_DISTRIBUTED_BY= Table Option

Specifies the distribution key for the table being created.

Category: Table Control

Alias: DISTRIBUTED_BY=

Restriction: This table option is not supported on the CAS server.

Data source: Greenplum

Syntax

GP_DISTRIBUTED_BY= 'DISTRIBUTED BY (*column*[, ...*column*])
| DISTRIBUTED RANDOMLY'

Arguments

DISTRIBUTED BY (*column*, [...*column*])
specifies one or more DBMS column names to use as the distribution key.

DISTRIBUTED RANDOMLY
specifies to determine the column or set of columns to use to distribute table rows across database segments. This is known as round-robin distribution.

Details

DISTRIBUTED BY uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you might choose DISTRIBUTED RANDOMLY, which sends the data round-robin to the segment instances. If a value is not supplied, then hash distribution is chosen using the primary key (if the table has one) or the first eligible column of the table as the distribution key.

DISTRIBUTED_BY can be submitted as shown above or within the DBCREATE_TABLE_OPTS= table option. Here is an example of how it is specified in DBCREATE_TABLE_OPTS=:

```
dbcreate_table_opts='distributed by ("b")'
```

See Also

Table Options:

- “DBCREATE_TABLE_OPTS= Table Option” on page 1493

IDXNAME= Table Option

Directs SAS to use a specific index to match the conditions of a WHERE clause.

Category: User Control of SAS Index Usage

Restrictions: This table option is not supported on the CAS server.

Use with input data sets only

Cannot be used with the IDXWHERE= table option

Data source: SAS data set

Syntax

IDXNAME= *index-name*

Arguments

index-name

specifies the name (up to 32 characters) of a simple or composite index for the SAS data set. SAS does not attempt to determine whether the specified index is the best one or whether a sequential search might be more resource efficient.

Interaction The specification is not a permanent attribute of the data set and is valid only for the current use of the data set.

Details

By default, to satisfy the conditions of a WHERE clause for an indexed SAS data set, SAS identifies zero or more candidate indexes that could be used to optimize the WHERE clause. From the list of candidate indexes, SAS selects the one that it determines will provide the best performance, or rejects all of the indexes if a sequential pass of the data is expected to be more efficient.

Because the index that SAS selects might not always provide the best optimization, you can direct SAS to use one of the candidate indexes by specifying the IDXNAME= table option. If you specify an index that SAS does not identify as a candidate index, then IDXNAME= table option does not process the request. That is, IDXNAME= does not allow you to specify an index that would produce incorrect results.

Comparisons

The IDXWHERE= table option enables you to override the SAS decision about whether to use an index.

Example

This example uses the IDXNAME= table option to direct SAS to use a specific index to optimize the WHERE clause. SAS then disregards the possibility that a sequential search of the data set might be more resource efficient and does not

attempt to determine whether the specified index is the best one. (Note that the EMPNUM index was not created with the NOMISS option.)

```
create table mydata.empnew
   as select * from mydata.employee {option idxname=empnum}
   where empnum < 2000;
```

See Also

Table options

- "IDXWHERE= Table Option" on page 1508

IDXWHERE= Table Option

Specifies whether SAS uses an index search or a sequential search to match the conditions of a WHERE clause.

Category: User Control of SAS Index Usage

Restrictions: This table option is not supported on the CAS server.
Use with input data sets only
SAS data sets: Cannot be used with IDXNAME=
SPD Engine data sets: IDXWHERE=NO cannot be used with WHERENOINDEX=

Data source: SAS data set, SPD Engine data set

Syntax

IDXWHERE= YES | NO

Arguments

YES
tells SAS to choose the best index to optimize a WHERE clause, and to disregard the possibility that a sequential search of the data set might be more resource-efficient. This is the default value.

NO
tells SAS to ignore all indexes and satisfy the conditions of a WHERE clause with a sequential search of the data set.

Notes You cannot use the IDXWHERE= table option to override the use of an index to process a BY statement.

You cannot use the WHERENOINDEX= table option when IDXWHERE=NO is used.

Details

By default, to satisfy the conditions of a WHERE clause for an indexed data set, the software decides whether to use an index or to read the data set sequentially. The software estimates the relative efficiency and chooses the method that is more efficient.

You might need to override the software's decision by specifying the IDXWHERE= table option because the decision is based on general rules that occasionally might not produce the best results. That is, by specifying the IDXWHERE= table option, you are able to determine the processing method.

Note: The specification is not a permanent attribute of the data set and is valid only for the current use of the data set.

Comparisons

The IDXNAME= table option (which is supported only for SAS data sets) enables you to direct SAS to use a specific index.

The WHERENOINDEX= table option enables you to specify a list of indexes to exclude when making WHERE expression evaluations.

Examples

Example 1: Specifying Index Usage

This example uses the IDXWHERE= table option to tell SAS to decide which index is the best to optimize the WHERE clause. SAS then disregards the possibility that a sequential search of the data set might be more resource-efficient:

```
create table mydata.empnew
   as select * from mydata.employee {option idxwhere=yes}
   where empnum < 2000;
```

Example 2: Specifying No Index Usage

This example uses the IDXWHERE= table option to tell SAS to ignore any index and to satisfy the conditions of the WHERE clause with a sequential search of the data set:

```
create table mydata.empnew
   as select * from mydata.employee {option idxwhere=no}
   where empnum < 2000;
```

See Also

Table options:

- “IDXNAME= Table Option” on page 1506
- “WHERENOINDEX= Table Option” on page 1541

IN= Table Option

Creates an integer variable that indicates whether the table contributed data to the current row.

Restriction: Use with the SET and MERGE statements only.

Data source: All

Syntax

IN=*variable*

Required Argument

variable
names the new variable whose value indicates whether that input table contributed data to the current row. Within a DS2 program, the value of the variable is 1 if the table contributed to the current row, and 0 otherwise.

Interaction: If the variable is not explicitly declared, it is automatically declared in the local scope of the SET or MERGE statement as INTEGER.

Data type: BIGINT, INTEGER, SMALLINT, TINYINT

Details

Specify the IN= table option in parentheses after a table name in the SET or MERGE statements. Values of IN= variables are available to program statements during the time the DS2 program is running, but the variables are not included in the table that is being created. To capture the value of the IN= variable in the table being created, assign it another variable.

When you use IN= with BY-group processing, the IN= variable is set to 1 if that table contributed to the current row. The IN= variable is set to 0 if the table did not contribute to the current row. The IN= variable is always set to 1 or 0 by the SET or MERGE statement, but it can be changed by subsequent programming logic.

Note: If the IN= variable is set before the SET or MERGE statement, that value is lost during execution of the SET or MERGE statement.

Example

The following example illustrates the IN= table option.

```
data _null_;
   dcl int gro;
   method run();
      dcl smallint gpo;
      dcl tinyint gpf;
      set gas_price_option (in=gpo) gas_rbid_option (in=gro)
         gas_price_forward (in=gpf);
      put gpo= gro= gpf=;
   end;
enddata;
```

- “SET Statement” on page 1430

INLINE Table Option

Specifies that the package or thread source code is not saved to a table for reuse and is validated and compiled only when loaded by a data program.

Restriction: Use with PACKAGE and THREAD statements only.

Data source: All

Syntax

INLINE

Details

By default, DS2 attempts to validate and compile package and thread source code and save it to a table. When you specify the INLINE table option, the following actions occur:

- Package and thread source code is stored in memory.
- Package and thread source code is not written to a table for future use.
- Package and thread source code is not validated and compiled if it is not loaded by a data program.

When running with PROC DS2, inlined package and thread source code is available only from the point that it is defined until the end of the current RUN block. At the end of a RUN block, inlined package and thread source code is deleted.

Consider the following example. The declaration of **mypkg** variable **p1** succeeds because the data program is defined in the same RUN block as package **mypkg**. The declaration of **mypkg** variable **p2** fails because the package, **mypkg**, is not defined in this RUN block.

```
package mypkg / inline;
method mypkg();
   put 'constructing mypkg instance';
end;
endpackage;

data _null_;
   dcl package mypkg p1();  /* OK */
enddata;

run;

data _null_;
   dcl package mypkg p2();  /* ERROR */
enddata;

run;
```

Example

In the following example, the INLINE table option is used to suppress saving the package and thread source code.

```
package pkg1 / inline;
  method pkg1();
    put 'hello from pkg1';
  end;
endpackage;

package pkg2 / inline;
  method pkg2();
    dcl package pkg1 p1();
    put 'hello from pkg2';
```

```
  end;
endpackage;

package pkg3 / inline;
  method pkg3();
    dcl package pkg1 p1();
    dcl package pkg2 p2();
    put 'hello from pkg3';
  end;
endpackage;

thread thd1 / inline;
  dcl double x;
  method init();
    put 'BEGIN EXPECTED OUTPUT';
    put 'hello from thd1 ';
    put 'hello from pkg1 ';
    put 'hello from pkg1 ';
    put 'hello from pkg2 ';
    put 'hello from pkg3 ';
    put 'hello from thd1';
    put 'END EXPECTED OUTPUT';
    put;
    put 'BEGIN TEST OUTPUT';
  end;

  method run();
    dcl package pkg3 p3();
  end;

  method term();
    put 'END TEST OUTPUT';
  end;
endthread;

data _null_;
  dcl thread thd1 t();

  method run();
    set from t threads=1;
  end;
enddata;
run;
```

The following lines are written to the SAS log:

```
BEGIN EXPECTED OUTPUT
hello from thd1
hello from pkg1
hello from pkg1
hello from pkg2
hello from pkg3
hello from thd1
END EXPECTED OUTPUT

BEGIN TEST OUTPUT
hello from pkg1
hello from pkg1
hello from pkg2
hello from pkg3
END TEST OUTPUT
```

If the INLINE table option were not used, the package and thread code would be saved to a temporary table and you would also see these lines written to the SAS log:

```
NOTE: Created package pkg1 in data set work.pkg1.
NOTE: Created package pkg2 in data set work.pkg2.
NOTE: Created package pkg3 in data set work.pkg3.
NOTE: Created thread thd1 in data set work.thd1.
```

IOBLOCKSIZE= Table Option

Specifies the number of rows in a block to be used in an I/O operation.

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SPD Engine data set, SPD Server table

Syntax

IOBLOCKSIZE= *n*

Arguments

n

specifies the size of the block in bytes. The default value is smallest block size supported by the data source.

Details

The software reads and stores rows in the table in blocks. IOBLOCKSIZE= is useful on compressed or encrypted tables. The software does not use IOBLOCKSIZE= on noncompressed or nonencrypted tables.

For tables that you compress or encrypt, the IOBLOCKSIZE= specification determines the number of rows to include in the block. The specification applies to block compression as well as data I/O to and from disk. The IOBLOCKSIZE= value affects the table's organization on disk.

When using compression or encryption, specify an IOBLOCKSIZE= value that complements how the data is to be accessed, sequentially or randomly. Sequential access or operations requiring full table scans favor a large block size. In contrast, random access favors a smaller block size. On SPD Engine, a large block size would be 131,072 bytes. The smallest allowed value is 32,768 bytes. For SPD Server, a large block size is 64,000 bytes. The smallest allowed value is 8,000 bytes.

See Also

Table Options:

- "COMPRESS= Table Option" on page 1490
- "ENCRYPT= Table Option" on page 1497
- "PADCOMPRESS= Table Option" on page 1523

KEEP= Table Option

For an input table, specifies the columns to process; for an output table, specifies the columns to write to the table.

Data source: All

Syntax

KEEP=(*column-list*)

Required Argument

column-list
specifies the names of the columns to keep in the output table.

Restriction Numbered range lists in the format *col1–col5* and name prefix lists in the format *col:* are not supported.

Details

The KEEP= table option specifies that all columns in the *column-list* should be included in the creation of output rows. Normally, all columns in the program data vector are included in the output rows. When the KEEP= table option is specified, all columns that are not included in the KEEP= table option are dropped from the output rows.

If the KEEP= table option is associated with an input table, only the columns that are specified by the KEEP= table option are available for processing during program execution.

Only global variables, by default, are included in the output. Local variables used for program loops and indexes do not need to be explicitly dropped from the output.

Comparisons

The KEEP= table option differs from the KEEP statement in these ways:

- In DS2 programs, the KEEP= table option can apply to both input and output tables. The KEEP statement applies only to output tables.
- In DS2 programs, when you create multiple output tables, use the KEEP= table option to write different columns to different tables. The KEEP statement applies to all output tables.
- The DROP= table option specifies columns to omit during processing or to omit from the output table.

Example

In this example, only IDNUM and SALARY are read from PAYROLL, and they are the only variables in PAYROLL that are available for processing.

```
data bonus;
   method run();
      set payroll(keep=(idnum salary));
      bonus=salary*1.1;
   end;
enddata;
```

See Also

Table Options:

- “DROP= Table Option” on page 1495

LABEL= Table Option

Specifies a label for a table.

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set

Syntax

LABEL=*'label'*

Required Argument

'label'
specifies a text string of up to 256 characters. If the label text contains single quotation marks, use double quotation marks around the label, or use two single quotation marks in the label text and enclose the string in single quotation marks. To remove a label from a table, assign a label that is equal to a blank that is enclosed in quotation marks.

Details

You can use the LABEL= option on both input and output tables. When you use LABEL= on input tables, it assigns a label for the table for the duration of the DS2 program. When it is specified for an output table, the label becomes a permanent part of that table.

A label assigned to a table remains associated with that table when you update a table in place. However, a label is lost if you use a table with a previously assigned label to create a new table in the DS2 program. For example, a label previously assigned to table ONE is lost when you create the new output table ONE:

```
data one;
   set one;
enddata;
```

Comparisons

The LABEL= option in the HAVING clause of the DECLARE statement also enables you to assign labels to variables.

Example

These examples assign labels to tables:

```
data w2 (label = '2009 W2 Info, Hourly);
data new (label = 'Sales'' list');
data acct (label = "Hillside''s Daily Account");
data sales (label = 'May (South)');
```

LOCKTABLE= Table Option

Places shared or exclusive locks on tables.

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set

Syntax

LOCKTABLE=SHARE | EXCLUSIVE

Required Argument

SHARE | EXCLUSIVE
specifies whether a table is locked in shared mode or exclusively.

Note: In shared mode, other users or processes can read data from the tables, but are prevented from updating data. If a table is locked exclusively, other users cannot access any table that you open.

Details

You can lock tables only if you are the owner or have been granted the necessary privilege.

If you use PROC DS2, the default value for the LOCKTABLE option is EXCLUSIVE.

When specifying the LOCKTABLE= table option in an embedded FedSQL statement, use FedSQL table option syntax. For an example, see the "SET Statement" on page 1430

When the same table is referenced more than once, LOCKTABLE must be specified for each use of a table.

ORHINTS= Table Option

Specifies Oracle hints to pass to Oracle from FedSQL.

Valid in: DELETE statement, INSERT statement, SELECT statement, UPDATE statement

Category: Data Control

Restriction: This table option is not supported on the CAS server.

Data source: Oracle

Syntax

ORHINTS=*'/* Oracle-hint */'*

Arguments

Oracle-hint
specifies an Oracle hint for the FedSQL language processor to pass to the DBMS as part of a query. If you do not specify a hint, FedSQL does not send any hints to Oracle. For more information, see *SAS Federation Server: Administrator's Guide*.

Details

The ORHINTS= table option is used in conjunction with the DRIVER_TRACE= and DRIVER_TRACEFILE= data source connection options. PROC FEDSQL and PROC DS2 do not support use of data source connection options.

Example: Using the ORHINTS= Option

These examples show how to specify ORHINTS=:

```
select * from test{options orhints='/* dummy hint */'} ;

update test{options orhints='/* dummy hint */'}  set c1=1;

insert into test{options orhints='/* dummy hint */'}  values (100);

delete from test{options orhints='/* dummy hint */'} ;
```

ORNUMERIC= Table Option

Specifies how numbers read from or inserted into the Oracle NUMBER column are treated.

Category: Table Control

Defaults: Starting in 2025.08: NO when BULKLOAD=YES is in effect. Otherwise, YES.
In prior releases: YES

Restriction: This table option is not supported on the CAS server.

Data source: Oracle

Data type: DECIMAL, NUMERIC

Syntax

ORNUMERIC=YES | NO

Arguments

NO
Indicates that the numbers are treated as TKTS_DOUBLE values. They might not have precision beyond 14 digits.

YES
Indicates that non-integer values with explicit precision are treated as TKTS_NUMERIC values.

Details

This option can be specified as both a connection option and a table option. When specified as both connection and table option, the table option value overrides the connection option. In 2025.07 and prior releases, this option defaults to YES so that a NUMBER column with precision or scale is described as TKTS_NUMERIC. Starting in 2025.08, this option defaults to NO when BULKLOAD=YES is specified. Otherwise, it defaults to YES.

OVERWRITE= Table Option

For a table, drops the output table before the replacement output table is populated with rows; for packages and threads, drops the existing package or thread if a package or thread by the same name exists.

Restriction: This table option is not supported on the CAS server. By default, tables in CAS are always overwritten.

Data source: All

Syntax

OVERWRITE=YES | NO

Required Argument

YES | NO
specifies whether the output table is deleted before a replacement output table is created or whether a package or thread is dropped.

CAUTION
For tables, use the OVERWRITE=YES statement only with data that is backed up or with data that you can reconstruct. Because the output table is deleted first, data will be lost if a failure occurs while the output table is being written.

Default NO

Details

Details for Tables

By default, in DS2, a table is not overwritten unless the OVERWRITE= table option is set to YES. If the output table exists and the OVERWRITE= table option is set to NO, an error occurs because the existing table is not overwritten.

Details for Packages

If you set OVERWRITE=YES in a PACKAGE statement and a DS2 thread or a regular table exists with the same name as the package being created, the table is not dropped. Only the package is dropped.

Details for Threads

If you set OVERWRITE=YES in a THREAD statement and a DS2 package or a regular table exists with the same name as the thread being created, the table will not be dropped. Only the thread is dropped.

Examples

Example 1: Using DROP, KEEP, and OVERWRITE

The following example uses the DROP=, KEEP=, and OVERWRITE= table options for tables **a** and **b**.

```
data
   a(keep=x overwrite=yes)
   _rowset_(drop=(x z))
   b(keep=z overwrite=yes);
   dcl double x y z;
   method init();
      do x = 1 to 10;
         y = 2*x;
         z = 3*x;
         output;
      end;
   end;
enddata;
run;
data;
   method run();
      set a;
   end;
enddata;
run;
data;
   method run();
      set b;
   end;
enddata;
run;
```

Example 2: Overwriting a Table

The following example creates a table, and then attempts to overwrite it without OVERWRITE=YES.

```
data a;
   method init();
      do x = 1 to 10;
         y = 2*x;
         z = 3*x;
         output;
      end;
   end;
enddata;
run;
/* This program fails because it is impossible to overwrite table A */
data a;
   method run();
      x = y + z;
      output;
   end;
enddata;
```

```
run;
/* This program deletes (drops) table A before attempting to create it, */
/*  so the program executes without error.  If there is an error during
/* execution, the old version of A is lost.  */
data a(overwrite=yes);   method run();
      x = y + z;
      output;
   end;
enddata;
run;
```

PADCOMPRESS= Table Option

Specifies the number of bytes to add to compressed blocks in an SPD Engine data set that is opened for OUTPUT or UPDATE.

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SPD Engine data set

Syntax

PADCOMPRESS= *n*

Arguments

n
specifies the number of bytes to add. The default number is 0 (zero).

Details

Compressed SPD Engine data sets occupy blocks of space on the disk. The size of a block is derived from the IOBLOCKSIZE= table option that is specified when the data set is created. When the data set is updated, a new block fragment might need to be created to hold the update. More updates might then create new fragments, which, in turn, increases the number of I/O operations needed to read a data set.

By increasing the block padding in certain situations where many updates to the data set are expected, fragmentation can be kept to a minimum. However, adding padding can waste space if you do not update the data set.

You must weigh the cost of padding all compression blocks against the cost of possible fragmentation of some compression blocks.

Specifying the PADCOMPRESS= table option when you create or update a data set adds space to all of the blocks as they are written back to the disk. The PADCOMPRESS= setting is not retained in the data set's metadata.

See Also

Table Options:

- "COMPRESS= Table Option" on page 1490
- "IOBLOCKSIZE= Table Option" on page 1514

PARTSIZE= Table Option

Specifies the size of the table partitions.

Valid in: CREATE TABLE statement

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SPD Engine data set, SPD Server table

Syntax

PARTSIZE= *n*

Arguments

n

specifies the size of the partition.

Requirements The size can be specified in megabytes, gigabytes, and terabytes. If *n* is specified without M, G, or T, the default is megabytes. For example, PARTSIZE=128 is the same as PARTSIZE=128M. For SPD Engine data sets, the default value is 128 megabytes. The maximum value is 8,796,093,022,207 megabytes. For SPD Server tables, the default value is the setting of the MINPARTSIZE= server option. If the MINPARTSIZE= server option is not set, the default is 16 megabytes.

When creating an SPD Engine data set, if the row length is greater than 65K, you might find that the PARTSIZE= that you specify and the actual partition size do not match. To get these numbers to match, specify a PARTSIZE= that is a multiple of 32 and the row length.

Details

For more information, see “PARTSIZE= Data Set Option in *SAS Scalable Performance Data Engine: Reference* and “PARTSIZE= Table Option” in *SAS Scalable Performance Data Server: User’s Guide*, as appropriate.

POINTOBS= Table Option

Specifies whether SAS creates compressed data sets whose observations can be randomly accessed or sequentially accessed.

Category: Table Control

Restrictions: This table option is not supported on the CAS server.
Use with output tables only.

Interaction: Used with COMPRESS= table option

Data source: SAS data set

Syntax

POINTOBS= YES | NO

Syntax Description

YES
causes the FedSQL language to produce a compressed data set that might be randomly accessed by observation number. This is the default.

Here are examples of accessing data directly by observation number:

- the POINT= option of the MODIFY and SET statements in the DATA step
- going directly to a specific observation number with PROC FSEDIT.

> **TIP** Specifying POINTOBS=YES does not affect the efficiency of retrieving information from a data set. It does increase CPU usage by approximately 10% when creating a compressed data set and when updating or adding information to it.

NO
suppresses the ability to randomly access observations in a compressed data set by observation number.

TIP Specifying POINTOBS=NO is desirable for applications where the ability to point directly to an observation by number within a compressed data set is not important. If you do not need to access data by observation number, then you can improve performance by approximately 10% by specifying POINTOBS=NO:

- when creating a compressed data set
- when updating or adding observations to it

Details

Note that REUSE=YES takes precedence over POINTOBS=YES. For example:

```
create table test{options compress=yes pointobs=yes reuse=yes};
```

This example code results in a data set that has POINTOBS=NO. Because POINTOBS=YES is the default when you use compression, REUSE=YES causes POINTOBS= to change to NO.

See Also

Table Options:

- “COMPRESS= Table Option” on page 1490
- “REUSE= Table Option” on page 1533

POST_TABLE_OPTS= Table Option

Allows database-specific options to be placed after the table name in the DATA statement.

Category:	Table Control
Default:	None
Restriction:	This table option is not supported on the CAS server.
Data source:	Hive, Spark
See:	“DBCREATE_TABLE_OPTS= Table Option” on page 1493 “PRE_TABLE_OPTS= Table Option” on page 1527

Syntax

POST_TABLE_OPTS=*"DBMS-SQL-options"*

Required Argument

"DBMS-SQL-options"
specifies additional database-specific options to be placed after the table name in a DATA statement. You can use single or double quotation marks around the DBMS value.

Details

You can use the POST_TABLE_OPTS= table option alone or with these related table options: PRE_TABLE_OPTS= and POST_STMT_OPTS=. POST_STMT_OPTS= is an alias for DBCREATE_TABLE_OPTS=. For example, you can supply database options according to these templates:

```
data mylib.myexample (pre_table_opts='external'
                      post_table_opts='stored as orc');
           dcl float f;
           method init();
             f=11.01; output;
           end;
         enddata;
         run;

data mylib.myexample (pre_table_opts='external'
                      post_table_opts='stored as orc')
                post_stmt_options="orc"} col1(int);
           dcl float f;
           method init();
             f=11.01; output;
           end;
         enddata;
         run;
```

When all three table options are specified together, they are processed as follows:

```
DATA [PRE_TABLE_OPTIONS] mylib.myexample (col1 int) [POST_TABLE_OPTS]
[POST_STMT_OPTS/DBCREATE_TABLE_OPTS]
```

PRE_TABLE_OPTS= Table Option

Allows database-specific options to be placed before the table name in the DATA statement.

Category: Table Control

Default: None

Restriction: This table option is not supported in the CAS server.

Data source: Hive, Spark

See: "DBCREATE_TABLE_OPTS= Table Option" on page 1493
"POST_TABLE_OPTS= Table Option" on page 1526

Syntax

PRE_TABLE_OPTS=*"DBMS-SQL-options"*

Required Argument

"DBMS-SQL-options"
specifies additional database-specific options to be placed before the table name in a DATA statement. You can use single or double quotation marks around the DBMS value.

Details

You can use the PRE_TABLE_OPTS= table option alone or with these related table options: POST_TABLE_OPTS= and POST_STMT_OPTS=. POST_STMT_OPTS= is an alias for DBCREATE_TABLE_OPTS=. For example, you can supply database options according to these templates:

```
data mylib.myexample (pre_table_opts='external'
                      post_table_opts='stored as orc');
          dcl float f;
          method init();
            f=11.01; output;
          end;
        enddata;
        run;

data mylib.myexample (pre_table_opts='external'
                      post_table_opts='stored as orc')
                      post_stmt_options="orc"} col1(int);
          dcl float f;
          method init();
            f=11.01; output;
          end;
        enddata;
        run;
```

When all three table options are specified together, they are processed as follows:

```
DATA [PRE_TABLE_OPTIONS] mylib.myexample (col1 int) [POST_TABLE_OPTS]
[POST_STMT_OPTS/DBCREATE_TABLE_OPTS]
```

PW= Table Option

Assigns a READ, WRITE, and ALTER password to a SAS data set or an SPD Engine data set and enables access to the password-protected file. Specifies a key value for accessing an encrypted SPD Server table.

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set, SPD Server table

Note: Check your log after this operation to ensure that the password values are not visible. For more information, see “Blot Passwords and Encryption Key Values” in *SAS Programmer’s Guide: Essentials*.

Syntax

PW= *password* | *key-value*

Arguments

password
must be a valid SAS name.

key-value
must be a valid SAS name.

Details

The PW= table option applies to a SAS data set, an SPD Engine data set, and an SPD Server table. For a SAS data set and SPD Engine data set, you can use this option to assign a password to the data set or to access a password-protected data set. When a data set that is protected by a password is replaced, the new data set inherits the password.

Note: A SAS password does not control access to a SAS file beyond the SAS system. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside of SAS.

For SPD Server tables, you can use the PW= option to access an SPD Server table that is already encrypted. The PW= option enables access to table files that are protected by the SAS proprietary encryption algorithm.

Examples

Example 1: Assigning a Password or Encryption Key with PW=

```
create table myfiles.mytable {options pw=green}(column1 double);
```

Example 2: Specifying a Password or Encryption Key with PW=

```
select * from myfiles.mytable {option pw=green};
```

READ= Table Option

Assigns a READ password to a SAS file that prevents users from reading the file, unless they enter the password.

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set

Note: Check your log after this operation to ensure that the password values are not visible. For more information, see “Blotting Passwords and Encryption Key Values” in “Blotting Out Password and Encryption Key Values from the Log” in *SAS Programmer’s Guide: Essentials*.

Syntax

READ=*read-password*

Required Argument

read-password
must be a valid SAS name.

Details

The READ= option applies to all types of SAS files except catalogs. You can use this option to assign a password to a SAS file or to access a Read-protected SAS file. When the code is written to the SAS log, the password is blotted out. Here is an example:

```
declare package sales (read=XXXXXXX);
```

Note: A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

See Also

Table Options:

- “ENCRYPT= Table Option” on page 1497
- “PW= Table Option” on page 1529
- “WRITE= Table Option” on page 1542

READMODE= Table Option

Specifies the method to use when moving data from Google BigQuery into SAS.

Category: Table Access

Default: STANDARD

Restriction: This table option is not supported on the CAS server.

Data source: Google BigQuery

Syntax

READMODE=STANDARD | STORAGE

Optional Arguments

STANDARD
uses the SAS/ACCESS method to move data into SAS.

STORAGE
uses the Storage API for Google to move data into SAS.

Details

READMODE=STORAGE is faster than READMODE=STANDARD.

RENAME= Table Option

Changes the name of a column.

Data source: All

Syntax

RENAME=(*old-name* { = | **AS** } *new-name* [...*old-name* { = | AS } *new-name*])

Required Arguments

old-name
the column that you want to rename.

new-name
the new name of the column. It must be a valid name for the data source.

Details

The RENAME= table option enables you to change the names of one or more columns.

If you use RENAME= when you create a table, the new column name is included in the output table. If you use RENAME= on an input table, the new name is used in DS2 programming statements.

If you use RENAME= in the same DS2 program with either the DROP= or the KEEP= table option, the DROP= and the KEEP= table options are applied before RENAME=. You must use the old name in the DROP= and KEEP= table options. You cannot drop and rename the same column in the same statement.

In addition to changing the name of a column, RENAME= also changes the label for the column.

Comparisons

- The RENAME= table option differs from the RENAME statement in the following ways.
  - The RENAME statement applies to all output tables. If you want to rename different columns in different tables, you must use the RENAME= table option.
  - The RENAME= table option enables you to specify the columns that you want to rename for each input or output table. Use it in input tables to rename columns before processing.
  - If you use both the RENAME statement and RENAME= output table option, the RENAME statement has precedence. If X is renamed to Y with a RENAME statement and X is renamed to Z with a RENAME= table option, the RENAME statement takes precedence and X is renamed to Y.
- Use the RENAME statement or the RENAME= table option when program logic requires that you rename columns such as two input tables that have columns with the same name.

Examples

Example 1: Renaming a Column at Time of Output

This example uses RENAME= in the DATA statement to show that the column is renamed when it is written to the output table. The column keeps its original name, X, during DS2 processing.

```
data two(rename=(x=keys))
   method run();
      set one;
      z=x+y;
   run;
enddata;
```

Example 2: Renaming a Column at Time of Input

This example renames column X to a column named KEYS in the SET statement, which is a rename before DS2 processing. KEYS, not X, is the name to use for the column for DS2 processing.

```
data three;
   method run();
      set one(rename=(x AS keys));
      z=keys+y;
   run;
enddata;
```

REUSE= Table Option

Specifies whether new rows can be written to freed space in a compressed SAS data set.

Category: Table Control

Restrictions: This table option is not supported on the CAS server.
Use with output data sets only

Data source: SAS data set

Syntax

REUSE= NO | YES

Arguments

NO
does not track and reuse space in a compressed SAS data set. New rows are appended to the existing data set. Specifying NO results in less efficient data storage if you delete or update many rows in the data set.

YES
tracks and reuses space in a compressed SAS data set. New rows are inserted in the space that is freed when other rows are updated or deleted.

If you plan to use operations that add rows to the end of a compressed data set, use REUSE=NO. REUSE=YES causes new rows to be added wherever there is space in the file, not necessarily at the end of the file.

Details

By default, new rows are appended to an existing compressed data set. If you want to track and reuse free space by deleting or updating other rows, use the REUSE= table option when you create a compressed SAS data set.

The REUSE= table option has meaning only when you are creating a new data set with the COMPRESS=YES option. Using the REUSE= table option when you are accessing an existing SAS data set has no effect.

See Also

Table Options:

- "COMPRESS= Table Option" on page 1490
- "POINTOBS= Table Option" on page 1525

STARTOBS= Table Option

Specifies the starting row number in a user-defined range of rows to be processed.

Valid in: SELECT statement

Category: Observation Control

Restrictions: This table option is not supported on the CAS server.
Use with input data sets only

Data source: SPD Engine data set, SPD Server tables

Syntax

STARTOBS= *n*

Arguments

n
is the number of the starting row.

Details

The software processes the entire data set unless you specify a range of rows with the STARTOBS= and ENDOBS= options. If the ENDOBS= option is used without the STARTOBS= option, the implied value of STARTOBS= is 1. When both options are used together, the value of STARTOBS= must be less than the value of ENDOBS=.

In contrast to the SAS software options FIRSTOBS= and OBS=, the STARTOBS= and ENDOBS= options can be used for WHERE clause processing in addition to table input operations. When STARTOBS= is used in a WHERE expression, the STARTOBS= value represents the first row on which to apply the WHERE expression.

See Also

Table Options:

- "ENDOBS= Table Option" on page 1502

SCANSTRINGCOLUMNS= Table Option

Specifies whether to determine the maximum length of character columns in a database table or a query.

Category: Table Access

Aliases: SCAN_STRINGS=
SCAN_STRING_COLUMNS=
SCANSTRINGCOLUMNS=

Default: NO

Data source: Google BigQuery

Syntax

SCANSTRINGCOLUMNS=NO | YES

Required Arguments

NO
specifies that character columns are not scanned before loading data.

YES
specifies to scan the character columns to determine their actual maximum length before loading data.

Details

Character data in Google BigQuery is stored in STRING columns, which do not have a fixed length. The MAX_CHAR_LEN= LIBNAME option is used to specify the maximum column lengths in a BigQuery table. When a value is not specified for MAX_CHAR_LEN=, the default value of 16,384 characters is used. The default setting is large to avoid truncation.

The SCANSTRINGCOLUMNS= table option enables you to override the setting in the MAX_CHAR_LEN= LIBNAME option for a table. SCANSTRINGCOLUMNS= gets the actual maximum lengths for the selected columns. Using this option can reduce the size of the resulting table and can accelerate the loading process. This option can be specified for any table, but the best performance improvement occurs for larger tables that have many character columns.

See Also

"SCANSTRINGCOLUMNS= LIBNAME Statement Option" in *SAS/ACCESS for Relational Databases: Reference*

TABLE_TYPE= Table Option

Specifies the type of table storage FedSQL will use when creating tables in SAP HANA.

Valid in:	CREATE TABLE statement
Category:	Data Access
Restriction:	This table option is not supported on the CAS server.
Interactions:	GLOBAL and GLOBAL TEMPORARY have the same behavior LOCAL and LOCAL TEMPORARY have the same behavior
Data source:	SAP HANA

Syntax

TABLE_TYPE= [COLUMN | GLOBAL | GLOBAL TEMPORARY | LOCAL | LOCAL TEMPORARY | ROW]

Arguments

COLUMN
creates a table using column-based storage in SAP HANA.

GLOBAL | GLOBAL TEMPORARY
creates a global, temporary table in SAP HANA. The tables are globally available; however, the data is visible only in the current session.

LOCAL | LOCAL TEMPORARY
creates a local, temporary table in SAP HANA. The table definition and data are visible only in the current session.

ROW
creates a table using row-based storage in SAP HANA.

Details

The SAP HANA TABLE_TYPE= option is available as a connection option and as a table option. If neither are specified, tables that are created in SAP HANA follow the SAP HANA default for row or column store.

See Also

Table Options:

- "DBCREATE_TABLE_OPTS= Table Option" on page 1493

THREADNUM= Table Option

Specifies the maximum number of I/O threads the SPD Engine can spawn for processing an SPD Engine data set.

Category: Table Control

Restriction: This table option is not supported on the CAS server.

Data source: SPD Engine data set

Syntax

THREADNUM= *n*

Arguments

n
specifies the number of threads. The default is the value of the SPDEMAXTHREADS= system option, if set. Otherwise, the default is two times the number of CPUs on your computer.

Details

THREADNUM= enables you to specify the maximum number of I/O threads that the SPD Engine spawns for processing an SPD Engine data set. The THREADNUM= value applies to any of the following SPD Engine I/O processing:

- WHERE expression processing
- parallel index creation
- I/O requested by thread-enabled applications

Adjusting THREADNUM= enables the system administrator to adjust the level of CPU resources the SPD Engine can use for any process. For example, in a 64-bit processor system, setting THREADNUM=4 limits the process to, at most, four CPUs, thereby enabling greater throughput for other users or applications.

When THREADNUM= is greater than 1, parallel processing is likely to occur. Therefore, physical order might not be retained in the output. Setting THREADNUM=1 means that no parallel processing occurs

You can also use this option to explore scalability for WHERE expression evaluations.

SPDEMAXTHREADS=, a configurable system option, imposes an upper limit on the consumption of system resources and therefore constrains the THREADNUM= value.

TYPE= Table Option

Specifies the data set type for a specially structured SAS data set.

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set

Syntax

TYPE=*data-set-type*

Required Argument

data-set-type
specifies the special type of the data set.

Details

Use the TYPE= table option in a DS2 program to create a special SAS data set in the proper format, or to identify the special type of the SAS data set in a procedure statement.

You can use the CONTENTS procedure to determine the type of a data set.

Most SAS data sets do not have a specified type. However, there are several specially structured SAS data sets that are used by some SAS/STAT procedures. These SAS data sets contain special variables and observations, and they are usually created by SAS statistical procedures.

Other values are available in other SAS software products and are described in the appropriate documentation.

Note: If you use a DS2 program with a SET statement to modify a special SAS data set, you must specify the TYPE= option in the DATA statement. The *data-set-type* is not automatically copied to the data set that is created.

See Also

Statements:

- "SET Statement" on page 1430

UNIQUESAVE= Table Option

Specifies to save observations with nonunique key values (the rejected observations) to a separate data set when inserting observations into data sets with unique indexes.

Valid in: INSERT statement

Category: User Control of SAS Index Usage

Restriction: This table option is not supported on the CAS server.

Interaction: Used in conjunction with SPDSUSDS= automatic macro variable

Data source: SPD Engine data set

Syntax

UNIQUESAVE= YES | NO

Arguments

YES
writes rejected observations to a separate, system-created table that can be accessed by a reference to the macro variable SPDSUSDS=.

NO
does not write rejected observations to a separate table (that is, ignores nonunique key values).

Details

When observations are inserted into a data set that has a unique index, the rejected observations are ignored. With UNIQUESAVE=YES, the rejected observations are saved to a separate data set whose name is stored in the macro variable SPDSUSDS. You can specify the macro variable in place of the data set name to identify the rejected observations.

USER= Table Option

Specifies the HDFS user name.

Category: Bulk Loading

Alias: USERID=, UID=

Restriction: This table option is not supported on the CAS server.

Requirement: Must be specified within the "BULKOPTS= Table Option" in *SAS FedSQL Language Reference*.

Interaction: (Optional) Use with "PASSWORD= Table Option" in *SAS FedSQL Language Reference*.

Data source: Impala

Syntax

USER=*HDFS-user*

Arguments

HDFS-user
specifies the name that represents the HDFS user. Quotation marks around the value are optional, unless the name contains spaces.

Example

```
BULKLOAD=YES BULKOPTS=(USER=HADOOP PWD="hdfs-password" CFG="config-path")
```

See Also

Table Options:

- "BULKLOAD= Table Option" on page 1487
- "PASSWORD= Table Option" in *SAS FedSQL Language Reference*

WHERENOINDEX= Table Option

Specifies a list of indexes to exclude when making WHERE expression evaluations.

Category: User Control of SAS Index Usage

Restrictions: This table option is not supported on the CAS server.
Cannot be used with IDXWHERE=NO

Data source: SPD Engine data set

Syntax

WHERENOINDEX= (*name1 name2*...)

Arguments

(name1 name2...)
specifies a list of index names that you want to exclude from use.

See Also

Table Options:

- "IDXWHERE= Table Option" on page 1508

WRITE= Table Option

Assigns a WRITE password to a SAS file that prevents users from writing to a file, unless they enter the password.

Restriction: This table option is not supported on the CAS server.

Data source: SAS data set, SPD Engine data set

Note: Check your log after this operation to ensure that the password values are not visible. For more information, see "Blotting Passwords and Encryption Key Values" in "Blotting Out Password and Encryption Key Values from the Log" in *SAS Programmer's Guide: Essentials*.

Syntax

WRITE=*write-password*

Required Argument

write-password
must be a valid SAS name.

Details

The WRITE= option applies to all types of SAS files except catalogs. You can use this option to assign a password to a SAS file or to access a Write-protected SAS file. When the code is written to the SAS log, the password is blotted out. Here is an example:

```
drop thread job2a (write=XXXXXXX);
```

Note: A SAS password does not control access to a SAS file beyond SAS. You should use the operating system-supplied utilities and file-system security controls in order to control access to SAS files outside SAS.

DS2 Datagrid Package Methods, Operators, and Statements

Dictionary

APPEND Method

Appends the specified source data grid to the specified target data grid.

Applies to: Datagrid Package

Returned data type: INTEGER

Notes: The columns in the two data grids do not need to match. This method returns the number of rows in the resulting target data grid. If an error occurs, this method returns -1.

When you use the append method with a headless data grid, it is important to consider the column data types. If the column data types do not match between the two data grids, the source column type is inferred by the type of the corresponding column in the target data grid. See Example 3 for more information.

Syntax

package.**APPEND**(*dgSource* | *JSON_string*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgSource
specifies the variable name of the source data grid.

JSON_string
specifies a JSON character string that contains the data for the data grid. You can specify a literal value in single quotation marks, or you can specify a variable that evaluates to a JSON character string. For more information about the data grid JSON format, see "About Data Grid JSON Representation" in *SAS DS2 Programmer's Guide*.

Examples

Example 1: Append

In this example, dataGrid_A is the target and dataGrid_B is the source. Here are the contents of each data grid:

Table 14.1 *dataGrid_A*

a	b	c
Aa1	Ab1	Ac1
Aa2	Ab2	Ac2

Table 14.2 *dataGrid_B*

e	d	c	a
Be1	Bd1	Bc1	Ba1
Be2	Bd2	Bc2	Ba2
Be3	Bd3	Bc3	Ba3

The following operation is performed:

```
dataGrid_A.append(dataGrid_B)
```

Here is the resulting data grid:

Table 14.3 *dataGrid_A*

a	b	c	e	d
Aa1	Ab1	Ac1	null	null
Aa2	Ab2	Ac2	null	null
Ba1	null	Bc1	Be1	Bd1

a	b	c	e	d
Ba2	null	Bc2	Be2	Bd2
Ba3	null	Bc3	Be3	Bd3

Note: This example uses data grid objects. The result is the same for data grids that are defined using serialized JSON strings.

Example 2: Headless Data Grid

In this example, the data grid that is shown in Table 14.16 includes only row data. The column header metadata is not included. This is known as a *headless* data grid.

Here is dataGrid_B presented as a headless data grid in JSON format:

```
[{"data":[  ["Be1","Bd1","Bc1","Ba1"],  ["Be2","Bd2","Bc2","Ba2"],
["Be3","Bd3","Bc3","Ba3"] ]}]
```

Here is dataGrid_B presented as a headless data grid in a table format:

Table 14.4 *Headless dataGrid_B Table*

COL_1	COL_2	COL_3	COL_4
Be1	Bd1	Bc1	Ba1
Be2	Bd2	Bc2	Ba2
Be3	Bd3	Bc3	Ba3

When you append a headless data grid, the append method maps the destination columns to the source columns based on position. Therefore, when headless dataGrid_B is appended to Table 14.15, here is the mapping that occurs:

dataGrid_A.a <-- dataGrid_B.COL_1

dataGrid_A.b <-- dataGrid_B.COL_2

dataGrid_A.c <-- dataGrid_B.COL_3

dataGrid_A.COL_4 <-- dataGrid_B.COL_4

This is the resulting dataGrid_A JSON string:

```
[
 {"metadata":[{"A":"string"},{"B":"string"},{"C":"string"},{"COL_4":"string"}]},
 {"data":[["Aa1","Ab1","Ac1",null],["Aa2","Ab2","Ac2",null],
         ["Be1","Bd1","Bc1","Ba1"],["Be2","Bd2","Bc2","Ba2"],["Be3","Bd3","Bc3","Ba3"]]}
]
```

This is the resulting dataGrid_A table:

Table 14.5 *Resulting dataGrid_A Table*

A	B	C	COL_4
Aa1	Ab1	Ac1	null
Aa2	Ab2	Ac2	null
Be1	Bd1	Bc1	Ba1
Be2	Bd2	Bc2	Ba2
Be3	Bd3	Bc3	Ba3

Example 3: Source Column Type Inferred

This example shows that when you apply the APPEND method to a headless data grid, the source column type is inferred by the type of the corresponding column in the target data grid. Here are the data grid JSON strings that are used in this example:

dataGrid_A_json:

```
[
{"metadata":[{"A":"string"},{"B":"double"}]},
{"data":[["A1",1.11],["A2",2.22],["A3",3.33]]}
]
```

dataGrid_B_json:

```
[{"data":[["B1",10],["B2",20],["B3",30]}]
```

Suppose you apply the deserialization method to dataGrid_B_json:

```
dgB.deserialize(dataGrid_B_json)
```

It produces this data grid (*dgB*). Note that COL_2 is a long type.

Table 14.6 *dgB after Deserialization Operation*

COL_1 (*string*)	COL_2 (*long*)
B1	10
B2	20
B3	30

Assume that dataGrid_A_json is deserialized to a data grid called *dgA*. Now suppose you use the append method to append dataGrid_B_json to dgA:

```
dgA.append(dataGrid_B_json)
```

It produces this data grid. Note that the long values in dataGrid_B_json have been converted to double values.

Table 14.7 *dgA after Append Operation*

A (*string*)	B (*double*)
A1	1.11
A2	2.22
A3	3.33
B1	10.00
B2	20.00
B3	30.00

BOTTOMN Method

Sorts the target data grid in ascending order, by the specified column, and then truncates it to the first *N* rows.

Applies to: Datagrid Package

Returned data type: INTEGER

Note: This method returns the number of rows in the resulting target data grid. If an error occurs, this method returns -1.

Syntax

package.**BOTTOMN**(*dgSource*, *col*, *N*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgSource
specifies the variable name of the source data grid.

col
specifies the column, using either a name or an index value.

N
specifies the maximum number of rows to return.

CLEAR Method: Datagrid Package

Deletes all rows and all column metadata from the specified data grid.

Returned data type: INTEGER

Note: This method returns 0 (zero) if it is successful. If it is not successful, this method returns a nonzero value.

Syntax

package.**CLEAR**();

Package Variable

package
specifies a name that references the datagrid package instance.

CLEARDATA Method

Deletes all rows from the specified data grid but does not remove the column metadata.

Returned data type: INTEGER

Note: This method returns 0 (zero) if it is successful and returns a nonzero value if it is not successful.

Syntax

package.**CLEARDATA**();

Package Variable

package
specifies a name that references the datagrid package instance.

COLUMNADD Method

Adds a column of specified type to the target data grid.

Returned data type: INTEGER

Note: If the column is added, the updated total number of columns in the data grid is returned. Otherwise, -1 is returned.

Syntax

package.**COLUMNADD**(*colName*, *typeName*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

colName
specifies the name of the column.

typeName
specifies a type name value. Valid types are [string, int | integer, long, decimal | double, Boolean].

COLUMNADDCHARTYPE Method

Adds a character column to the specified data grid.

Returned data type: INTEGER

Note: If the column is added, the updated total number of columns in the data grid is returned. Otherwise, -1 is returned.

Syntax

package.**COLUMNADDCHARTYPE**(*colName*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

colName
specifies the name of the column.

COLUMNADDNUMTYPE Method

Adds a numeric column of type decimal to the specified data grid.

Returned data type: INTEGER

Note: If the column is added, the updated total number of columns in the data grid is returned. Otherwise, -1 is returned.

Syntax

package.**COLUMNADDNUMTYPE**(*colName*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

colName
specifies the name of the column.

COLUMNCLEAR Method

Clears all the rows in a data grid column.

Returned data type: INTEGER

Notes: If row index values are specified, only those rows are cleared.
This method returns 0 (zero) if the column is cleared and returns a nonzero value if an error occurs.

Syntax

package.**COLUMNCLEAR**(*col*, [*rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

col
specifies the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNCORR Method

Returns the Pearson correlation coefficient of the two specified columns.

Returned data type: DECIMAL

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNCORR**(*col1*, *col2* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col1
col2
specifies the numeric data grid columns for which you want to compute the correlation coefficient. You can specify the columns using either a name or an index value. To specify a column name, use a string value. To specify a column

index, use a numeric value. An index value must be (or evaluate to) a positive integer.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

Details

The Pearson product-moment correlation is a parametric measure of association for two variables. It measures both the strength and the direction of a linear relationship. If one variable X is an exact linear function of another variable Y, a positive relationship exists if the correlation is 1, and a negative relationship exists if the correlation is -1. If there is no linear predictability between the two variables, the correlation is 0. If the two variables jointly have a normal distribution with a zero correlation, the two variables are independent. However, correlation does not imply causality because, in some cases, an underlying causal relationship might not exist.

The formula for the Pearson product-moment correlation, denoted by ρ_{xy} is as follows:

$$\rho_{xy} = \frac{\mathrm{Cov}(x,y)}{\sqrt{\mathrm{V}(x)\mathrm{V}(y)}} = \frac{\mathrm{E}((x-\mathrm{E}(x))(y-\mathrm{E}(y)))}{\sqrt{\mathrm{E}(x-\mathrm{E}(x))^2\mathrm{E}(y-\mathrm{E}(y))^2}}$$

COLUMNCOUNT Method

Returns the number of columns in the specified data grid.

Returned data type: INTEGER

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNCOUNT**();

Package Variable

package
specifies a name that references the datagrid package instance.

COLUMNCOUNTMATCH Method

Returns the number of rows that match the specified criteria.

Returned data type: INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNCOUNTMATCH**(*cmpCol*, *operator*, *cmpValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpCol
specifies the column, using either a name or an index value, whose value is to be compared to *cmpValue*.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value of cmpCol. You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must be cmpCol, or it must evaluate to the same data type as *cmpCol*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters), matches missing values.
- For all other types, null values do not exist. If null is specified for cmpValue, it is treated as a missing value by the comparison operation.

COLUMNCOUNTMATCHBYFILTER Method

Returns the number of rows that match the specified criteria. This criteria is defined by a filter.

Returned data type: INTEGER

Notes: If an error occurs, the return value is `Missing-Value`.
Support for this method starts in 2025.02.

Syntax

Form 1: *package*.**COLUMNCOUNTMATCHBYFILTER**(*filter* [, *varList*]);

Form 2: *package*.**COLUMNCOUNTMATCHBYFILTER**(*filter*, *rowStartIndex*, *rowEndIndex* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

COLUMNCOUNTMATCHIN Method

Returns the number of matching rows in the specified column for which the comparison operation evaluates to true. Multiple values are used as the comparator in the operation. These values are defined in the first column of the data grid that is specified for the *inDatagrid* argument.

Returned data type: INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNCOUNTMATCHIN**(*cmpColumn*, *cmpOperator*, *inDatagrid* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpColumn
specifies the column, using either a name or an index value, in which to perform the comparison operation.

cmpOperator
specifies the operator to use in the comparison operation, either EQ (equal) or NEQ (not equal).

inDatagrid
specifies the data grid in which the first column contains the comparator values to use in the comparison operation.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNCOUNTMISSING Method

Returns the number of missing values for the specified criteria.

Returned data type: INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNCOUNTMISSING**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

col
specifies the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNCOUNTVALID Method

Returns the number of valid nonmissing numeric values for the specified criteria.

Returned data type: INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNCOUNTVALID**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNDELETE Method

Deletes the specified column from the specified data grid.

Category:	Create, Update, or Delete
Returned data type:	INTEGER
Note:	This method returns 0 (zero) if the column is deleted and returns a nonzero value if an error occurs.

Syntax

package.**COLUMNDELETE**(*col*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the column, using either a name or an index value.

COLUMNEXISTS Method

Returns 1 (true) if the specified column exists. Otherwise, returns 0 (false).

Category: Create, Update, or Delete

Returned data type: INTEGER

Note: This method returns 0 (zero) if the column is deleted and returns a nonzero value if an error occurs.

Syntax

package.**COLUMNEXISTS**(*colName*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

colName
specifies the name of the column.

COLUMNFREQ Operator

Returns the number of distinct values in the specified column.

Category: Statistical

Returned data type: INTEGER

Syntax

package.**COLUMNFREQ**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNINDEX Method

Returns the ordinal position of the specified column name.

Returned data type: INTEGER

Note: If an error occurs or the column name does not exist, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNIDEX**(*colName*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

colName
specifies the name of the column.

COLUMNISNUMERIC Method

Returns 1 (true) if the specified column is a numeric data type. Otherwise, returns 0 (false).

Returned data type: INTEGER

Syntax

package.**COLUMNISNUMERIC**(*col*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

COLUMNMAX Method

Returns the maximum value for the specified criteria.

Returned data type: DECIMAL

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNMAX**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMAXBOOL Method

Returns the maximum Boolean value for the specified criteria.

Returned data type: BOOLEAN

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNMAXBOOL**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMAXINT Method

Returns the maximum integer value for the specified criteria.

Returned data type: INTEGER

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNMAXINT**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMAXLONG Operator

Returns the maximum long value for the specified criteria.

Returned data type: 64-BIT INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNMAXLONG**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMAXSTRING Method

Returns the maximum string value for the specified criteria.

Returned data type: STRING

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNMAXSTRING**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMEAN Method

Returns the mean value for the specified criteria.

Returned data type: DECIMAL

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNMEAN**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMEDIAN Method

Returns the median value for the specified criteria.

Returned data type:	DECIMAL
Note:	If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNMEDIAN**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMIN Method

Returns the minimum value for the specified criteria.

Returned data type: DECIMAL

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNMIN**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMINBOOL Method

Returns the minimum Boolean value for the specified criteria.

Returned data type: BOOLEAN

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNMINBOOL**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMININT Method

Returns the minimum integer value for the specified criteria.

Returned data type: INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNMININT**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMINLONG Method

Returns the minimum long value for the specified criteria.

Returned data type: 64-BIT INTEGER

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNMINLONG**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNMINSTRING Method

Returns the minimum string value for the specified criteria.

Returned data type: STRING

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNMINSTRING**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNNAME Method

Returns the name of the column that is in the one-based ordinal position.

Returned data type: VARCHAR

Note: If the specified ordinal position does not exist, a null DS2 string is returned.

Syntax

package.**COLUMNNAME**(*colIndex*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

colIndex
specifies the index value of the column in the data grid.

COLUMNRENAME Method

Renames the specified column.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the column is renamed and returns a nonzero value if an error occurs.

Syntax

package.**COLUMNRENAME**(*col*, *newName*)

Package Variable

package
specifies the name of the datagrid package variable.

Required Arguments

col
specifies the column, using either a name or an index value.

newName
specifies the new name.

COLUMNSTDDEV Method

Returns the standard deviation of the values in the specified column.

Returned data type: DECIMAL

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**COLUMNSTDDEV**(*col* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies the name of the column, using either a name or an index value.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

COLUMNSUM Method

Returns the sum of DOUBLE values in the specified column.

Returned data type: DECIMAL

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNSUM**(*col*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies a column that contains DOUBLE values, using either a name or an index value.

Example

In this example, dataGrid_A has two columns. One column, col_a, contains DOUBLE values. The second column, col_b, contains STRING values. Therefore, in this example, COLUMNSUM can be used on col_a.

Table 14.8 *dataGrid_A*

col_a	col_b
-11.5	city
10.1	name

col_a	col_b
19.3	address

The following operation is performed.

Using column name:

```
double_sum = dataGrid_A.COLUMNSUM('col_a');
```

Using column index:

```
double_sum = dataGrid_A.COLUMNSUM('1');
```

COLUMNSUMLONG Method

Returns the sum of LONG values in the specified column.

Returned data type: 64-BIT INTEGER

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**COLUMNSUMLONG**(*col*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

col
specifies a column that contains LONG values, using either a name or an index value.

Example

In this example, dataGrid_A has two columns. One column, col_a, contains LONG values. The second column, col_b, contains STRING values. Therefore, in this example, COLUMNSUMLONG can be used on col_a.

Table 14.9 dataGrid_A

col_a	col_b
1586422	city
65246574	name
946672166	address

The following operation is performed.

Using column name:

```
long_sum = dataGrid_A.COLUMNSUMLONG('col_a');
```

Using column index:

```
long_sum = dataGrid_A.COLUMNSUMLONG('1');
```

COLUMNTYPENAME Method

Returns the type name of the specified column name.

Returned data type: VARCHAR

Note: If the specified column name does not exist, a null DS2 string is returned.

Syntax

package.**COLUMNTYPENAME**(*colName*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

colName
specifies the name of the column.

COPY Method: Datagrid Package

Creates a duplicate of the source data grid into the target data grid.

Returned data type: INTEGER

Note: This method returns the number of rows that were copied to the target data grid. If an error occurs, this method returns -1.

Syntax

package.**COPY**(*dgSource*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

dgSource
specifies the variable name of the source data grid.

DECLARE PACKAGE Statement: Datagrid Package

Creates a package variable and enables you to create an instance of the datagrid package

Syntax

Form 1: **DECLARE PACKAGE DATAGRID** *variable*();

Form 2: **DECLARE PACKAGE DATAGRID** *variable*(*name*);

Package Variable

variable
specifies a name that references the datagrid package instance.

Required Argument

name
specifies an internal name that can be used to reference the instance.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a datagrid package to create or manage a native data grid object. The datagrid package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a datagrid package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package datagrid dg;
dg = _new_ datagrid();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package datagrid dg();
```

See Also

- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: Datagrid Package" on page 1621

DESERIALIZE Method

Creates a data grid from the specified JSON string.

Returned data type: INTEGER

Notes: This method returns 0 (zero) if the data grid is created and returns a nonzero value if it is not created.

When metadata is not provided in the JSON string, the data types of the columns are inferred from the first type that is identified in the JSON processing (string, Boolean, long, decimal). If all of the items in the column are null, the type is converted to decimal.

Syntax

package.**DESERIALIZE**(*JSON_string*);

Package Variable

package
specifies the name of the datagrid package variable.

Required Argument

JSON_string
specifies a JSON character string that contains the data for the data grid. You can specify a literal value in single quotation marks, or you can specify a variable that evaluates to a JSON character string. For more information about the data grid JSON format, see "About Data Grid JSON Representation" in *SAS DS2 Programmer's Guide*.

The JSON string that represents the data grid can include any one of the following:

- both metadata and data
- metadata only
- data only

column1
column2
specifies the column names of each column in the data grid.

row1_data
row2_data
specifies the data for each row in the data grid. Separate the values for each column in a row with a comma (,). Enclose character values in double quotation marks.

Example

The first non-null data row determines the column type. In the following example, the first row is all null, which provides no type inference. In the second row, all the column types are inferred except for the third column. Because all the data in column three is null, this column type is inferred as decimal.

Here is the JSON content with all null columns:

```
json:: [{"data":[[null,null,null,null,null],
["Str_01",true,null,15,1.01],
["Str_02",false,null,77,2.02],["Str_03",false,null,93,3.03],
["Str_04",true,null,15,4.04],["Str_05",false,null,null,5.05]]}]
```

Here is the resulting data grid:

```
row[0000]: string(mv) boolean(mv) decimal(mv) long(m1v) decimal(mv)
row[0001]: string(Str_01) boolean(true) decimal(mv) long(15) decimal(1.01)
row[0002]: string(Str_02) boolean(false) decimal(mv) long(77) decimal(2.02)
row[0003]: string(Str_03) boolean(false) decimal(mv) long(93) decimal(3.03)
row[0004]: string(Str_04) boolean(true) decimal(mv) long(15) decimal(4.04)
row[0005]: string(Str_05) boolean(false) decimal(mv) long(mv) decimal(5.05)
```

DISTINCTCOUNT Method

Returns the number of unique rows in the data grid.

Returned data type: INTEGER

Note: If an error occurs, the return value is **Missing-Value**.

Syntax

package.**DISTINCTCOUNT**();

Package Variable

package
specifies a name that references the datagrid package instance.

FILTEREDCOMPARE Method

Returns the value of a compare on a specific column and row value in the datagrid.

Returned data type: Integer

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**FILTEREDCOMPARE**(*cmpColName*, *operator*, *cmpValue*, *cmpRowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpColName
specifies the column name.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value at the intersection of *cmpColName* and *cmpRowIndex*.

You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must evaluate to the same data type as the value at the intersection of *cmpColName* and *cmpRowIndex*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters) matches missing values.
- For all other types, null values do not exist. If null is specified for *cmpValue*, it is treated as a missing value by the comparison operation.

cmpRowIndex
specifies the index value of the row. An index value must be (or evaluate to) a positive integer.

FILTEREDGET Method

Returns the value of the first row in the source column for which the comparison operation evaluates to true.

Returned data type: INTEGER, DECIMAL

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**FILTEREDGET**(*cmpCol*, *operator*, *cmpValue*, *srcCol* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpCol
specifies the column, using either a name or an index value, whose value is to be compared to *cmpValue*.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value of *cmpCol*. You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must be *cmpCol*, or it must evaluate to the same data type as *cmpCol*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters), matches missing values.
- For all other types, null values do not exist. If null is specified for *cmpValue*, it is treated as a missing value by the comparison operation.

srcCol
specifies the name or index value of the column that contains the value to return. To specify a column name, use a string value. To specify a column index, use a numeric value. An index value must be (or evaluate to) a positive integer.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

FILTEREDGETBYFILTER Method

Returns the value of the first row in the source column for which the comparison operation evaluates to true. The comparison operation is defined using a filter.

Returned data type:	INTEGER, DECIMAL
Notes:	If an error occurs, the return value is `Missing-Value`. Support for this method starts in 2025.02.

Syntax

Form 1: *package*.**FILTEREDGETBYFILTER**(*filter*, *srcColName* [, *varList*]);

Form 2: *package*.**FILTEREDGETBYFILTER**(*filter*, *srcColName*, *rowStartIndex*, *rowEndIndex* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

srcColName
specifies the name of the column that contains the value to return.

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

FILTEREDGETIN Method

Returns the value of the first row in the source column for which the comparison operation evaluates to true. Multiple values are used as the comparator in the operation. These values are defined in the first column of the data grid that is specified for the *inDatagrid* argument.

Returned data type: STRING, DECIMAL

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**FILTEREDGETIN**(*cmpColumn*, *cmpOperator*, *inDatagrid*, *srcCol* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpColumn
specifies the column, using either a name or an index value, in which to perform the comparison operation.

cmpOperator
specifies the operator to use in the comparison operation, either EQ (equal) or NEQ (not equal).

inDatagrid
specifies the data grid in which the first column contains the comparator values to use in the comparison operation.

scrCol
specifies the name of the column whose value you want to know.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

FILTEREDGETINDEX Method

Returns the index of the first row for which the comparison operation evaluates to true.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the condition is not found.

Syntax

package.**FILTEREDGETINDEX**(*cmpCol*, *operator*, *cmpValue* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpCol
specifies the column, using either a name or an index value, whose value is to be compared to *cmpValue*.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value of cmpCol. You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must be cmpCol, or it must evaluate to the same data type as *cmpCol*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters), matches missing values.
- For all other types, null values do not exist. If null is specified for *cmpValue*, it is treated as a missing value by the comparison operation.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

FILTEREDGETINDEXBYFILTER Method

Returns the index of the first row for which the comparison operation evaluates to true. The comparison operation is defined using a filter.

Returned data type:	INTEGER
Notes:	This method returns 0 (zero) if the condition is not found. Support for this method starts in 2025.02.

Syntax

Form 1: *package*.**FILTEREDGETINDEXBYFILTER**(*filter* [, *varList*]);

Form 2: *package*.**FILTEREDGETINDEXBYFILTER**(*filter*, *rowStartIndex*, *rowEndIndex* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

FILTEREDGETINDEXIN Method

Returns the index of the first row for which the comparison operation evaluates to true. Multiple values are used as the comparator in the operation. These values are defined in the first column of the data grid that is specified for the *inDatagrid* argument.

Returned data type: STRING, DECIMAL

Note: This method returns 0 (zero) if the condition is not found.

Syntax

package.**FILTEREDGETINDEXIN**(*cmpColumn*, *cmpOperator*, *inDatagrid* [, *rowStartIndex*, *rowEndIndex*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpColumn
specifies the column, using either a name or an index value, in which to perform the comparison operation.

cmpOperator
specifies the operator to use in the comparison operation, either EQ (equal) or NEQ (not equal).

inDatagrid
specifies the data grid in which the first column contains the comparator values to use in the comparison operation.

Optional Arguments

rowStartIndex
specifies the row number at which to begin the operation.

rowEndIndex
specifies the row number at which to end the operation.

FILTEREDSET Method

Sets the value in the specified column to the specified value if the comparison evaluates to true.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**FILTEREDSET**(*cmpCol*, *operator*, *cmpValue*, *rowIndex*, *setCol*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpCol
specifies the column, using either a name or an index value, whose value is to be compared to *cmpValue*.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value of *cmpCol*. You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must be cmpCol, or it must evaluate to the same data type as *cmpCol*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters), matches missing values.
- For all other types, null values do not exist. If null is specified for cmpValue, it is treated as a missing value by the comparison operation.

rowIndex
specifies the row number in the data grid.

setCol
specifies the name or index value of the column to be assigned the specified value.

setValue
specifies the value to assign.

FILTEREDSETBYFILTER Method

Sets the value in the specified column to the specified value if the comparison evaluates to true. The comparison operation is defined using a filter.

Returned data type: INTEGER

Notes: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.
Support for this method starts in 2025.02.

Syntax

package.**FILTEREDSETBYFILTER**(*filter*, *rowIndex*, *setColName*, *setValue* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

rowIndex
specifies the row number in the data grid.

setColName
specifies the name of the column to be assigned the specified value.

setValue
specifies the value to assign.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

FILTEREDSETALL Method

Sets the cell in the specified column to the specified value if the specified comparison evaluates to true.

Note: This method returns the number of rows that were changed in the data grid. If an error occurs, the return value is `Missing-Value`.

Syntax

package.**FILTEREDSETALL**(*cmpCol*, *operator*, *cmpValue*, *setCol*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

cmpCol
specifies the column, using either a name or an index value, whose value is to be compared to *cmpValue*.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value of *cmpCol*. You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must be *cmpCol*, or it must evaluate to the same data type as *cmpCol*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters), matches missing values.
- For all other types, null values do not exist. If null is specified for *cmpValue*, it is treated as a missing value by the comparison operation.

setCol
specifies the name or index value of the column to be assigned the specified value.

Note: Form 2 does not support specifying a column index value.

setValue
specifies the value to assign.

FILTEREDSETALLBYFILTER Method

Sets the cell in the specified column to the specified value if the specified comparison evaluates to true. The comparison operation is defined using a filter.

Notes:
This method returns the number of rows that were changed in the data grid. If an error occurs, the return value is `Missing-Value`.

Support for this method starts in 2025.02.

Syntax

package.**FILTEREDSETALLBYFILTER**(*filter*, *setColName*, *setValue* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

setColName
specifies the name of the column to be assigned the specified value.

setValue
specifies the value to assign.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

FULLJOIN Method

Performs a full join of two data grids and populates the target data grid with the results of the join.

Returned data type: INTEGER

Notes: A row is written to the target data grid for each row in the right table and the left table. This is the case even if there are no matches between the tables. Column names that match in the left and right tables are renamed to *columnName*_R in the target data grid.

This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.

Support for Form 2 starts in 2023.03.

Syntax

Form 1: *package*.**FULLJOIN**(*dgLeft*, *colLeft*, *dgRight*, *colRight*);

Form 2: *package*.**FULLJOIN**(*dgLeft*, *dgRight*, *dgJoin*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

Examples

Note: When you perform a full join, the sort order of your data might differ from the sort order presented in these examples.

Example 1: Full Join

Here is an example of a full join. These are the source tables used in the operation:

Table 14.10 *Price Table (price)*

PRODUCT	PRICE	MATCH
Potatoes	1.001	l_1
Avocados	2.002	l_2
Kiwis	3.003	l_3
Onions	4.004	l_4

PRODUCT	PRICE	MATCH
Melons	5.005	l_5
Oranges	6.006	l_6
Tomatoes	7.007	l_7

Table 14.11 *Quantity Table (quantity)*

MATCH	PROD	QUANTITY
r_1	Melons	11
r_2	Squash	22
r_3	Kiwis	33
r_4	Potatoes	44
r_8	Broccoli	55
r_6	Avocados	66
r_8	Broccoli	77
r_5	Avocados	88
r_7	Onions	99
r_5	Pickles	100

In this example, the following operation is performed:

```
dataGrid_A.fullJoin(price, 'PRODUCT', quantity, 'PROD');
```

Here is the resulting data grid:

Table 14.12 *dataGrid_A*

PRODUCT	PRICE	MATCH	MATCH_R	PROD	QUANTITY
Potatoes	1.001	l_1	r_4	Potatoes	44
Avocados	2.002	l_2	r_6	Avocados	66
Avocados	2.002	l_2	r_5	Avocados	88
Kiwis	3.003	l_3	r_3	Kiwis	33

PRODUCT	PRICE	MATCH	MATCH_R	PROD	QUANTITY
Onions	4.004	l_4	r_7	Onions	99
Melons	5.005	l_5	r_1	Melons	11
Oranges	6.006	l_6	null	null	null
Tomatoes	7.007	l_7	null	null	null
null	null	null	r_2	Squash	22
null	null	null	r_8	Broccoli	55
null	null	null	r_8	Broccoli	77
null	null	null	r_5	Pickles	100

Example 2: Multi-Column Full Join

Here is an example of a multi-column full join. These are the source tables used in the operation:

Table 14.13 *Cost Table (cost)*

PRODUCT	TYPE	COST	MATCH
Potatoes	Russet	1.001	l_1
Potatoes	Sweet	1.011	l_1.1
Avocados	Hass	2.002	l_2
Avocados	Reed	2.022	l_2.2
Kiwis	Golden	3.003	l_3
Kiwis	Purple	3.033	l_3.3
Onions	Vidalia	4.004	l_4
Onions	Yellow	4.044	l_4.4
Melons	Honey Dew	5.005	l_5
Melons	Watermelon	5.055	l_5.5
Oranges	Blood	6.006	l_6

PRODUCT	TYPE	COST	MATCH
Oranges	Navel	6.066	l_6.6
Tomatoes	Heirloom	7.007	l_7
Tomatoes	Beefsteak	7.077	l_7.7

Table 14.14 *Amount Table (amount)*

MATCH	PROD	TYPE	AMOUNT
r_1	Melons	Watermelon	11
r_2	Squash	Butternut	22
r_3	Kiwis	Purple	33
r_4	Potatoes	Russet	44
r_8	Broccoli	Blue Wind	55
r_6	Avocados	Reed	66
r_8	Broccoli	Eastern Magic	77
r_5	Avocados	Hass	88
r_7	Onions	Vidalia	99
r_5	Pickles	Dill	100

Table 14.15 *Join Columns Table (dgJoinKeys)*

leftColumnName	rightColumnName
PRODUCT	PROD
TYPE	TYPE

In this example, the following operation is performed:

```
dataGrid_B.fullJoin(cost, amount, dgJoinKeys);
```

Here is the resulting data grid:

Table 14.16 dataGrid_B

PRODUCT	TYPE	COST	MATCH	MATCH_R	PROD	TYPE_R	AMOUNT
Potatoes	Russet	1.001	l_1	r_4	Potatoes	Russet	44
Potatoes	Sweet	1.011	l_1.1	null	null	null	null
Avocados	Hass	2.002	l_2	r_5	Avocados	Hass	88
Avocados	Reed	2.022	l_2.2	r_6	Avocados	Reed	66
Kiwis	Golden	3.003	l_3	null	null	null	null
Kiwis	Purple	3.033	l_3.3	r_3	Kiwis	Purple	33
Onions	Vidalia	4.004	l_4	r_7	Onions	Vidalia	99
Onions	Yellow	4.044	l_4.4	null	null	null	null
Melons	Honey Dew	5.005	l_5	null	null	null	null
Melons	Watermelon	5.055	l_5.5	r_1	Melons	Watermelon	11
Oranges	Blood	6.006	l_6	null	null	null	null
Oranges	Navel	6.066	l_6.6	null	null	null	null
Tomatoes	Heirloom	7.007	l_7	null	null	null	null
Tomatoes	Beefsteak	7.077	l_7.7	null	null	null	null
null	null	null	null	r_2	Squash	Butternut	22
null	null	null	null	r_8	Broccoli	Blue Wind	55
null	null	null	null	r_8	Broccoli	Eastern Magic	77
null	null	null	null	r_5	Pickles	Dill	100

FULLJOINBYFILTER Method

Performs a full join of two data grids and populates the target data grid with the results of the join. The target column and source row criteria are specified using a column keep clause and a row filter definition.

Returned data type: INTEGER

Notes: A row is written to the target data grid for each row in the right table and the left table. This is the case even if there are no matches between the tables. Column names that match in the left and right tables are renamed to *columnName*_R in the target data grid.

This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.

Support for this method starts in 2025.02.

Syntax

package.**FULLJOINBYFILTER**(*dgLeft*, *dgRight*, *keepColumns*, *filter* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

dgRight
specifies the variable name of the right data grid.

keepColumns
the list of columns to place in the result data grid. For more information, see "About the Keep Columns Syntax" in *SAS DS2 Programmer's Guide*.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects

the data type of the DS2 varList variable to be consistent with the data type of the associated column.

Examples

Note: When you perform a full join, the sort order of your data might differ from the sort order presented in these examples.

Example 1: Full Join

Here is an example of a full join. These are the source tables used in the operation:

Table 14.17 *Price Table (price)*

PRODUCT	PRICE	MATCH
Potatoes	1.001	l_1
Avocados	2.002	l_2
Kiwis	3.003	l_3
Onions	4.004	l_4
Melons	5.005	l_5
Oranges	6.006	l_6
Tomatoes	7.007	l_7

Table 14.18 *Quantity Table (quantity)*

MATCH	PROD	QUANTITY
r_1	Melons	11
r_2	Squash	22
r_3	Kiwis	33
r_4	Potatoes	44
r_8	Broccoli	55
r_6	Avocados	66

MATCH	PROD	QUANTITY
r_8	Broccoli	77
r_5	Avocados	88
r_7	Onions	99
r_5	Pickles	100

In this example, the following operation is performed:

```
dataGrid_A.fullJoinByFilter(price, quantity, '*', 'L.PRODUCT eq
R.PROD');
```

Here is the resulting data grid:

Table 14.19 *dataGrid_A*

PRODUCT	PRICE	MATCH	MATCH_R	PROD	QUANTITY
Potatoes	1.001	l_1	r_4	Potatoes	44
Avocados	2.002	l_2	r_6	Avocados	66
Avocados	2.002	l_2	r_5	Avocados	88
Kiwis	3.003	l_3	r_3	Kiwis	33
Onions	4.004	l_4	r_7	Onions	99
Melons	5.005	l_5	r_1	Melons	11
Oranges	6.006	l_6	null	null	null
Tomatoes	7.007	l_7	null	null	null
null	null	null	r_2	Squash	22
null	null	null	r_8	Broccoli	55
null	null	null	r_8	Broccoli	77
null	null	null	r_5	Pickles	100

In this example, an **`*`** (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid. Also, `varList` includes the variable called **`product`**, which is assigned the value **`Potatoes`**.

```
dataGrid_A.fullJoinByFilter(price, quantity, '*', 'L.PRODUCT eq R.PROD
& L.PRODUCT eq ?', [product]);
```

Here is the resulting data grid:

Table 14.20 *dataGrid_A*

PRODUCT	PRICE	MATCH	MATCH_R	PROD	QUANTITY
Potatoes	1.001	l_1	r_4	Potatoes	44
Avocados	2.002	l_2	null	null	null
Kiwis	3.003	l_3	null	null	null
Onions	4.004	l_4	null	null	null
Melons	5.005	l_5	null	null	null
Oranges	6.006	l_6	null	null	null
Tomatoes	7.007	l_7	null	null	null
null	null	null	r_1	Melons	11
null	null	null	r_2	Squash	22
null	null	null	r_3	Kiwis	33
null	null	null	r_8	Broccoli	55
null	null	null	r_6	Avocados	66
null	null	null	r_8	Broccoli	77
null	null	null	r_5	Avocados	88
null	null	null	r_7	Onions	99
null	null	null	r_5	Pickles	100

Example 2: Multi-Column Full Join

Here is an example of a multi-column full join. These are the source tables used in the operation:

Table 14.21 *Cost Table (cost)*

PRODUCT	TYPE	COST	MATCH
Potatoes	Russet	1.001	l_1
Potatoes	Sweet	1.011	l_1.1
Avocados	Hass	2.002	l_2

PRODUCT	TYPE	COST	MATCH
Avocados	Reed	2.022	l_2.2
Kiwis	Golden	3.003	l_3
Kiwis	Purple	3.033	l_3.3
Onions	Vidalia	4.004	l_4
Onions	Yellow	4.044	l_4.4
Melons	Honey Dew	5.005	l_5
Melons	Watermelon	5.055	l_5.5
Oranges	Blood	6.006	l_6
Oranges	Navel	6.066	l_6.6
Tomatoes	Heirloom	7.007	l_7
Tomatoes	Beefsteak	7.077	l_7.7

Table 14.22 *Amount Table (amount)*

MATCH	PROD	TYPE	AMOUNT
r_1	Melons	Watermelon	11
r_2	Squash	Butternut	22
r_3	Kiwis	Purple	33
r_4	Potatoes	Russet	44
r_8	Broccoli	Blue Wind	55
r_6	Avocados	Reed	66
r_8	Broccoli	Eastern Magic	77
r_5	Avocados	Hass	88
r_7	Onions	Vidalia	99
r_5	Pickles	Dill	100

In this example, the following operation is performed:

```
dataGrid_B.fullJoinByFilter(cost, amount, '*', 'L.PRODUCT eq R.PROD &
L.TYPE eq R.TYPE');
```

Here is the resulting data grid:

Table 14.23 *dataGrid_B*

PRODUCT	TYPE	COST	MATCH	MATCH_R	PROD	TYPE_R	AMOUNT
Potatoes	Russet	1.001	l_1	r_4	Potatoes	Russet	44
Potatoes	Sweet	1.011	l_1.1	null	null	null	null
Avocados	Hass	2.002	l_2	r_5	Avocados	Hass	88
Avocados	Reed	2.022	l_2.2	r_6	Avocados	Reed	66
Kiwis	Golden	3.003	l_3	null	null	null	null
Kiwis	Purple	3.033	l_3.3	r_3	Kiwis	Purple	33
Onions	Vidalia	4.004	l_4	r_7	Onions	Vidalia	99
Onions	Yellow	4.044	l_4.4	null	null	null	null
Melons	Honey Dew	5.005	l_5	null	null	null	null
Melons	Watermelon	5.055	l_5.5	r_1	Melons	Watermelon	11
Oranges	Blood	6.006	l_6	null	null	null	null
Oranges	Navel	6.066	l_6.6	null	null	null	null
Tomatoes	Heirloom	7.007	l_7	null	null	null	null
Tomatoes	Beefsteak	7.077	l_7.7	null	null	null	null
null	null	null	null	r_2	Squash	Butternut	22
null	null	null	null	r_8	Broccoli	Blue Wind	55

PRODUCT	TYPE	COST	MATCH	MATCH_R	PROD	TYPE_R	AMOUNT
null	null	null	null	r_8	Broccoli	Eastern Magic	77
null	null	null	null	r_5	Pickles	Dill	100

FULLJOINCOUNT Method

Returns the number of rows that would be produced by a full join operation. No data grid is affected by this operation.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.
Support for Form 2 starts in 2023.03.

Syntax

Form 1: *dgLeft*.**FULLJOINCOUNT**(*colLeft*, *dgRight*, *colRight*);

Form 2: *dgLeft*.**FULLJOINCOUNT**(*dgRight*, *dgJoin*);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

colLeft
specifies the key column in dgLeft, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in dgRight, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

FULLJOINTCOUNTBYFILTER Method

Returns the number of rows that would be produced by a full join operation. The source row criteria is specified using a row filter definition. No data grid is affected by this operation.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.
Support for this method starts in 2025.02.

Syntax

dgLeft.**FULLJOINCOUNTBYFILTER**(*dgRight*, *filter* [, *varList*]);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

dgRight
specifies the variable name of the right data grid.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

GETBOOL Method

Returns the Boolean value of the cell in the specified row and column.

Returned data type: INTEGER

Note: If an error occurs, the return value is **Missing-Value**.

Syntax

package.**GETBOOL**(*col*, *rowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

GETDOUBLE Method

Returns the decimal value of the cell in the specified row and column.

Returned data type: DECIMAL

Note: If an error occurs, the return value is **Missing-Value**.

Syntax

package.**GETDOUBLE**(*col*, *rowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

GETINT Method

Returns the integer value of the cell in the specified row and column.

Returned data type: INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**GETINT**(*col*, *rowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

GETLONG Method

Returns the long value of the cell in the specified row and column.

Returned data type: 64-BIT INTEGER

Note: If an error occurs, the return value is `Missing-Value`.

Syntax

package.**GETLONG**(*col*, *rowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

GETSTRING Method

Returns the string value of the cell in the specified row and column.

Returned data type: STRING

Note: If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**GETSTRING**(*col*, *rowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

GETVALUE Method

Returns the value of the cell in the specified row and column.

Returned data type: STRING

Notes: When the receiving variable is of type double or decimal, DS2 converts the returned string value to a decimal.

If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**GETVALUE**(*col*, *rowIndex*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

INNERJOIN Method

Performs an inner join of two data grids and populates the target data grid with the results of the join.

Notes:
Only the rows that match the join criteria are added to the target data grid.
This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.
Support for Form 2 starts in 2023.03.

Syntax

Form 1: *package*.**INNERJOIN**(*dgLeft*, *colLeft*, *dgRight*, *colRight*);

Form 2: *package*.**INNERJOIN**(*dgLeft*, *dgRight*, *dgJoin*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

Examples

Example 1: Inner Join

Here is an example of an inner join. This example uses the source tables shown in Table 14.24 and Table 14.25 on page 1591.

In this example, the following operation is performed:

```
dataGrid_A.innerJoin(price, 'PRODUCT', quantity, 'PROD');
```

Here is the resulting data grid:

Table 14.24 *dataGrid_A*

PRODUCT	PRICE	MATCH	QUANTITY
Potatoes	1.001	l_1	44
Avocados	2.002	l_2	66
Avocados	2.002	l_2	88
Kiwis	3.003	l_3	33
Onions	4.004	l_4	99
Melons	5.005	l_5	11

Example 2: Multi-column Inner Join

Here is an example of a multi-column inner join. This example uses the source tables shown in Table 14.27 on page 1592, Table 14.28 on page 1593 and Table 14.29 on page 1593.

In this example, the following operation is performed:

```
dataGrid_B.innerJoin(cost, amount, dgJoinKeys);
```

Here is the resulting data grid:

Table 14.25 dataGrid_B

PRODUCT	TYPE	COST	MATCH	AMOUNT
Potatoes	Russet	1.001	l_1	44
Avocados	Hass	2.002	l_2	88
Avocados	Reed	2.022	l_2.2	66
Kiwis	Purple	3.033	l_3.3	33
Onions	Vidilia	4.004	l_4	99
Melons	Watermelon	5.055	l_5.5	11

INNERJOINBYFILTER Method

Performs an inner join of two data grids and populates the target data grid with the results of the join. The target column and source row criteria are specified using a column keep clause and a row filter definition.

Notes:

Only the rows that match the join criteria are added to the target data grid.

This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.

Support for this method starts in 2025.02.

Syntax

package.**INNERJOINBYFILTER**(*dgLeft*, *dgRight*, *keepColumns*, *filter* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

dgRight
specifies the variable name of the right data grid.

keepColumns
the list of columns to place in the result data grid. For more information, see "About the Keep Columns Syntax" in *SAS DS2 Programmer's Guide*.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

Examples

Example 1: Inner Join

Here is an example of an inner join. This example uses the source tables shown in Table 14.24 and Table 14.25 on page 1591.

In this example, the following operation is performed:

```
dataGrid_A.innerJoinByFilter(price, quantity, 'L.PRODUCT, L.PRICE,
L.MATCH, R.QUANTITY', 'L.PRODUCT eq R.PROD');
```

Here is the resulting data grid:

Table 14.26 *dataGrid_A*

PRODUCT	PRICE	MATCH	QUANTITY
Potatoes	1.001	l_1	44
Avocados	2.002	l_2	66
Avocados	2.002	l_2	88
Kiwis	3.003	l_3	33
Onions	4.004	l_4	99
Melons	5.005	l_5	11

In this example, an * (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid.

```
dataGrid_A.innerJoinByFilter(price, quantity, '*', 'L.PRODUCT eq
R.PROD');
```

Here is the resulting data grid:

Table 14.27 *dataGrid_A*

PRODUCT	PRICE	MATCH	PROD	QUANTITY
Potatoes	1.001	l_1	Potatoes	44
Avocados	2.002	l_2	Avocados	66
Avocados	2.002	l_2	Avocados	88
Kiwis	3.003	l_3	Kiwis	33
Onions	4.004	l_4	Onions	99
Melons	5.005	l_5	Melons	11

This example the `varlist` argument is assigned the variable called **`product`**, which is assigned the value **`Potatoes`**.

```
dataGrid_A.innerJoinByFilter(price, quantity, '*', 'L.PRODUCT eq
R.PROD & L.PRODUCT eq ?', [product]);
```

Here is the resulting data grid:

Table 14.28 *dataGrid_A*

PRODUCT	PRICE	MATCH	PROD	QUANTITY
Potatoes	1.001	l_1	Potatoes	44

Example 2: Multi-column Inner Join

Here is an example of a multi-column inner join. This example uses the source tables shown in Table 14.27 on page 1592, Table 14.28 on page 1593 and Table 14.29 on page 1593.

In this example, the following operation is performed:

```
dataGrid_B.innerJoinByFilter(cost, amount, 'L.PRODUCT, L.TYPE, L.COST,
L.MATCH, R.AMOUNT', 'L.PRODUCT eq R.PROD & L.TYPE eq R.TYPE');
```

Here is the resulting data grid:

Table 14.29 *dataGrid_B*

PRODUCT	TYPE	COST	MATCH	AMOUNT
Potatoes	Russet	1.001	l_1	44
Avocados	Hass	2.002	l_2	88

PRODUCT	TYPE	COST	MATCH	AMOUNT
Avocados	Reed	2.022	l_2.2	66
Kiwis	Purple	3.033	l_3.3	33
Onions	Vidilia	4.004	l_4	99
Melons	Watermelon	5.055	l_5.5	11

In the next example an * (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid.

```
dataGrid_B.innerJoinByFilter(cost, amount, '*', 'L.PRODUCT eq R.PROD &
L.TYPE eq R.TYPE');
```

Table 14.30 *dataGrid_B*

PRODUCT	TYPE	COST	MATCH	PROD	AMOUNT
Potatoes	Russet	1.001	l_1	Potatoes	44
Avocados	Hass	2.002	l_2	Avocados	88
Avocados	Reed	2.022	l_2.2	Avocados	66
Kiwis	Purple	3.033	l_3.3	Kiwis	33
Onions	Vidilia	4.004	l_4	Onions	99
Melons	Watermelon	5.055	l_5.5	Melons	11

INNERJOINCOUNT Method

Returns the number of rows that would be produced by an inner join operation. No data grid is affected.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.

Support for Form 2 starts in 2023.03.

Syntax

Form 1: *dgLeft*.**INNERJOINCOUNT**(*colLeft*, *dgRight*, *colRight*);

Form 2: *dgLeft*.**INNERJOINCOUNT**(*dgRight*, *dgJoin*);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

Optional Arguments

INNERJOINCOUNTBYFILTER Method

Returns the number of rows that would be produced by an inner join operation. The source row criteria is specified using a row filter definition. No data grid is affected by this operation.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.

Support for this method starts in 2025.02.

Syntax

dgLeft.**INNERJOINCOUNTBYFILTER**(*dgRight*, *filter* [, *varList*]);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

dgRight
specifies the variable name of the right data grid.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

LEFTJOIN Method

Performs a left join of two data grids and populates the target data grid with the results of the join.

Returned data type: INTEGER

Notes: All the rows in the left table are retained in the target data grid, regardless of matching join criteria.

This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.

Support for Form 2 starts in 2023.03.

Syntax

Form 1: *package*.**LEFTJOIN**(*dgLeft*, *colLeft*, *dgRight*, *colRight*);

Form 2: *package*.**LEFTJOIN**(*dgLeft*, *dgRight*, *dgJoin*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value

Examples

Example 1: Left Join

Here is an example of a left join. This example uses the source tables shown in Table 14.24 and Table 14.25 on page 1591.

In this example, the following operation is performed:

```
dataGrid_A.leftJoin(price, 'PRODUCT', quantity, 'PROD');
```

Here is the resulting data grid:

Table 14.31 *dataGrid_A*

PRODUCT	PRICE	MATCH	QUANTITY
Potatoes	1.001	l_1	44
Avocados	2.002	l_2	66
Avocados	2.002	l_2	88
Kiwis	3.003	l_3	33
Onions	4.004	l_4	99
Melons	5.005	l_5	11

PRODUCT	PRICE	MATCH	QUANTITY
Oranges	6.006	l_6	null
Tomatoes	7.007	l_7	null

Example 2: Multi-column Left Join

Here is an example of a multi-column left join. This example uses the source tables shown in Table 14.27 on page 1592, Table 14.28 on page 1593 and Table 14.29 on page 1593.

In this example, the following operation is performed:

```
dataGrid_B.leftJoin(cost, amount, dgJoinKeys);
```

Here is the resulting data grid:

Table 14.32 *dataGrid_B*

PRODUCT	TYPE	COST	MATCH	AMOUNT
Potatoes	Russet	1.001	l_1	44
Potatoes	Sweet	1.011	l_1.1	null
Avocados	Hass	2.002	l_2	88
Avocados	Reed	2.022	l_2.2	66
Kiwis	Golden	3.003	l_3	null
Kiwis	Purple	3.033	l_3.3	33
Onions	Vidalia	4.004	l_4	99
Onions	Yellow	4.044	l_4.4	null
Melons	Honey Dew	5.005	l_5	null
Melons	Watermelon	5.055	l_5.5	11
Oranges	Blood	6.006	l_6	null
Oranges	Navel	6.066	l_6.6	null
Tomatoes	Heirloom	7.007	l_7	null
Tomatoes	Beefsteak	7.077	l_7.7	null

LEFTJOINBYFILTER Method

Performs a left join of two data grids and populates the target data grid with the results of the join. The target column and source row criteria are specified using a column keep clause and a row filter definition.

Returned data type: INTEGER

Notes:
All the rows in the left table are retained in the target data grid, regardless of matching join criteria.

This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.

Support for this method starts in 2025.02.

Syntax

package.**LEFTJOINBYFILTER**(*dgLeft*, *dgRight*, *keepColumns*, *filter* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

dgRight
specifies the variable name of the right data grid.

keepColumns
the list of columns to place in the result data grid. For more information, see "About the Keep Columns Syntax" in *SAS DS2 Programmer's Guide*.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

Examples

Example 1: Left Join

Here is an example of a left join. This example uses the source tables shown in Table 14.24 and Table 14.25 on page 1591.

In this example, the following operation is performed:

```
dataGrid_A.leftJoinByFilter(price, quantity, 'L.PRODUCT, L.PRICE,
L.MATCH, R.QUANTITY', 'L.PRODUCT eq R.PROD');
```

Here is the resulting data grid:

Table 14.33 *dataGrid_A*

PRODUCT	PRICE	MATCH	QUANTITY
Potatoes	1.001	l_1	44
Avocados	2.002	l_2	66
Avocados	2.002	l_2	88
Kiwis	3.003	l_3	33
Onions	4.004	l_4	99
Melons	5.005	l_5	11
Oranges	6.006	l_6	null
Tomatoes	7.007	l_7	null

In this example an * (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid. Also, `varList` includes the variable called **`product`**, which is assigned the value **`Potatoes`**.

```
dataGrid_A.leftJoinByFilter(price, quantity, '*', 'L.PRODUCT eq R.PROD
& L.PRODUCT eq ?', [product]);
```

Here is the resulting data grid:

Table 14.34 *dataGrid_A*

PRODUCT	PRICE	MATCH	PROD	QUANTITY
Potatoes	1.001	l_1	Potatoes	44
Avocados	2.002	l_2	null	null
Kiwis	3.003	l_3	null	null

PRODUCT	PRICE	MATCH	PROD	QUANTITY
Onions	4.004	l_4	null	null
Melons	5.005	l_5	null	null
Oranges	6.006	l_6	null	null
Tomatoes	7.007	l_7	null	null

In this example, an * (asterisk) is specified for `keepColumns` which results in the inclusion of non-matching column names to the resulting data grid. However, in contrast with the previous example, a `varList` is not specified.

```
dataGrid_A.leftJoinByFilter(price, quantity, '*', 'L.PRODUCT eq
R.PROD');
```

Here is the resulting data grid:

Table 14.35 *dataGrid_A*

PRODUCT	PRICE	MATCH	PROD	QUANTITY
Potatoes	1.001	l_1	Potatoes	44
Avocados	2.002	l_2	Avocados	66
Avocados	2.002	l_2	Avocados	88
Kiwis	3.003	l_3	Kiwis	33
Onions	4.004	l_4	Onions	99
Melons	5.005	l_5	Melons	11
Oranges	6.006	l_6	null	null
Tomatoes	7.007	l_7	null	null

Example 2: Multi-column Left Join

Here is an example of a multi-column left join. This example uses the source tables shown in Table 14.27 on page 1592, Table 14.28 on page 1593 and Table 14.29 on page 1593.

In this example, the following operation is performed:

```
dataGrid_B.leftJoinByFilter(cost, amount, 'L.PRODUCT, L.TYPE, L.COST,
L.MATCH, R.AMOUNT', 'L.PRODUCT eq R.PROD & L.TYPE eq R.TYPE');
```

Here is the resulting data grid:

Table 14.36 dataGrid_B

PRODUCT	TYPE	COST	MATCH	AMOUNT
Potatoes	Russet	1.001	l_1	44
Potatoes	Sweet	1.011	l_1.1	null
Avocados	Hass	2.002	l_2	88
Avocados	Reed	2.022	l_2.2	66
Kiwis	Golden	3.003	l_3	null
Kiwis	Purple	3.033	l_3.3	33
Onions	Vidalia	4.004	l_4	99
Onions	Yellow	4.044	l_4.4	null
Melons	Honey Dew	5.005	l_5	null
Melons	Watermelon	5.055	l_5.5	11
Oranges	Blood	6.006	l_6	null
Oranges	Navel	6.066	l_6.6	null
Tomatoes	Heirloom	7.007	l_7	null
Tomatoes	Beefsteak	7.077	l_7.7	null

LEFTJOINCOUNT Method

Returns the number of rows that would be produced by a left join operation. No data grid is affected.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.
Support for Form 2 starts in 2023.03.

Syntax

Form 1: *dgLeft*.**LEFTJOINCOUNT**(*colLeft*, *dgRight*, *colRight*);

Form 2: *dgLeft*.**LEFTJOINCOUNT**(*dgRight*, *dgJoin*);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long)

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

LEFTJOINCOUNTBYFILTER Method

Returns the number of rows that would be produced by a left join operation. The source row criteria is specified using a row filter definition. No data grid is affected by this operation.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.
Support for this method starts in 2025.02.

Syntax

dgLeft.**LEFTJOINCOUNTBYFILTER**(*dgRight*, *filter*[, *varList*]);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

dgRight
specifies the variable name of the right data grid.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

NAME Method

Returns the name that is given at the declaration of the data grid instance.

Returned data type: STRING

Syntax

package.**NAME**();

Package Variable

package
specifies a name that references the datagrid package instance.

NEW Operator: Datagrid Package

Constructs an instance of a datagrid package.

Syntax

Form 1: *package*=**_NEW_DATAGRID**();

Form 2: *package*=**_NEW_DATAGRID**(*name*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

name
specifies an internal name that can be used to reference the instance.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a datagrid package variable using the DECLARE PACKAGE statement. After you declare a datagrid package variable, use the _NEW_ operator to instantiate an instance of the datagrid package and assign the new package instance to the datagrid package variable.

```
declare package datagrid dg;
dg = _new_ datagrid();
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a datagrid package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package datagrid dg();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

See Also

- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*
- "Using the Datagrid Package" in *SAS DS2 Programmer's Guide*

Statements:

- "DECLARE PACKAGE Statement: Datagrid Package" on page 1575

RIGHTJOIN Method

Performs a right join of two data grids and populates the target data grid with the results of the join.

Returned data type:	INTEGER
Notes:	All the rows in the right table are retained in the target data grid regardless of matching join criteria.

This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.

Support for Form 2 starts in 2023.03.

Syntax

Form 1: *package*.**RIGHTJOIN**(*dgLeft*, *colLeft*, *dgRight*, *colRight*);

Form 2: *package*.**RIGHTJOIN**(*dgLeft*, *dgRight*, *dgJoin*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

Examples

Example 1: Right Join

Here is an example of a right join. This example uses the source tables shown in Table 14.24 and Table 14.25 on page 1591.

In this example, the following operation is performed:

```
dataGrid_A.rightJoin(price, 'PRODUCT', quantity, 'PROD');
```

Here is the resulting data grid:

Table 14.37 dataGrid_A

PRICE	MATCH	PROD	QUANTITY
5.005	r_1	Melons	11
null	r_2	Squash	22
3.003	r_3	Kiwis	33
1.001	r_4	Potatoes	44
null	r_8	Broccoli	55
2.002	r_6	Avocados	66
null	r_8	Broccoli	77
2.002	r_5	Avocados	88
4.004	r_7	Onions	99
null	r_5	Pickles	100

In this example, an ***** (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid. Also, `varList` includes the variable called **`product`**: `product` = **`Potatoes`**.

```
dataGrid_A.rightJoin(price, quantity, '*', 'L.PRODUCT eq R.PROD &
L.PRODUCT eq ?', [product]);
```

Here is the resulting data grid:

Example 2: Multi-column Right Join

Here is an example of a multi-column right join. This example uses the source tables shown in Table 14.27 on page 1592, Table 14.28 on page 1593 and Table 14.29 on page 1593.

In this example, the following operation is performed:

```
dataGrid_B.rightJoin(cost, amount, dgJoinKeys);
```

Here is the resulting data grid:

Table 14.38 dataGrid_B

COST	MATCH	PROD	TYPE	AMOUNT
5.055	r_1	Melons	Watermelon	11
null	r_2	Squash	Butternut	22

COST	MATCH	PROD	TYPE	AMOUNT
3.033	r_3	Kiwis	Purple	33
1.001	r_4	Potatoes	Russet	44
null	r_8	Broccoli	Blue Wind	55
2.022	r_6	Avocados	Reed	66
null	r_8	Broccoli	Eastern Magic	77
2.002	r_5	Avocados	Hass	88
4.004	r_7	Onions	Vidalia	99
null	r_5	Pickles	Dill	100

RIGHTJOINBYFILTER Method

Performs a right join of two data grids and populates the target data grid with the results of the join. The target column and source row criteria are specified using a column keep clause and a row filter definition.

Returned data type: INTEGER

Notes:
- All the rows in the right table are retained in the target data grid regardless of matching join criteria.
- This method returns 0 (zero) if the join is successful and returns a nonzero value if it is not successful.
- Support for this method starts in 2025.02.

Syntax

package.**RIGHTJOINBYFILTER**(*dgLeft*, *dgRight*, *keepColumns*, *filter* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgLeft
specifies the variable name of the left data grid.

dgRight
specifies the variable name of the right data grid.

keepColumns
the list of columns to place in the result data grid. For more information, see "About the Keep Columns Syntax" in *SAS DS2 Programmer's Guide*.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

Examples

Example 1: Right Join

Here is an example of a right join. This example uses the source tables shown in Table 14.24 and Table 14.25 on page 1591.

In this example, the following operation is performed:

```
dataGrid_A.rightJoinByFilter(price, quantity, 'L.PRICE, R.MATCH,
R.PROD, R.QUANTITY', 'L.PRODUCT eq R.PROD');
```

Here is the resulting data grid:

Table 14.39 *dataGrid_A*

PRICE	MATCH	PROD	QUANTITY
5.005	r_1	Melons	11
null	r_2	Squash	22
3.003	r_3	Kiwis	33
1.001	r_4	Potatoes	44
null	r_8	Broccoli	55
2.002	r_6	Avocados	66
null	r_8	Broccoli	77

PRICE	MATCH	PROD	QUANTITY
2.002	r_5	Avocados	88
4.004	r_7	Onions	99
null	r_5	Pickles	100

In this example, an * (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid.

```
dataGrid_A.rightJoinByFilter(price, quantity, '*', 'L.PRODUCT eq
R.PROD');
```

Here is the resulting data grid:

Table 14.40 *dataGrid_A*

PRODUCT	PRICE	MATCH	PROD	QUANTITY
Melons	5.005	r_1	Melons	11
null	null	r_2	Squash	22
Kiwis	3.003	r_3	Kiwis	33
Potatoes	1.001	r_4	Potatoes	44
null	null	r_8	Broccoli	55
Avocados	2.002	r_6	Avocados	66
null	null	r_8	Broccoli	77
Avocados	2.002	r_5	Avocados	88
Onions	4.004	r_7	Onions	99
null	null	r_5	Pickles	100

In this example, an * (asterisk) is specified for `keepColumns`. This results in the inclusion of non-matching column names to the resulting data grid. Also, `varList` includes the variable called **`product`**, which is assigned the value **`Potatoes`**.

```
dataGrid_A.rightJoinByFilter(price, quantity, '*', 'L.PRODUCT eq
R.PROD & L.PRODUCT eq ?', [product]);
```

Here is the resulting data grid:

Table 14.41 dataGrid_A

PRODUCT	PRICE	MATCH	PROD	QUANTITY
null	null	r_1	Melons	11
null	null	r_2	Squash	22
null	null	r_3	Kiwis	33
Potatoes	1.001	r_4	Potatoes	44
null	null	r_8	Broccoli	55
null	null	r_6	Avocados	66
null	null	r_8	Broccoli	77
null	null	r_5	Avocados	88
null	null	r_7	Onions	99
null	null	r_5	Pickles	100

Example 2: Multi-column Right Join

Here is an example of a multi-column right join. This example uses the source tables shown in Table 14.27 on page 1592, Table 14.28 on page 1593 and Table 14.29 on page 1593.

In this example, the following operation is performed:

```
dataGrid_B.rightJoinByFilter(cost, amount, 'L.COST, R.MATCH, R.PROD,
R.TYPE, R.AMOUNT', 'L.PRODUCT eq R.PROD & L.TYPE eq R.TYPE);
```

Here is the resulting data grid:

Table 14.42 dataGrid_B

COST	MATCH	PROD	TYPE	AMOUNT
5.055	r_1	Melons	Watermelon	11
null	r_2	Squash	Butternut	22
3.033	r_3	Kiwis	Purple	33
1.001	r_4	Potatoes	Russet	44
null	r_8	Broccoli	Blue Wind	55
2.022	r_6	Avocados	Reed	66
null	r_8	Broccoli	Eastern Magic	77

COST	MATCH	PROD	TYPE	AMOUNT
2.002	r_5	Avocados	Hass	88
4.004	r_7	Onions	Vidalia	99
null	r_5	Pickles	Dill	100

RIGHTJOINCOUNT Method

Returns the number of rows that would be produced by a right join operation. No data grid is affected.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.
Support for Form 2 starts in 2023.03.

Syntax

Form 1: *dgLeft*.**RIGHTJOINCOUNT**(*colLeft*, *dgRight*, *colRight*);

Form 2: *dgLeft*.**RIGHTJOINCOUNT**(*dgRight*, *dgJoin*);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

colLeft
specifies the key column in *dgLeft*, using either a name or an index value.

dgRight
specifies the variable name of the right data grid.

colRight
specifies the key column in *dgRight*, using either a name or an index value.

dgJoin
specifies a data grid that defines a multicolumn join. *dgJoin* must have the form (string, string) or (long, long).

The first column, *dgJoin.col1*, specifies the key column in *dgLeft*, using either a name or an index value.

The second column, *dgJoin.col2*, specifies the key column in *dgRight*, using either a name or index value.

RIGHTJOINCOUNTBYFILTER Method

Returns the number of rows that would be produced by a right join operation. The source row criteria is specified using a row filter definition. No data grid is affected by this operation.

Returned data type: INTEGER

Notes: If an error occurs, this method returns -1.
Support for this method starts in 2025.02.

Syntax

dgLeft.**RIGHTJOINCOUNTBYFILTER**(*dgRight*, *filter* [, *varList*]);

Package Variable

dgLeft
specifies a name that references the datagrid package instance.

Required Arguments

dgRight
specifies the variable name of the right data grid.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

ROWADD Method

Appends the specified number of rows to the specified data grid.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the row is added and returns a nonzero value if the row is not added.

Syntax

package.**ROWADD**(*n*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

n
Specifies the number of rows to add to the data grid.

ROWCOUNT Method

Returns the number of rows in the data grid.

Returned data type: INTEGER

Syntax

package.**ROWCOUNT**();

Package Variable

package
specifies a name that references the datagrid package instance.

ROWDELETE Method

Deletes the specified rows from the specified data grid.

Returned data type: INTEGER

Notes: To delete only one row, specify its index value in *rowStartIndex*.

This method returns 0 (zero) if the rows are deleted and returns a nonzero value if the rows are not deleted.

Syntax

package.**ROWDELETE**(*rowStartIndex* <, *rowEndIndex*>);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

rowStartIndex
specifies the row number at which to begin the operation.

Optional Argument

rowEndIndex
specifies the row number at which to end the operation.

SERIALIZE Method

Returns the JSON string of the specified data grid.

Returned data type: Form 1: VARCHAR Form 2: INTEGER

Notes: A data grid accepts a JSON string with an empty array of row definitions.

Support for Form 2 signature starts in 2024.09.

If an error occurs, the Form 1 signature returns `Missing-Value` and the Form 2 signature returns a nonzero value. For more information, see "Details".

See: "About Data Grid JSON Representation" in *SAS DS2 Programmer's Guide*

Syntax

Form 1: *package*.**SERIALIZE**();

Form 2: *package*.**SERIALIZE**(*length*, *jsonString*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

length
specifies the variable that is updated with the length of the JSON string. This is an IN_OUT argument.

Data type INTEGER

jsonString
specifies the variable that is updated with the serialized datagrid in JSON format. This is an IN_OUT argument.

Data type VARCHAR

Details

The return data type is different depending on the signature that you use:

- `dg.serialize()` returns a serialized JSON string. (VARCHAR)

  Note: An empty data grid returns a null DS2 string.

- `dg.seriazlize(length, json)` returns 0 (zero) if the method is successful. If it is not successful, it returns a nonzero value. (INTEGER)

SERIALIZEDATA Method

Returns the JSON string of the row data of the specified data grid. The column metadata is not included.

Returned data type: Form 1: VARCHAR Form 2: INTEGER

Notes: If an error occurs, the Form 1 signature returns **`Missing-Value`** and the Form 2 signature returns a nonzero value. For more information, see "Details".

Support for Form 2 signature starts in 2024.09.

See: "About Data Grid JSON Representation" in *SAS DS2 Programmer's Guide*

Syntax

Form 1: *package*.**SERIALIZEDATA**();

Form 2: *package*.**SERIALIZEDATA**(*length*, *jsonString*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

length
specifies the variable that is updated with the length of the JSON string. This is an IN_OUT argument.

Data type INTEGER

jsonString
specifies the variable that is updated with the serialized datagrid in JSON format. This is an IN_OUT argument.

Data type INTEGER

Details

The return data type is different depending on the signature that you use:

- `dg.serializedata()` returns a serialized JSON string. (VARCHAR)
- `dg.seriazlizedata(length, json)` returns 0 (zero) if the method is successful. If it is not successful, it returns a nonzero value. (INTEGER)

SERIALIZEMETADATA Method

Returns the JSON string of the column metadata of the specified data grid. The row data is not included.

Returned data type: Form 1: VARCHAR Form 2: INTEGER

Notes: Support for Form 2 signature starts in 2024.09.

If an error occurs, the Form 1 signature returns **`Missing-Value`** and the Form 2 signature returns a nonzero value. For more information, see "Details".

See: "About Data Grid JSON Representation" in *SAS DS2 Programmer's Guide*

Syntax

Form 1: *package*.**SERIALIZEMETADATA**();

Form 2: *package*.**SERIALIZEMETADATA**(*length*, *jsonString*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

length
specifies the variable that is updated with the length of the JSON string. This is an IN_OUT argument.

Data type INTEGER

jsonString
specifies the variable that is updated with the serialized datagrid in JSON format. This is an IN_OUT argument.

Data type VARCHAR

Details

The return data type is different depending on the signature that you use:

- `dg.serializemetadata()` returns a serialized JSON string. (VARCHAR)
- `dg.seriazlizemetadata(length, json)` returns 0 (zero) if the method is successful. If it is not successful, it returns a nonzero value. (INTEGER)

SETALL Method

Sets all the values of a column to the specified value.

Returned data type: INTEGER

Note: This method returns the number of rows that were changed in the data grid. If an error occurs, the return value is **`Missing-Value`**.

Syntax

package.**SETALL**(*col*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

setValue
specifies the value to assign.

SETBOOL Method

Sets the specified Boolean value to the cell in the specified row and column.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**SETBOOL**(*col*, *rowIndex*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

setValue
specifies the value to assign.

SETDOUBLE Method

Sets the specified decimal value to the cell in the specified row and column.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**SETDOUBLE**(*col*, *rowIndex*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

setValue
specifies the value to assign.

SETINT Method

Sets the specified integer value to the cell in the specified row and column.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**SETINT**(*col*, *rowIndex*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

setValue
specifies the value to assign.

SETLONG Method

Sets the specified long value (64-bit integer) to the cell in the specified row and column.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**SETLONG**(*col*, *rowIndex*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

setValue
specifies the value to assign.

SETNAME Method

Renames the specified data grid.

Notes: This method returns 0 (zero) if the data grid is renamed and returns a nonzero value if an error occurs.

If you specify a null value, this method changes the data grid name to the default name `_dg`.

Syntax

package.**SETNAME**(*newName*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Argument

newName
specifies the new name.

SETSTRING Method

Sets the specified string value to the cell in the specified row and column.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**SETSTRING**(*col*, *rowIndex*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

setValue
specifies the value to assign.

SETVALUE Method

Sets the specified value to the cell in the specified row and column. This is supported only for column types of DECIMAL and STRING.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the specified value is set and returns a nonzero value if the specified value is not set.

Syntax

package.**SETVALUE**(*col*, *rowIndex*, *setValue*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

col
specifies the column, using either a name or an index value.

rowIndex
specifies the row number in the data grid.

setValue
specifies the value to assign.

SORT Method

Sorts the target data grid.

Returned data type: INTEGER

Note: This method returns 0 (zero) if the target data grid is sorted and returns a nonzero value if an error occurs.

Syntax

package.**SORT**(*sortcol*, *isAscending* | *dgSort*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

sortCol
specifies the name or index number of the column whose values are used to sort the rows in the target data grid.

isAscending
specifies whether the target data grid is sorted in ascending or descending order. Specify 0 (zero) for descending order and any other value for ascending order. If the value for sortCol is an empty character string, the function returns a null value.

dgSort
enables a data grid to be passed in to define a multicolumn sort. *dgSort* must have the form (string, num) or (num, num).

The first column, dgSort.col1, is the columnName or columnIndex.

dgSort.col2 is the value for *isAscending*.

package() is sorted by the criteria in *dgSort* from row1, then row2, through row *N*.

Example

Here is an example of a multicolumn sort.

In this example, Demographics is the target data grid and dgSort is the data grid that contains the sort criteria. Here are the contents of each data grid:

Table 14.43 *Target Data Grid: Demographics*

NAME	AGE
Charles	10
John	12
Matthew	14
Michael	16
Charles	20
John	22
Matthew	24
Michael	26
Charles	30

NAME	AGE
John	32
Matthew	34
Michael	36

Table 14.44 *Sort Criteria Data Grid: dgSort*

COL_NAME	ISASCENDING
NAME	1
AGE	0

As shown in dgSort, the NAME column is sorted first in ascending order. If there is a match, then the AGE column is used to sort in descending order.

The following operation is performed:

```
Demographics.sort(dgSort)
```

Here is the resulting data grid:

Table 14.45 *Demographics*

NAME	AGE
Charles	30
Charles	20
Charles	10
John	32
John	22
John	12
Matthew	34
Matthew	24
Matthew	14
Michael	36

NAME	AGE
Michael	26
Michael	16

SUBSET Method

Subsets the data grid to include only those rows for which comparison column and value evaluates to true.

Returned data type: INTEGER

Notes: This method returns the number of rows that have been subset. If an error occurs, this method returns -1.

Support for Form 2 starts in 2023.03.

Syntax

Form 1: *package*.**SUBSET**(*dgSource*, *cmpCol*, *operator*, *cmpValue*);

Form 2: *package*.**SUBSET**(*dgSource*, *dgCriteria*);

Package Variable

package
specifies a name that references the datagrid package instance to receive the subset results.

Required Arguments

dgSource
specifies the variable name of the source data grid.

cmpCol
specifies the column, using either a name or an index value, whose value is to be compared to *cmpValue*.

operator
specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.

cmpValue
specifies the value to compare to the value of *cmpCol*. You can specify a number, a character string enclosed in single quotation marks, the name of a variable, or the name of an expression. The value that you specify must be the same data type as *cmpCol*, or it must evaluate to the same data type as *cmpCol*.

To search for null and missing values, note the following:

- For strings, null matches only null values. Missing (an empty string or a string that contains all blank characters) matches missing values.
- For all other types, null values do not exist. If null is specified for cmpValue, it is treated as a missing value by the comparison operation.

dgCriteria
specifies a data grid to pass in that defines a multicolumn subset. *dgCriteria* must have the form (string, string, string) or (long, string, string).

- The first column, *dgCriteria.col1*, is the columnName or columnIndex.
- The second column, *dgCriteria.col2*, specifies one of the operators shown in "Comparison Operators" in *SAS DS2 Programmer's Guide*. You can specify the name of a character variable that evaluates to one of these operators, or you can specify the operator enclosed in single quotation marks.
- The third column, *dgCriteria.col3*, specifies the string representation of the value to compare against the compare column that is specified in *dgCriteria.col1*.

dgSource() is subset by the criteria in *dgCriteria* and the results are placed in *package()*. All subset criteria in *dgCriteria* must evaluate to true in order to add a row to *package*().

Examples

Here are several operation examples for the SUBSET method. These sample operations use the data shown in the Table 14.24 and Table 14.25 on page 1591 source tables.

Example 1: Subset on a Single Value

In this example, the following operation is performed:

```
dataGrid_A.subset(price, 'PRICE', 'le', 4.004);
```

Here is the resulting data grid:

Table 14.46 *dataGrid_A*

PRODUCT	PRICE	MATCH
Potatoes	1.001	l_1
Avocados	2.002	l_2

PRODUCT	PRICE	MATCH
Kiwis	3.003	l_3
Onions	4.004	l_4

Example 2: Subset on Multiple Values

The next sample operation uses the `dgCriteria` argument. Here are the contents of the **`criteria_def`** data grid:

Table 14.47 *Subset Data Grid Criteria (dgCriteria)*

Column Name	Operator	Value
MATCH	ge	r_4
QUANTITY	le	77

Here is the operation:

```
dataGrid_A.subset(quantity, criteria_def);
```

Here is the resulting data grid:

Table 14.48 *dataGrid_A*

MATCH	PROD	QUANTITY
r_4	Potatoes	44
r_8	Broccoli	55
r_6	Avocados	66
r_8	Broccoli	77

SUBSETBYFILTER Method

Subsets the data grid to include only those rows for which the row filter evaluates to true. The target column and source row criteria are specified using a column keep clause and a row filter definition.

Returned data type: INTEGER

Notes: This method returns the number of rows that have been subset. If an error occurs, this method returns -1.

Support for this method starts in 2025.02.

Syntax

package.**SUBSETBYFILTER**(*dgSource*, *keepColumns*, *filter* [, *varList*]);

Package Variable

package
specifies a name that references the datagrid package instance to receive the subset results.

Required Arguments

dgSource
specifies the variable name of the source data grid.

keepColumns
the list of columns to place in the result data grid. For more information, see "About the Keep Columns Syntax" in *SAS DS2 Programmer's Guide*.

filter
specifies the row selection criteria. For more information, see "About the Filter Syntax" in *SAS DS2 Programmer's Guide*.

Optional Arguments

varList
specifies a DS2 varlist that contains the set of DS2 variables to use to resolve the parameterized values in the filter. The parameter resolution code expects the data type of the DS2 varList variable to be consistent with the data type of the associated column.

Examples

Here are several operation examples for the SUBSETBYFILTER method. These sample operations use the data shown in the Table 14.24 and Table 14.25 on page 1591 source tables.

Example 1: Subset on a Single Value

These sample operations show different ways to perform a subset that matches a single value.

In this operation, a `filter` argument is defined:

```
dataGrid_A.subsetByFilter(price, '*', 'PRICE le 4.004');
```

In this operation, `varList` includes the variable called **d**, which is assigned the value **4.004**.

```
dataGrid_A.subsetByFilter(price, '*', 'PRICE le ?', [d]);
```

Here is the resulting data grid for each of these operations:

Table 14.49 *dataGrid_A*

PRODUCT	PRICE	MATCH
Potatoes	1.001	l_1
Avocados	2.002	l_2
Kiwis	3.003	l_3
Onions	4.004	l_4

Example 2: Subset on Multiple Values

This sample operation performs a subset that matches two values using a filter with the `'&'` logical operator:

```
dataGrid_A.subsetByFilter(quantity, '*', 'MATCH ge "r_4" & QUANTITY le
77');
```

In this sample operation, `varList` includes the variables called `match` and `count`. The variable `match` is assigned the value **r_4** and `count` is assigned the value **77**.

```
dataGrid_A.subsetByFilter(quantity, '*', 'MATCH ge ? & QUANTITY le ?',
[match count]);
```

Here is the resulting data grid for each of these operations:

Table 14.50 *dataGrid_A*

MATCH	PROD	QUANTITY
r_4	Potatoes	44
r_8	Broccoli	55
r_6	Avocados	66
r_8	Broccoli	77

TOPN Method

Sorts the target data grid in descending order, by the specified column, and then truncates it to the first *N* rows.

Returned data type: INTEGER

Note: This method returns the number rows in the resulting target data grid. If an error occurs, this method returns -1.

Syntax

package.**TOPN** (*dgSource*, *col*, *N*);

Package Variable

package
specifies a name that references the datagrid package instance.

Required Arguments

dgSource
specifies the variable name of the source data grid.

col
specifies the column, using either a name or an index value.

N
specifies the maximum number of rows to return.

VERSION Method

Returns the version of the data grid interface.

Returned data type: STRING

Syntax

package.**VERSION**();

Package Variable

package
specifies a name that references the datagrid package instance.

15

DS2 FCMP Package Methods, Operators, and Statements

Dictionary

DECLARE PACKAGE Statement: FCMP Package

Creates a package variable and gives you the option to create an instance of the FCMP package.

Category: Local

Restriction: This statement is not supported on the CAS server.

Requirement: The PACKAGE statement is required before you use the DECLARE PACKAGE statement.

Note: DS2 supports PROC FCMP OUTARGS statement arguments with code blocks from the PROC FCMP SUBROUTINE statement. DS2 does not support OUTARGS statement arguments with code blocks from the PROC FCMP FUNCTION statement.

Syntax

DECLARE PACKAGE *fcmp-package-name variable* ( );

Required Arguments

fcmp-package-name
specifies the name of the FCMP package.

Requirement The package name must match the name of a package created in a PACKAGE statement, or an error will occur.

See "PACKAGE Statement" on page 1406

variable
specifies a name that can reference an instance of the package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use an FCMP package to support calls to functions and subroutines that are available or are created with the FCMP procedure. The FCMP package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

You declare an FCMP package by using the DECLARE PACKAGE statement. This associates an FCMP package with an FCMP name. After you declare the new FCMP package, you can call the functions and subroutines that are created with the FCMP procedure.

There are two ways to construct an instance of an FCMP package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package fcmp pharma;
pharma = _new_ fcmp();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package fcmp pharma();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

For more information about FCMP packages, see "Using the FCMP Package" in *SAS DS2 Programmer's Guide*.

Examples

Example 1: Using FCMP OUTARGS Parameters

The following example creates FCMP subroutine named **package1** that uses OUTARGS parameters. The FCMP procedure's OUTARGS parameter is treated as an IN_OUT parameter in the METHOD statement.

```
libname base '.';
proc fcmp outlib = base.fcmpsubs.package1;
   subroutine swapper(a,b);
      outargs a,b;
      t1 = b; b = a; a = t1;
   endsub;
run;
quit;

proc ds2;
   package pkg / overwrite=yes language='fcmp' table='base.fcmpsubs';
run;

data _null_;
   dcl package pkg p();
   method init();
      dcl double x y;
      x=10;
      y=42;
      put 'before:' x= y=;
      p.swapper(x,y);
      put 'after:' x= y=;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
before: x=10 y=42
after: x=42 y=10
```

Example 2: FCMP Package Using DOUBLE Arguments

This example walks through creation of a square routine in FCMP and using that routine from a DS2 program. The current directory is used as the "library" of FCMP packages.

```
libname base '.';

* fcmp defines a function, square;
proc fcmp outlib = base.fcmpsubs.package1;
   function square(a);
      return (a*a);
   endsub;
run;
quit;
```

```
* define the ds2 package thru which the fcmp functions will be called;
proc ds2;
   package pkg /overwrite=yes language='fcmp' table='base.fcmpsubs';
run;

* demonstration of calling fcmp thru the ds2 wrapper package;
data _null_;
   dcl package pkg p();
   dcl double a b;
   method init();
      do a = 10 to 20;
         b=p.square(a);
         put a= b=;
      end;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
a=10 b=100
a=11 b=121
a=12 b=144
a=13 b=169
a=14 b=196
a=15 b=225
a=16 b=256
a=17 b=289
a=18 b=324
a=19 b=361
a=20 b=400
```

Example 3: FCMP Package with Character Arguments

```
libname base '.';

proc fcmp outlib = base.fcmpsubs.package1;
   function f(a $) $ 10;
      return (trim(a) !! trim(a));
   endsub;
run;

proc ds2;
   package pkg /overwrite=yes language='fcmp' table='base.fcmpsubs';
run;

data _null_;
   dcl package pkg p();
   method runone(double arg, double expected);
      dcl double actual;
      actual=p.f(arg);
      if (actual ~= expected) then put 'ERROR:' arg= expected= actual=;
   end;
   method init();
      runone(5, 55);
      runone(345, 345345);
      runone(10, 1010);
```

```
      runone(4.2, .);     * can't convert back to double w/ two '.' chars;
      runone(., .);
   end;
enddata;
run;
quit;
```

Operators:

- "_NEW_ Operator: FCMP Package" on page 1656

Statements:

- "PACKAGE Statement" on page 1406

DELETE Method: FCMP Package

Deletes an FCMP package.

Restriction: This method is not supported on the CAS server.

Note: The DELETE method is not required. When no FCMP package variables reference an FCMP package instance, the package instance is automatically deleted.

Syntax

package.**DELETE**( );

Required Argument

package
specifies the name of the FCMP package variable.

Details

When you no longer need the FCMP package, delete it by using the DELETE method. If you attempt to use an FCMP package after you delete it, an error will be written to the log.

See Also

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

NEW Operator: FCMP Package

Constructs an instance of an FCMP package.

Restriction: This operator is not supported on the CAS server.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_** *fcmp-package-name*( );

Required Arguments

package-variable
specifies a name that can reference an instance of the package.

fcmp-package-name
specifies the name of the package.

Requirement *fcmp-package-name* must be a predefined FCMP package created with a PACKAGE statement.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You create an FCMP package by using the PACKAGE statement then declare and instantiate the FCMP package by using the DECLARE PACKAGE statement. This associates an FCMP package with an FCMP package variable name. After you declare the new FCMP package, you can call the functions and subroutines that are created with the FCMP procedure.

There are two ways to construct an instance of an FCMP package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package pharma pkg;
pkg = _new_ pharma();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package pharma pkg();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

DS2 Hash and Hash Iterator Package Attributes, Methods, Operators, and Statements

Dictionary

ADD Method: Hash Package

Adds key values, data values, or both to the hash package.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**ADD**();

Form 2: *package*.**ADD**(\[*keys*\], \[*data*\]);

Form 3: *package*.**ADD**(\[*keys*\]);

Required Argument

package
specifies an instance of the hash package variable.

Optional Arguments

[*keys*]
specifies the key values by using a variable list.

Restriction: If you specify only keys, the ADD method works only for key-only hash packages.

See: "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the variables into which to add the hash data.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

You can store key and data values in the hash package using the ADD method.

There are two ways to pass keys and data values to the ADD method:

- implicit variable method (Form 1)

  The key and data variables are implied in the ADD method invocation and do not have to be specified.

- variable list method (Forms 2 and 3)

  The specified key and data variables are passed explicitly to the ADD method. If the hash package contains only keys, use Form 3.

Note:

- If you add a key that is already in the hash package, then the ADD method returns a nonzero value to indicate that the key is already in the hash package. Use the REPLACE method to replace the data that is associated with the specified key with new data. However, if you set the DUPLICATE constructor parameter or method to `ADD` when you create the hash package, the ADD method returns a zero.
- If you do not specify the data variables with the DEFINEDATA method, the data variables are automatically assumed to be same as the keys.
- The ADD method does not set the value of the data variable to the value of the data item. It sets only the value in the hash package.

Examples

Example 1: Using the Implicit Variable Method

The following example uses the implicit variable method to define the key and data item.

```
data _null_;
   declare char(20) d;
   declare char(20) k;
   declare double rc;
   declare package hash h(4);
   method init();
      /* Define constant value for key and data */
      rc = h.defineKey ('k');
```

```
      rc = h.defineData ('d');
      rc = h.defineDone ();
      /* Define constant value for key and data */
      k='Homer';
      d ='Odyssey';
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add();
      /* Define constant value for key and data */
      k='Joyce';
      d='Ulysses';
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add();
   end;
enddata;
run;
```

Example 2: Adding Key and Data Values Using the Variable List Method

The following example uses the implicit variable method to define the key and data item.

```
data _null_;
   declare char(20) d;
   declare char(20) k;
   declare double rc;
   method init();
      declare package hash h([k], [d]);
      /* Define constant value for key and data */
      k='Homer';
      d ='Odyssey';
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add([k], [d]);
      /* Define constant value for key and data */
      k='Joyce';
      d='Ulysses';
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add([k], [d]);
      h.output('hashdata2');
   end;
enddata;
run;
```

Example 3: Using the ADD and FIND Methods

The following example uses the ADD method to store the data in the hash package and associate the data with the key. The FIND method is then used to retrieve the data that is associated with the key value 'Homer'.

```
data _null_;
   declare char(20) d;
   declare char(20) k;
   declare double rc;
   method init();
      declare package hash h([k], [d], 4);
      /* Define constant value for key and data */
```

```
      k='Homer';
      put k=;
      d='Odyssey';
      put d=;
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add([k], [d]);
      /* Define constant value for key and data */
      k='Joyce';
      d='Ulysses';
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add([k], [d]);
      k='Homer';
      /* Use the FIND method to retrieve the data associated with 'Homer' key */
      if (h.find([k],[d]) = 0) then
     put d=;
     else
     put 'Key Homer not found.';
   end;
enddata;
run;
```

The FIND method assigns the data value 'Odyssey' to the variable D. 'Odyssey' is associated with the key value `Homer'.

The following lines are written to the SAS log:

```
k=Homer
d=Odyssey
d=Odyssey
```

CHECK Method

Checks whether the specified key is stored in the hash package.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**CHECK**( );

Form 2: *package*.**CHECK**(\[*keys*\]);

Required Argument

package
specifies an instance of the hash package variable.

Optional Argument

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

You use the CHECK method to determine whether a key exists in the hash table but the data variable is not updated. The CHECK method returns a zero value if the key is found in the hash table and a nonzero value if the key is not found.

There are two ways to pass keys and data variables to the CHECK method:

- implicit variable method (Form 1)

  The key variables are implied in the CHECK method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified key variables are passed explicitly to the CHECK method.

Comparisons

The CHECK method returns only a value that indicates whether the key is in the hash package. The data variable that is associated with the key is not updated. The FIND method also returns a value that indicates whether the key is in the hash package. However, if the key is in the hash package, then the FIND method also sets the data variable to the value of the data item so that it is available for use after the method call.

Example

In the following example, the CHECK method is used to determine whether the data is associated with the key value 'Homer'.

```
data _null_;
   declare char(20) d;
   declare char(20) k;
   declare double rc;
   method init();
      declare package hash h([k], [d]);
      /* Define constant value for key and data */
      k='Homer';
      put k=;
      d='Odyssey';
      put d=;
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add([k], [d]);
      /* Define constant value for key and data */
      k='Joyce';
      d='Ulysses';
      /* Use the ADD method to add the key and data to the hash package */
      rc = h.add([k], [d]);
      k='Homer';
      /* Use the CHECK method to verify the data associated with 'Homer' key */
      if (h.check([k]) = 0) then
         put 'Key Homer is found.';
      else
          put 'Key Homer not found.';
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
k=Homer
d=Odyssey
Key Homer is found
```

CLEAR Method

Removes all items from a hash package without deleting the hash package instance.

Applies to: Hash package

Syntax

package.**CLEAR**( );

Required Argument

package
specifies an instance of the hash package variable.

Details

The CLEAR method removes the items from within the hash package but leaves the hash package instance so that it can be reused. To remove a hash package completely, use the DELETE method.

To clear all items from the hash package MYHASH, use the following code:

```
rc = myhash.clear();
```

See Also

Methods:

- "DELETE Method: Hash, and Hash Iterator Package" on page 1685

DATA Method

Specifies the data variables to be stored in the hash package by using a variable list.

Applies to: Hash package

Notes: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

All variables that are passed to a hash instance must be global variables.

Syntax

package.**DATA**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*data*]
specifies the name of the data variables by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You use a variable list to specify the data variables for a hash package using the DATA method. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

Note: Alternatively, you could use the DEFINEDATA method or constructors in the DECLARE PACKAGE statement to specify the data variables.

Keys and data consist of any number of character or numeric variables.

Example

This example creates a hash package that contains two data variables and one key variable. The output is sorted in descending order.

```
data _null_;
   dcl double x;
   dcl double rc;
   dcl date d;
   /* The output will be in descending order. */
   dcl package hash h(8, '', 'descending', '', '');
   dcl package hiter hi('h');

   method init();
      rc = h.keys([d]);
      rc = h.data([d]);
      rc = h.data([x]);
      rc = h.definedone();
      d = date '1929-08-24'; x = 1; h.add();
      d = date '1930-09-25'; x = 2; h.add();
      d = date '1930-10-26'; x = 3; h.add();
      d = date '1930-10-27'; x = 4; h.add();
      d = date '1933-12-28'; x = 5; h.add();
      d = date '1999-12-01'; x = 999;
      do while (hi.next() = 0);
         put d= x=;
         d = date '1999-12-01'; x = 999;
      end;
   end;
enddata;
```

```
run;
```

The following lines are written to the SAS log.

```
d=1933-12-28 x=5
d=1930-10-27 x=4
d=1930-10-26 x=3
d=1930-09-25 x=2
d=1929-08-24 x=1
```

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

DATASET Method

Specifies the name of a table to load into the hash package.

Applies to: Hash package

Restriction: This method is not supported on the CAS server.

Notes: Braces in the syntax convention indicate a syntax grouping. The escape character (\ ) before a brace indicates that the brace is required in the syntax. *sql-text* must be enclosed in braces ({ }).

All variables that are passed to a hash instance must be global variables.

Syntax

package.**DATASET**(['*data-source*'] | '\{*sql-text*\}');

Required Arguments

package
specifies an instance of the hash package variable.

***data-source* | {*sql-text*}**
specifies the name of a table to load into the hash package either as a data source or a FedSQL query..

data-source
specifies the name of a table.

Tip The name of the table can be a string literal or a character variable. If a literal is used, the table name must be enclosed in single quotation marks.

'{*sql-text*}'
is a character string containing any valid FedSQL code that resolves to a set of table rows.

Restriction This argument is not supported on the CAS server.

Requirement The FedSQL query must be enclosed in braces ({ }).

Note The FedSQL query is specified in the following form: {`SELECT <select-list> FROM <table-specification>;`}. For more information, see the SELECT statement in the *SAS FedSQL Language Reference*.

Details

You can specify the table to load into the hash package by using the DATASET method.

Note: Alternatively, you can use the *datasource* parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify the table.

See Also

- "Storing and Retrieving Data" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: Hash Package" on page 1707

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

DECLARE PACKAGE Statement: Hash Package

Creates a package variable and gives you the option of creating an instance of the hash package.

Category: Local

Notes: Braces in the syntax convention indicate a syntax grouping. The escape character (\ ) before a brace indicates that the brace is required in the syntax. *sql-text* must be enclosed in braces ({ }).

The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

All variables that are passed to a hash instance must be global variables.

Tip: The PACKAGE statement is not required for a hash package.

Syntax

Form 1: **DECLARE PACKAGE HASH** *variable* ( );

Form 2: **DECLARE PACKAGE HASH** *variable* (*hashexp*, {'*datasource*' | '\{*sql-text*\}'}, '*ordered*', '*duplicate* ', '*suminc*', '*multidata*');

Form 3: **DECLARE PACKAGE HASH** *variable* (\[*keys*\], \[*data*\], [*hashexp*, {'*datasource*' | '\{*sql-text*\}'}, '*ordered*', '*duplicate* ', '*suminc*', '*multidata*']);

Form 4: **DECLARE PACKAGE HASH** *variable* (\[*keys*\], [*hashexp*, {'*datasource*' | '\{*sql-text*\}'}, '*ordered*', '*duplicate* ', '*suminc*', '*multidata*']);

Arguments

variable
specifies a variable that can reference an instance of the hash package.

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the data variables by using a variable list and associates them with the specified keys.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

hashexp
is the hash package's internal table size, where the size of the hash table is 2^n.

The value of hashexp is used as a power-of-two exponent to create the hash table size. For example, a value of 4 for hashexp equates to a hash table size of

2^4, or 16. The maximum value for hashexp is 16, which equates to a hash table size of 2^{16}.

The hash table size is not equal to the number of items that can be stored. Think of the hash table as an array of containers. A hash table size of 16 would have 16 containers. Each container can hold an infinite number of items. The efficiency of the hash tables lies in the ability of the hash function to map items to and retrieve items from the containers.

In order to maximize the efficiency of the hash package lookup routines, you should set the hash table size according to the amount of data in the hash package. Try different hashexp values until you get the best result. For example, if the hash package contains one million items, a hash table size of 16 (hashexp = 4) would not be very efficient. A hash table size of 512 or 1024 (hashexp = 9 or 10) would result in better performance.

Range 0–20

Requirement A value for *hashexp* must be entered. If a value less than 0 is entered, then a default value of 8, which equates to a hash table size of 2^8 or 256, is used. If a value greater than 20 is entered, then a default value of 20 is used.

Data type INTEGER

'datasource'
is the name of a table to load into the hash package.

The name of the table can be a literal or a character variable. The table name must be enclosed in single quotation marks.

Restriction If the datasource argument is not null, then the DECLARE PACKAGE statement is not supported on the CAS server.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *datasource* must be entered. If the place holder is entered, then the hash is not loaded from a data source.

{sql-text}
is any valid FedSQL SELECT statement that resolves to a set of table rows.

Restriction This argument is not supported on the CAS server.

Requirement The FedSQL query must be enclosed in braces ({ }).

Note The FedSQL query is specified in the following form: {`SELECT <select-list> FROM <table-specification>;`}. For more information, see the SELECT statement in the *SAS FedSQL Language Reference*.

'ordered'
specifies whether or how the data is returned in key-value order if you use the hash package with a hash iterator package or if you use the hash package OUTPUT method.

ordered can be one of the following values:

'ASCENDING'
Data is returned in ascending key-value order. Specifying `**ASCENDING**' is the same as specifying '**YES**'.

Alias 'A'

'DESCENDING'
Data is returned in descending key-value order.

Alias 'D'

'YES'
Data is returned in ascending key-value order. Specifying '**YES**' is the same as specifying '**ASCENDING**'.

'NO'
Data is returned in an undefined order.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *ordered* must be entered. If the place holder is entered, then a default ordering of 'NO' is used.

'duplicate'
determines whether to ignore duplicate keys when loading a table into the hash package. The default is to store the first key and ignore all subsequent duplicates.

duplicate can be one of the following values:

'REPLACE'
stores the last duplicate key record.

'ERROR'
reports an error to the log if a duplicate key is found.

'ADD'
stores the first key record found and not any of the duplicates.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *duplicate* must be entered. If the place holder is entered, then a default of 'ADD' is used.

See "Example 3: Using the Duplicate Parameter with a Hash Package" on page 1676

'suminc'
specifies a variable that maintains a summary count of hash package keys.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *suminc* must be entered.

Data type INTEGER

Note This variable holds the sum increment–that is, how much to add to the key summary for each reference to the key. The *suminc* value treats a missing or null value as zero, like the SUM function. For

example, a key summary changes using the current value of the variable.

'multidata'
specifies whether multiple data items are allowed for each key.

multidata can be one of the following values:

'YES'
allows multiple data items for each key

Alias 'Y' or 'MULTIDATA'

'NO'
allows only one data items for each key

Alias 'N' or 'SINGLEDATA'

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *multidata* must be entered. If the place holder is entered, then a default of 'NO' is used.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

A particular hash package instance is defined by a set of key variables, a set of data variables, and optional initialization data. A hash package instance can be defined either fully at construction or at construction and through a subsequent series of method calls. If key variables and data variables are specified when the hash package instance is constructed (Forms 3 and 4), then the hash instance is constructed as fully defined. If key variables and data variables are not provided when the hash package instance is constructed (Form 2), then additional definition of the hash instance can be specified with a subsequent series of method calls followed by a single DEFINEDONE method call. The DEFINEDONE method indicates that specification of key variables, data variables, and other initialization data is complete. A hash package instance is not constructed if no variables or initialization data is provided (Form 1). In this instance, the hash instance is constructed with the _NEW_ operator or additional method calls followed by a single DEFINEDONE method call.

In the following example, hash **h1** and hash **h2** have equivalent definition. Hash **h1** is fully defined when the hash is constructed because key and data variables are provided as constructor arguments. Hash **h2** is only partially defined when the hash is constructed, and the hash definition is completed through a series of method calls followed by a single DEFINEDONE method call.

```
declare package hash h1([key1], [data1 data2 data3],
    0, 'testdata', '', '', '', 'multidata');
declare package hash h2();

h2.keys([key1]);
```

```
h2.data([data1 data2 data3]);
h2.dataset('testdata');
h2.multidata();
h2.defineDone();
```

A DECLARE PACKAGE statement can create a hash package variable that is a null package reference. The hash package variable can then be set to reference a hash package instance constructed by a subsequent call of the _NEW_ operator.

```
declare package hash hashgnp;
hashgnp = _new_ hash(10, 'testpkg', 'yes');
```

(Optional) A DECLARE PACKAGE statement can both create the hash package variable and construct the hash package instance.

```
declare package hash hashgnp(10, 'testpkg', 'yes');
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

For more information about the hash package, see "Using the Hash Package" in *SAS DS2 Programmer's Guide*.

Examples

Example 1: Storing and Retrieving Data with a Hash Package

The following example declares a hash package named H that will store several key/value pairs and uses an iterator to write the keys in sorted order.

```
data _null_;
    dcl double x;
    dcl date d;
/* The output will be in descending order. */
    dcl package hash h(8, '', 'descending', '', '');
    dcl package hiter hi('h');
    method init();
      rc = h.defineKey('d');
      rc = h.defineData('d');
      rc = h.defineData('x');
      rc = h.defineDone();

      d = date '1929-08-24'; x = 1; h.add();
      d = date '1930-09-25'; x = 2; h.add();
      d = date '1930-10-26'; x = 3; h.add();
      d = date '1930-10-27'; x = 4; h.add();
      d = date '1933-12-28'; x = 5; h.add();

      d = date '1999-12-01'; x = 999;
      do while (hi.next() = 0);
        put d= x=;
        d = date '1999-12-01'; x = 999;
      end;
    end;
```

```
    enddata;
```

The following lines are written to the SAS log:

```
d=1933-12-28 x=5
d=1930-10-27 x=4
d=1930-10-26 x=3
d=1930-09-25 x=2
d=1929-08-24 x=1
```

Example 2: Loading a Table into a Hash Package

Assume that the table SMALL contains two numeric variables K (key) and S (data) and another table, LARGE, contains a corresponding key variable K. The following code loads the SMALL table into the hash package, and then searches the hash package for key matches on the variable K from the LARGE table.

```
/* create small table */
data small(overwrite=yes);
  dcl char(8) k s;
  method init();
    dcl integer i;
    do i = 1 to 10;
      k = put(i, BEST8.);
      s = put(2*i, BEST8.);
      output;
    end;
  end;
enddata;
run;
/* create large table */
data large(overwrite=yes);
  dcl char(8) k;
  method init();
    dcl integer i;
    do i = -20 to 20;
      k = put(i, BEST8.);
      output;
    end;
  end;
enddata;
run;

/*load SMALL table into the hash package */
data myhash(overwrite=yes);
  declare char(8) k;
  declare char(8) s;
  declare package hash h(8,'small');

 /* define SMALL table variable K as key and S as value */

  method init();
    rc = h.defineKey('k');
    rc = h.defineData('s');
    rc = h.defineDone();
  end;
```

```
/* use the SET statement to iterate over the LARGE table using */
/* keys in the LARGE table to match keys in the hash package */

  method run();
    set large;
    if (h.find() = 0) then output;
  end;

enddata;
run;
```

Example 3: Using the Duplicate Parameter with a Hash Package

Here is an example of using the ADD, REPLACE, and ERROR options with the DUPLICATE parameter.

```
data dups(overwrite=yes);
   dcl double x y;
   method init();
      do x = 1 to 5;
         y = 2*x;
         output;
      end;
      x = 3; y = 99; output;
      x = 4; y = 100; output;
   end;
enddata;
run;

data _null_;
   dcl double x y;
   dcl int rc1 rc2 rc3 rc4;
   dcl package hash h(8, 'dups', 'yes');
   dcl package hiter hi;
   method init();
      rc = h.defineKey('x');
      rc = h.defineData('x');
      rc = h.defineData('y');
      rc = h.defineDone();

      hi = _new_ hiter('h');
        do while (hi.next() = 0);
        put x= y=;
        end;
      put;
   end;
enddata;
run;

data _null_;
   dcl double x y;
   dcl int rc1 rc2 rc3 rc4;
   dcl package hash h(8, 'dups', 'yes', 'add');
   dcl package hiter hi;
   method init();
      rc = h.defineKey('x');
```

```
      rc = h.defineData('x');
      rc = h.defineData('y');
      rc = h.defineDone();

      hi = _new_ hiter('h');
         do while (hi.next() = 0);
           put x= y=;
         end;
      put;
   end;
enddata;
run;

data _null_;
   dcl double x y;
   dcl int rc1 rc2 rc3 rc4;
   dcl package hash h(8, 'dups', 'yes', 'replace');
   dcl package hiter hi;
   method init();
      rc = h.defineKey('x');
      rc = h.defineData('x');
      rc = h.defineData('y');
      rc = h.defineDone();

      hi = _new_ hiter('h');
        do while (hi.next() = 0);
        put x= y=;
        end;
      put;
   end;
enddata;
run;

data _null_;
   dcl double x y;
   dcl int rc1 rc2 rc3 rc4;
   dcl package hash h(8, 'dups', 'yes', 'error');
   dcl package hiter hi;
   method init();
      rc = h.defineKey('x');
      rc = h.defineData('x');
      rc = h.defineData('y');
      rc = h.defineDone();

      hi = _new_ hiter('h');
        do while (hi.next() = 0);
           put x= y=;
        end;
      put;
   end;
enddata;
run;
```

The following lines are written to the SAS log when using the ADD option:

```
x=1 y=2
x=2 y=4
x=3 y=6
x=4 y=8
x=5 y=10

NOTE: Execution succeeded. No rows affected.
```

The following lines are written to the SAS log when using the REPLACE option:

```
x=1 y=2
x=2 y=4
x=3 y=99
x=4 y=100
x=5 y=10

NOTE: Execution succeeded. No rows affected.
```

When using the ERROR option, an error message is written to the SAS log:

```
ERROR: Line 174: Error reported by DS2 package d2hash:
ERROR: Line 174: Duplicate key found when loading hash object from data source dups.
ERROR: Line 174: Error reported by DS2 package d2hash:
ERROR: Line 174: Hash data source load failed.
ERROR: Line 174: Fatal run-time error.
ERROR: General error
```

Example 4: Using the ORDERED Parameter with a Hash Package

The following example sets an ascending order for the hash package H and a descending order for the hash package H2.

```
data _null_;
    dcl double x y;
    dcl package hash h(8, '', 'ascending');
    dcl package hash h2(8, '', 'descending');
    dcl package hiter hi('h');
    dcl package hiter hi2('h2');
    method init();
      rc = h.defineKey('x');
      rc = h.defineKey('y');
      rc = h.defineDone();

      rc = h2.defineKey('y');
      rc = h2.defineKey('x');
      rc = h2.defineDone();

      do x = 1 to 10;
        y = 2 * x;
        rc = h.add();
        rc = h2.add();
      end;

      hi.first(); put y=;
      do while (hi.next() = 0);
        put y=;
```

```
      end;
      put;

      hi2.first(); put x=;
      do while (hi2.next() = 0);
        put x=;
      end;
    end;
  enddata;
run;
```

Statements:

- "DECLARE PACKAGE Statement: Hash Iterator Package" on page 1679

DECLARE PACKAGE Statement: Hash Iterator Package

Creates a hash iterator package variable and gives you the option of creating an instance of the hash iterator package.

Category: Local

Tip: The PACKAGE statement is not required for a hash iterator package.

Syntax

DECLARE PACKAGE HITER *variable* [(*'hash-name'* | *hash-package-instance*)];

Required Argument

variable
specifies a name that can reference an instance of the hash iterator package variable.

Optional Arguments

'hash-name'
specifies the name of the hash package with which the hash iterator is associated.

hash-package-instance
specifies the instance of the hash package with which the hash iterator is associated.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use the hash and hash iterator packages to quickly and efficiently store, search, and retrieve data based on unique lookup keys. The hash and hash iterator packages are predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

You declare a hash iterator package by using the DECLARE PACKAGE statement. This associates a hash iterator package with a hash and hash iterator name.

Note: You must declare and instantiate a hash package before you create a hash iterator package.

There are two ways to construct an instance of a hash iterator package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package hiter myhiter;
myhiter = _new_ hiter('h');
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package hiter myiter('h');
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

DEFINEDATA Method

Defines data variables for the hash package using implicit variables.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**DEFINEDATA**('*data*');

Required Arguments

package
specifies an instance of the hash package variable.

'data'
specifies the name of the data variable.

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You call the DEFINEDATA method for each data variable that you create. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

Note: Alternatively, you could use the DATA variable list method or constructors in the DECLARE PACKAGE statement to specify the data variables.

Keys and data consist of any number of character or numeric variables.

Example

This example creates a hash package that contains two data variables and one key variable. The output is sorted in descending order.

```
data _null_;
   dcl double x;
   dcl double rc;
   dcl date d;
   /* The output will be in descending order. */
   dcl package hash h(8, '', 'descending', '', '');
   dcl package hiter hi('h');

   method init();
      rc = h.definekey('d');
      rc = h.definedata('d');
      rc = h.definedata('x');
      rc = h.defineDone();
      d = date '1929-08-24'; x = 1; h.add();
      d = date '1930-09-25'; x = 2; h.add();
      d = date '1930-10-26'; x = 3; h.add();
      d = date '1930-10-27'; x = 4; h.add();
      d = date '1933-12-28'; x = 5; h.add();
      d = date '1999-12-01'; x = 999;
      do while (hi.next() = 0);
         put d= x=;
         d = date '1999-12-01'; x = 999;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
d=1933-12-28 x=5
d=1930-10-27 x=4
d=1930-10-26 x=3
d=1930-09-25 x=2
d=1929-08-24 x=1
```

Methods:

- "DATA Method" on page 1666
- "DEFINEDONE Method" on page 1683

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

DEFINEDONE Method

Indicates that all key and data definitions are complete.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**DEFINEDONE**( );

Required Argument

package
specifies an instance of the hash package variable.

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You can define the key and data variables in one of three ways.

- Use the implicit variable methods DEFINEDATA and DEFINEKEY.
- Use the variable list methods DATA and KEYS.
- Use key and data variable lists as constructors in the DECLARE PACKAGE statement.

If the hash package is not completely defined using constructors in the DECLARE PACKAGE statement, you must call the DEFINEDONE method to complete initialization of the hash package.

Example

The following example creates a hash package, defines the key and data variables, and completes the initialization of the hash package:

```
/* definedone with definedata method */
declare hash h(h);
 rc = h.defineKey('k');
 rc = h.defineData('d');
 rc = h.defineDone();
```

```
/* same package using definedone with data method */
declare hash h;
rc=h.keys([k]);
rc=h.data([d]);
rc=definedone();
```

Methods:

- "DEFINEDATA Method" on page 1681
- "DEFINEKEY Method" on page 1684

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

DEFINEKEY Method

Defines key variables for the hash package using implicit variables.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**DEFINEKEY**('*key*');

Required Arguments

package
specifies an instance of the hash package variable.

'key'
specifies the name of the key variable.

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You call the DEFINEKEY method for each key variable that you create. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

Note: Alternatively, you could use the KEYS variable list method or constructors in the DECLARE PACKAGE statement to specify the key variables.

Keys and data consist of any number of character or numeric variables.

Example

The following example creates a hash package and defines the key and data variables:

```
declare hash h();
rc = h.definekey('k');
rc = h.definedata('d');
rc = h.definedone();
end;
```

DELETE Method: Hash, and Hash Iterator Package

Deletes a hash or hash iterator package.

Applies to: Hash and hash iterator packages

Note: The DELETE method is not required. When a hash or hash iterator package variables reference a hash or hash iterator package instance, the package instance is automatically deleted.

Syntax

package.**DELETE**( );

Required Argument

package
specifies an instance of the hash or hash iterator package variable.

Details

When you no longer need the hash or hash iterator package, delete it by using the DELETE method. If you attempt to use a hash or hash iterator package after you delete it, an error will be written to the log.

If you want to delete all the items from within a hash package and save the hash package to use again, use the CLEAR method.

See Also

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

DUPLICATE Method

Determines whether to ignore duplicate keys when loading a table into the hash package. The default is to store the first key and ignore all subsequent duplicates.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**DUPLICATE**('*option*');

Required Arguments

package
specifies an instance of the hash package variable.

'option'
option can be one of the following values:

'REPLACE'
stores the last duplicate key record.

'ERROR'
reports an error to the log if a duplicate key is found.

'ADD'
stores the first key record found and not any of the duplicates.

Default ADD

Details

By default, all of the keys in a hash package are unique. This means one set of data variables exists for each key. In some situations, you might want to have duplicate keys in the hash package, that is, associate more than one set of data variables with a key.

If the table contains duplicate keys, by default, the first instance is stored in the hash package and subsequent instances are ignored. To store the last instance in the hash package, use the DUPLICATE method. The DUPLICATE method also writes an error to the SAS log if there is a duplicate key.

However, the hash package allows storage of multiple values for each key if you use the MULTIDATA parameter or method. The hash package keeps the multiple values in a list that is associated with the key. This list can be traversed and manipulated by using several methods such as HAS_NEXT or FIND_NEXT.

Note: Alternatively, you can use the *duplicate* parameter as a constructor in the DECLARE PACKAGE statement or the _NEW_ operator to specify duplicate keys.

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

FIND Method

Determines whether the specified key is stored in the hash package.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**FIND**( );

Form 2: *package*.**FIND**(\[*keys*\], \[*data*\]);

Form 3: *package*.**FIND**(\[*keys*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key values by using a variable list.

Restriction If you specify only keys, the FIND method works only for key-only hash packages.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the variables into which to copy the hash data.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

You use the key variable values to determine whether a key exists in the hash table. If the key exists, the data values are copied into the data variables. The FIND

method returns a zero value if the key is found in the hash table and a nonzero value if the key is not found.

There are two ways to pass key and data variables to the FIND method:

- implicit variable method (Form 1)

  The key and data variables are implied in the FIND method invocation and do not have to be specified.

- variable list method (Forms 2 and 3)

  The specified key and data variables are passed explicitly to the FIND method. If the hash package contains only keys, use Form 3.

Comparisons

The FIND method returns a value that indicates whether the key is in the hash package. If the key is in the hash package, then the FIND method also sets the data variable to the value of the data item so that it is available for use after the method call. The CHECK method returns only a value that indicates whether the key is in the hash package. The data variable is not updated.

Example

See "Example 3: Using the ADD and FIND Methods" on page 1662.

- "KEYS Method" on page 1703
- "DEFINEKEY Method" on page 1684
- "FIND_NEXT Method" on page 1690
- "FIND_PREV Method" on page 1692

FIND_NEXT Method

Sets the current list item to the next item in the current key's multiple item list and sets the data for the corresponding data variables.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**FIND_NEXT**( );

Form 2: *package*.**FIND_NEXT**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*data*]
specifies the variables into which to copy the data associated with the current key.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The FIND method determines whether the key exists in the hash package.

The HAS_NEXT method determines whether multiple data items are associated with the key. When you have determined that the key has another data item, that data item can be retrieved by using the FIND_NEXT method, which sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_NEXT and FIND_NEXT methods to traverse the list. If there is another item, the method returns a zero. Otherwise, it returns a nonzero value.

There are two ways to pass data variables to the FIND_NEXT method:

- implicit variable method (Form 1)

  The data variables are implied in the FIND_NEXT method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified data variables are passed explicitly to the FIND_NEXT method.

Example

This example uses the FIND_NEXT method to iterate through a table where several keys have multiple data items.

```
data testcases;
   dcl double k;
   dcl double expected;
   method init();
      k=0; expected=14; output; /* magic number */

      k=1; expected=1; output;
      k=2; expected=2; output;
      k=3; expected=1; output;
      k=4; expected=3; output;
      k=5; expected=2; output;
      k=6; expected=1; output;
      k=7; expected=1; output;
      k=8; expected=1; output;
      k=9; expected=1; output;
   end;
enddata;
run;

data inp;
   dcl double k v;
   method init();
      do k = 1 to 10; v = k * k; output; end;
      k = 2; v = 3;     output; /* newval < oldval */
      k = 4; v = 4242;  output; /* newval > oldval */
      k = 4; v = 0;     output; /* newval < oldval */
      k = 5; v = 25;    output; /* newval = oldval */
   end;
enddata;
run;

data _null_;
   dcl double k v;
   dcl package hash h(8, 'inp', 'ascending', '', '', 'multidata');
   method init();
      h.defineKey('k');
      h.defineData('k');
      h.defineData('v');
      h.defineDone();
   end;
   method run();
      dcl double actual;
      /*********************************************/
      set testcases;

      rc = h.find();
      if (rc ~= 0) then
         actual = h.get_num_items();
      else do;
         put k= rc=;
         actual = 0;
```

```
         do while (rc = 0);
            actual+1;
            rc = h.find_next();
            put k= rc=;
         end;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
k=1 rc=0
k=1 rc=4
k=2 rc=0
k=2 rc=0
k=2 rc=4
k=3 rc=0
k=3 rc=4
k=4 rc=0
k=4 rc=0
k=4 rc=0
k=4 rc=4
k=5 rc=0
k=5 rc=0
k=5 rc=4
k=6 rc=0
k=6 rc=4
k=7 rc=0
k=7 rc=4
k=8 rc=0
k=8 rc=4
k=9 rc=0
k=9 rc=4
```

Methods:

- "FIND Method" on page 1688
- "FIND_PREV Method" on page 1692
- "HAS_NEXT Method" on page 1698

FIND_PREV Method

Sets the current list item to the previous item in the current key's multiple item list and sets the data for the corresponding data variables.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**FIND_PREV**( );

Form 2: *package*.**FIND_PREV**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*data*]
specifies the variables into which to copy the data associated with the current key.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The FIND method determines whether the key exists in the hash package.

The HAS_PREV method determines whether multiple data items are associated with the key. When you have determined that the key has a previous data item, that data item can be retrieved by using the FIND_PREV method, which sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_PREV and FIND_PREV methods in addition to the HAS_NEXT and FIND_NEXT methods to traverse the list. If there is another item, the method returns a zero. Otherwise, it returns a nonzero value.

There are two ways to pass data variables to the FIND_PREVmethod:

- implicit variable method (Form 1)

  The data variables are implied in the FIND_PREV method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified data variables are passed explicitly to the FIND_PREV method.

Example

See "Example: Retrieving a Summary Value" on page 1739.

See Also

- "Implicit Variable and Variable List Methods" in *SAS DS2 Programmer's Guide*

Methods:

- "FIND Method" on page 1688
- "FIND_NEXT Method" on page 1690
- "HAS_PREV Method" on page 1700

FIRST Method

Returns the first value in the underlying hash package.

Applies to: Hash iterator package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**FIRST**( );

Form 2: *package*.**FIRST**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash iterator package variable.

[*data*]
specifies the variables into which to copy the data associated with the first hash item.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The FIRST method returns the first data item in the hash package. If you specified **YES** or **ASCENDING** in the DECLARE PACKAGE statement, the _NEW_ operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'least' key (smallest numeric value or first

alphabetic character). This occurs because the data items are sorted in ascending key-value order in the hash package. Repeated calls to the NEXT method iteratively traverse the hash package and return the data items in ascending key order.

Conversely, if you specified **DESCENDING** in the DECLARE PACKAGE statement, the _NEW_ operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'highest' key (largest numeric value or last alphabetic character). This occurs because the data items are sorted in descending key-value order in the hash package. Repeated calls to the NEXT method iteratively traverse the hash package and return the data items in descending key order.

Use the LAST method to return the last data item in the hash package.

Note: The FIRST method sets the data variable to the value of the data item so that it is available for use after the method call.

There are two ways to pass data variables to the FIRST method:

- implicit variable method (Form 1)

  The data variables are implied in the FIRST method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified data variables are passed explicitly to the FIRST method.

Example

The following example uses the FIRST, NEXT, PREV, and LAST methods when starting a new iteration at a different location within the hash package:

```
data _null_;
   dcl double x y rc;
   dcl package hash h([x], [y]);
   dcl package hiter hi('h');
   method init();
      do x = 1 to 10;
         y = 2*x;
         rc = h.add([x], [y]);
      end;
      do while (hi.next([y]) = 0);
         put y=;
      end;
      put;
      hi.first([y]);
      put y=;
      do while (hi.next([y]) = 0);
         put y=;
      end;
      put;
      do while (hi.prev([y]) = 0);
```

```
            put y=;
         end;
         put;
         hi.last([y]);
         put y=;
         do while (hi.prev([y]) = 0);
            put y=;
         end;
      end;
   enddata;
   run;
```

The following lines are written to the SAS log.

```
y=18
y=10
y=14
y=20
y=2
y=4
y=6
y=8
y=12
y=16

y=18

HASHEXP Method

Defines the hash package's internal table size. The size of the hash table is 2^n .

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**HASHEXP**(*exponent*);

Required Arguments

package
specifies an instance of the hash package variable.

exponent
specifies the power-of-2 for the internal table size.

Default 8

Data type INTEGER

Details

The value specified for the HASHEXP method is used as a power-of-two exponent to create the hash table size. For example, a value of 4 equates to a hash table size of 2^4, or 16. The maximum value for *exponent* is 16, which equates to a hash table size of 2^{16}.

The hash table size is not equal to the number of items that can be stored. Think of the hash table as an array of containers. A hash table size of 16 would have 16 containers. Each container can hold an infinite number of items. The efficiency of the hash tables lies in the ability of the hash function to map items to and retrieve items from the containers.

In order to maximize the efficiency of the hash package lookup routines, you should set the hash table size according to the amount of data in the hash package. Try different *exponent* values until you get the best result. For example, if the hash package contains one million items, a hash table size of 16 (hashexp = 4) would not be very efficient. A hash table size of 512 or 1024 (hashexp = 9 or 10) would result in better performance.

Note: Alternatively, you can use the *hashexp* parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify the hash table size.

See Also

- "Providing Initialization Data for a Hash Package" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: Hash Package" on page 1707

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

HAS_NEXT Method

Determines whether there is a next item in the current key's multiple data item list.

Applies to: Hash package

Syntax

package.**HAS_NEXT**( );

Required Argument

package
specifies an instance of the hash package variable.

Details

If a key has multiple data items, you can use the HAS_NEXT method to determine whether there is a next item in the current key's multiple data item list. If there is another item, the method returns a zero value. Otherwise, it returns a nonzero value.

The FIND method determines whether the key exists in the hash package. The HAS_NEXT method determines whether multiple data items are associated with the key. When you have determined that the key has another data item, that data item can be retrieved by using the FIND_NEXT method. The FIND_NEXT method sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_PREV and FIND_PREV methods in addition to the HAS_NEXT and FIND_NEXT methods to traverse the list.

Example: Finding Data Items

This example creates a hash package with one key having multiple data items. It uses the FIND and HAS_NEXT methods to search keys 1, 5, and 11 for the multiple data item.

```
data testdata (overwrite=yes);
   dcl double k v;
   method init();
      k=1; v=1; output;
      k=2; v=4; output;
      k=3; v=9; output;
      k=4; v=16; output;
      k=5; v=25; output;
      k=6; v=36; output;
      k=7; v=49; output;
      k=8; v=64; output;
      k=9; v=81; output;
      k=10; v=100; output;
      k=2; v=3; output;
      k=4; v=4242; output;
      k=4; v=0; output;
      k=5; v=25; output;
   end;
enddata;
run;

data _null_;
   dcl double k v rc;
   dcl package hash h(8, 'testdata', 'ascending', '', '', 'multidata');
   method init();
      h.defineKey('k');
      h.defineData('k');
      h.defineData('v');
      h.defineDone();
   end;
```

```
      method term();
         do k = 1, 5, 11;
            put k=;
            rc = h.find();
            put '..find=' rc;
            /*************************/
            do while (rc=0);
                put '    found:' k= v=;
                rc = h.has_next();
                put '..has_next=' rc;
                if (rc = 0) then do;
                   h.find_next();
                   /* ignore return code */
                   /* already know it from 'has_next', above */
                end;
            end;
            /*************************/
       end;
     end;
   enddata;
   run;
```

The following lines are written to the SAS log.

```
k=1
..find= 0
    found: k=1 v=1
..has_next= 4
k=5
..find= 0
    found: k=5 v=25
..has_next= 0
    found: k=5 v=25
..has_next= 4
k=11
..find= 4
```

- "Non-Unique Key and Data Pairs" in *SAS DS2 Programmer's Guide*

Methods:

- "FIND Method" on page 1688
- "FIND_NEXT Method" on page 1690
- "HAS_PREV Method" on page 1700

HAS_PREV Method

Determines whether there is a previous item in the current key's multiple data item list.

Applies to: Hash package

Syntax

package.**HAS_PREV**( );

Required Argument

package
specifies an instance of the hash package variable.

Details

If a key has multiple data items, you can use the HAS_PREV method to determine whether there is a previous item in the current key's multiple data item list. If there is a previous item, the method returns a zero. Otherwise, it returns a nonzero value.

The FIND method determines whether the key exists in the hash package. The HAS_NEXT method determines whether multiple data items are associated with the key. When you have determined that the key has a previous data item, that data item can be retrieved by using the FIND_PREV method. The FIND_PREV method sets the data variable to the value of the data item so that it is available for use after the method call. Once you are in the data item list, you can use the HAS_PREV and FIND_PREV methods in addition to the HAS_NEXT and FIND_NEXT methods to traverse the list.

Example

See "Example: Retrieving a Summary Value" on page 1739.

- "HAS_NEXT Method" on page 1698

ITEM_SIZE Attribute

Returns the size (in bytes) for an item in a hash package.

Applies to: Hash package

Syntax

variable-name=*package*.**ITEM_SIZE**;

Required Arguments

variable-name
specifies the name of the variable that contains the size of the item in the hash package after the method is complete.

package
specifies an instance of the hash package variable.

Details

The ITEM_SIZE attribute returns the size (in bytes) of an item, as well as the key and data variables and some internal information. To set an estimate of how much memory the hash package is using, specify the ITEM_SIZE and NUM_ITEMS attributes. The ITEM_SIZE attribute does not reflect the initial overhead that the hash package requires, nor does it take into account any necessary internal alignments. Therefore, using ITEM_SIZE does not provide exact memory usage, but it does return a good approximation.

Example

For an example, see the "NUM_ITEMS Attribute" on page 1714.

See Also

Attributes:

- "NUM_ITEMS Attribute" on page 1714

KEYS Method

Defines the key variables for the hash package using a variable list.

Applies to: Hash package

Notes: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

All variables that are passed to a hash instance must be global variables.

Syntax

package.**KEYS**(\[*keys*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*keys*]
specifies the names of the key variables using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The hash package uses unique lookup keys to store and retrieve data. The keys and data are variables, which you use to initialize the hash package by using dot notation method calls.

You can use a variable list to specify the key variables for a hash package using the KEYS method. When you have defined all key and data variables, you must call the DEFINEDONE method to complete initialization of the hash package.

Note: Alternatively, you can use the DEFINEKEYS method or constructors in the DECLARE PACKAGE statement to specify key variables.

Note: You can have a hash package that contains only key variables and no data variables. This is a keys-only hash package.

Keys and data consist of any number of character or numeric variables.

Example

The following example creates a hash package and defines the key and data variables:

```
declare hash h();
rc = h.keys([k]);
rc = h.data([d]);
rc = h.definedata();
end;
```

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

LAST Method

Returns the last value in the underlying hash package.

Applies to: Hash iterator package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**LAST**( );

Form 2: *package*.**LAST**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash iterator package variable.

[*data*]
specifies the variables into which to copy the data associated with the first hash item.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The LAST method returns the last data item in the hash package. If you specified **YES** or **ASCENDING** in the DECLARE PACKAGE statement, the _NEW_ operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the largest numeric value or that is the last alphabetic character. This is because the data items are sorted in ascending key-value order in the hash package.

Conversely, if you specified **DESCENDING** in the DECLARE PACKAGE statement, the _NEW_ operator, or the ORDERED method when you instantiate the hash package, then the data item that is returned is the smallest numeric value or the first alphabetic character. This is because the data items are sorted in descending key-value order in the hash package.

Use the FIRST method to return the first data item in the hash package.

There are two ways to pass data variables to the LAST method:

- implicit variable method (Form 1)

  The data variables are implied in the LAST method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified data variables are passed explicitly to the LAST method.

Example

For an example, see the "FIRST Method" on page 1694.

MULTIDATA Method

Specifies whether multiple data items are allowed for each key.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**MULTIDATA**(['*option*']);

Required Argument

package
specifies an instance of the hash package variable.

Optional Argument

'option'
option can be one of the following values:

'Y'
allows multiple data items for each key.

Alias 'Y' or 'MULTIDATA'

'N'
reports an error to the log if a duplicate key is found.

Alias 'N' or 'SINGLEDATA'

Default NO

Details

By default, all of the keys in a hash package are unique. This means one set of data variables exists for each key. In some situations, you might want to have duplicate keys in the hash package, that is, associate more than one set of data variables with a key.

If the table contains duplicate keys, by default, the first instance is stored in the hash package and subsequent instances are ignored. To store the last instance in the hash package, use the DUPLICATE method. The DUPLICATE method also writes an error to the SAS log if there is a duplicate key.

However, the hash package allows storage of multiple values for each key if you use the MULTIDATA parameter or method. The hash package keeps the multiple values in a list that is associated with the key. This list can be traversed and manipulated by using several methods such as HAS_NEXT or FIND_NEXT.

Note: Alternatively, you can use the *multidata* parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify whether multiple data items are allowed for each key.

See Also

- "Non-Unique Key and Data Pairs" in *SAS DS2 Programmer's Guide*

Methods:

- "DUPLICATE Method" on page 1686

Operators:

- "_NEW_ Operator: Hash Package" on page 1707

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

NEW Operator: Hash Package

Constructs an instance of a hash package.

Notes:

Braces in the syntax convention indicate a syntax grouping. The escape character (\ ) before a brace indicates that the brace is required in the syntax. *sql-text* must be enclosed in braces ({ }).

The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

All variables that are passed to a hash instance must be global variables.

Syntax

Form 1: *package-variable*=**_NEW_ HASH**();

Form 2: *package-variable*=**_NEW_ HASH**
(*hashexp*, '*datasource*', '*ordered*', '*duplicate* ', '*suminc*', '*multidata*');

Form 3: *package-variable*=**_NEW_ HASH**
(\[*keys*\], \[*data*\], [*hashexp*, '*datasource*', '*ordered*', '*duplicate* ', '*suminc*', '*multidata*']);

Form 4: *package-variable*=**_NEW_ HASH**
(\[*keys*\], [*hashexp*, {'*datasource*' | \{*sql-text*\} }, '*ordered*', '*duplicate* ', '*suminc*', '*multidata*']);

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Optional Arguments

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the data variables by using a variable list and associates them with the specified keys.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

{*sql-text*}
is any valid FedSQL SELECT statement that resolves to a set of table rows.

Restriction This argument is not supported on the CAS server.

Requirement The FedSQL query must be enclosed in braces ({ }).

Note The FedSQL query is specified in the following form: {`SELECT <select-list> FROM <table-specification>;`}. For more information, see the SELECT statement in the *SAS FedSQL Language Reference*.

Arguments

hashexp
is the hash package's internal table size, where the size of the hash table is 2^n.

The value of hashexp is used as a power-of-two exponent to create the hash table size. For example, a value of 4 for hashexp equates to a hash table size of 2^4, or 16. The maximum value for hashexp is 16, which equates to a hash table size of 2^{16}.

The hash table size is not equal to the number of items that can be stored. Think of the hash table as an array of containers. A hash table size of 16 would have 16 containers. Each container can hold an infinite number of items. The efficiency of the hash tables lies in the ability of the hash function to map items to and retrieve items from the containers.

In order to maximize the efficiency of the hash package lookup routines, you should set the hash table size according to the amount of data in the hash package. Try different hashexp values until you get the best result. For example, if the hash package contains one million items, a hash table size of 16 (hashexp = 4) would not be very efficient. A hash table size of 512 or 1024 (hashexp = 9 or 10) would result in better performance.

Requirement Either a placeholder of –1 or a value for *hashexp* must be entered. If the place holder is entered, then a default value of 8, which equates to a hash table size of 2^8 or 256, is used.

Data type INTEGER

'datasource'
is the name of a table to load into the hash package.

The name of the table can be a literal or a character variable. The table name must be enclosed in single quotation marks.

Restriction If the datasource argument is not null, then the _NEW_ operator is not supported on the CAS server.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *datasource* must be entered. If the place holder is entered, then the hash is not loaded from a data source.

'ordered'
specifies whether or how the data is returned in key-value order if you use the hash package with a hash iterator package or if you use the hash package OUTPUT method. Here are the valid values:

'ASCENDING'
Data is returned in ascending key-value order. Specifying '**ASCENDING**' is the same as specifying '**YES**'.

Alias 'A'

'DESCENDING'
Data is returned in descending key-value order.

Alias 'D'

'YES'
Data is returned in ascending key-value order. Specifying '**YES**' is the same as specifying '**ASCENDING**'.

'NO'
Data is returned in an undefined order.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *ordered* must be entered. If the place holder is entered, then a default ordering of 'NO' is used.

'duplicate'
determines whether to ignore duplicate keys when loading a table into the hash package. The default is to store the first key and ignore all subsequent duplicates. Here are the valid values:

'REPLACE'
stores the last duplicate key record.

'ERROR'
reports an error to the log if a duplicate key is found.

'ADD'
stores the first key record found and not any of the duplicates.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *duplicate* must be entered. If the place holder is entered, then a default of 'ADD' is used.

See "Example 3: Using the Duplicate Parameter with a Hash Package" on page 1676

'suminc'
specifies a variable that maintains a summary count of hash package keys.

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for *suminc* must be entered.

Note This variable holds the sum increment–that is, how much to add to the key summary for each reference to the key. The *suminc* value treats a missing or null value as zero, like the SUM function. For example, a key summary changes using the current value of the variable.

'multidata'
specifies whether multiple data items are allowed for each key. Here are the valid values:

'YES'
allows multiple data items for each key

Alias 'Y' or 'MULTIDATA'

'NO'
allows only one data item for each key

Alias 'N' or 'SINGLEDATA'

Requirement Either a placeholder of an empty string in quotation marks ('') or a value for ordered must be entered. If the place holder is entered, then a default ordering of 'NO' is used.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a hash package variable using the DECLARE PACKAGE statement. After you declare a hash package variable, use the _NEW_ operator to instantiate an instance of the hash package and assign the new package instance to the hash package variable.

```
declare package hash myhash();
myhash = _new_ hash();
```

A particular hash package instance is defined by a set of key variables, a set of data variables, and optional initialization data. A hash package instance can be defined either fully at construction or at construction and through a subsequent series of method calls. If key variables and data variables are specified when the hash package instance is constructed (Forms 3 and 4), then the hash instance is constructed as fully defined. If key variables and data variables are not provided when the hash package instance is constructed (Form 2), then additional definition of the hash instance can be specified with a subsequent series of method calls followed by a single DEFINEDONE method call. The DEFINEDONE method indicates that specification of key variables, data variables, and other initialization data is complete.

For example, you can provide initialization data by using parameters in the constructor syntax for the hash package

```
declare package hash h;
h = _new_ hash(0, 'mytable', 'yes', 'replace', 'sumnum', 'y');
```

Note: You can use the DECLARE PACKAGE statement constructor to declare and instantiate a hash or hash iterator package in one step. For more information, see "Defining a Hash Instance By Using Constructors" in *SAS DS2 Programmer's Guide* and the "DECLARE PACKAGE Statement: Hash Package" on page 1670.

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

Operators:

- "_NEW_ Operator: Hash Iterator Package" on page 1712

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

NEW Operator: Hash Iterator Package

Creates an instance of a hash iterator package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_ HITER** (*'hash-name'*);

Required Arguments

package-variable
specifies a name that can reference an instance of the package.

'hash-name'
specifies the hash package that is associated with the hash iterator package.

Requirement You must declare and instantiate a hash package before you create a hash iterator package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a hash iterator package variable using the DECLARE PACKAGE statement. After you declare a hash iterator package variable, use the _NEW_ operator to instantiate an instance of the hash iterator package and assign the new package instance to the hash iterator package variable.

```
declare package hiter myiter;
myiter = _new_ hiter('myhash');
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a hash iterator package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package hiter myiter('myhash');
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

Operators:

- "_NEW_ Operator: Hash Package" on page 1707

Statements:

- "DECLARE PACKAGE Statement: Hash Iterator Package" on page 1679

NEXT Method

Returns the next value in the underlying hash package.

Applies to: Hash iterator package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**NEXT**( );

Form 2: *package*.**NEXT**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash iterator package variable.

[*data*]
specifies the variables into which to copy the data associated with the next hash item.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

Use the NEXT method iteratively to traverse the hash package and return the data items in key order. The FIRST method returns the first data item in the hash package. You can use the PREV method to return the previous data item in the hash package.

There are two ways to pass data variables to the NEXT method:

- implicit variable method (Form 1)

  The data variables are implied in the NEXT method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified data variables are passed explicitly to the NEXT method.

Example

For an example, see the "FIRST Method" on page 1694.

See Also

Methods:

- "FIRST Method" on page 1694
- "PREV Method" on page 1720

NUM_ITEMS Attribute

Returns the number of items in the hash package.

Applies to: Hash package

Syntax

variable-name=*package*.**NUM_ITEMS**;

Required Arguments

variable-name
specifies the name of a variable that contains the number of items in the hash package after the method is complete.

package
specifies an instance of the hash package variable.

Details

The NUM_ITEMS attribute returns the number of key/data pairs stored in the hash table.

Example

The following example uses the NUM_ITEMS attribute to count the number of items within the hash package and the ITEM_SIZE attribute to report the size of an item in the hash package.

```
data _null_;
   dcl int item_size num_items;
   dcl double x;
   dcl timestamp t;
   dcl package hash h(8, '', 'yes');
   dcl package hiter hi('h');
   method init();
      rc = h.defineKey('t');
      rc = h.defineData('t');
      rc = h.defineData('x');
      rc = h.defineDone();

      item_size = h.item_size;
      num_items = h.num_items;
      put item_size=;
      put num_items=;
      put;

      t = timestamp '1927-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1928-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:37.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1930-09-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1930-10-25 13:52:37.01'; x = 1; h.add();

      num_items = h.num_items;
      put num_items=;

   do while (hi.next() = 0);
      put t= x=;
   end;
   put;
```

```
        t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.remove();
        t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.remove();

        num_items = h.num_items;
        put num_items=;

        do while (hi.next() = 0);
           put t= x=;
        end;
     end;
  enddata;
  run;
```

The following lines are written to the SAS log:

```
item_size=72
num_items=0

num_items=11
t=1927-08-24 12:51:36 x=1
t=1928-08-24 12:51:36 x=1
t=1929-08-24 12:51:36 x=1
t=1929-09-24 12:51:36 x=1
t=1929-09-25 12:51:36 x=1
t=1929-09-25 13:51:36 x=1
t=1929-09-25 13:52:36 x=1
t=1929-09-25 13:52:37 x=1
t=1929-09-25 13:52:37.010000000 x=1
t=1930-09-25 13:52:37.010000000 x=1
t=1930-10-25 13:52:37.010000000 x=1

num_items=9
t=1927-08-24 12:51:36 x=1
t=1928-08-24 12:51:36 x=1
t=1929-08-24 12:51:36 x=1
t=1929-09-24 12:51:36 x=1
t=1929-09-25 12:51:36 x=1
t=1929-09-25 13:52:37 x=1
t=1929-09-25 13:52:37.010000000 x=1
t=1930-09-25 13:52:37.010000000 x=1
t=1930-10-25 13:52:37.010000000 x=1
```

See Also

Attributes:

- “ITEM_SIZE Attribute” on page 1702

ORDERED Method

Specifies whether or how the data is returned in key-value order if you use the hash package with a hash iterator package or if you use the hash package OUTPUT method.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**ORDERED**('*option*');

Required Arguments

package
specifies an instance of the hash package variable.

option
option can be one of the following values:

'ASCENDING'
Data is returned in ascending key-value order. Specifying '**ASCENDING**' is the same as specifying '**YES**'.

Alias 'A'

'DESCENDING'
Data is returned in descending key-value order.

Alias 'D'

'YES'
Data is returned in ascending key-value order. Specifying '**YES**' is the same as specifying '**ASCENDING**'.

'NO'
Data is returned in an undefined order.

Default NO

Details

If you specify **YES** or **ASCENDING** in the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'least' key (smallest numeric value or first alphabetic character). This occurs because the data items are sorted in ascending key-value order in the hash package. Repeated calls to the NEXT method iteratively traverse the hash package and return the data items in ascending key order.

Conversely, if you specify **DESCENDING** parameter in the ORDERED method when you instantiate the hash package, then the data item that is returned is the one with the 'highest' key (largest numeric value or last alphabetic character). This occurs because the data items are sorted in descending key-value order in the hash

package. Repeated calls to the NEXT method iteratively traverse the hash package and return the data items in descending key order.

Use the FIRST method returns the first data item in the hash package. Use the LAST method to return the last data item in the hash package.

Note: Alternatively, you can use the *ordered* parameter in the DECLARE PACKAGE statement or the _NEW_ operator to specify whether the data is returned in key-value order .

- "FIRST Method" on page 1694
- "LAST Method" on page 1704

Operators:

- "_NEW_ Operator: Hash Package" on page 1707

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

OUTPUT Method

Creates a table that contains the data in the hash package.

Applies to: Hash package

Restriction: This method is not supported on the CAS server.

Syntax

package.**OUTPUT** (['*output-table*']);

Required Arguments

package
specifies an instance of the hash iterator package variable.

['*output-table***']**
specifies the name of the output table.

The name of the hash table can be a literal or character variable.

Tip The name of the table can be a literal or a character variable. If a literal is used, the table name must be enclosed in single quotation marks.

Details

Hash package keys are not automatically stored as part of the output table. The keys must be defined as data items by using the DEFINEDATA method, the DATA method, or the DECLARE PACKAGE statement to be included in the output table.

Example

```
data a(overwrite=yes);
   dcl double x;
      method init();
         do x = 1 to 10;
            output;
         end;
      end;
enddata;
run;
data _null_;
   method init();
      dcl package hash h(4, 'a');
      rc = h.defineData('x');
      rc = h.defineKey('x');
      rc = h.defineDone();
      x = 11;
      h.add();
      x = 12;
      h.add();
      x = 13;
      h.add();
      x = 14;
      h.add();
      rc = h.output('out');
   end;
enddata;
run;
```

Statements:

- "DECLARE PACKAGE Statement: Hash Package" on page 1670

PREV Method

Returns the previous value in the underlying hash package.

Applies to: Hash iterator package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**PREV**( );

Form 2: *package*.**PREV**(\[*data*\]);

Required Arguments

package
specifies an instance of the hash iterator package variable.

[*data*]
specifies the variables into which to copy the data associated with the previous hash item.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

Use the PREV method iteratively to traverse the hash package and return the data items in reverse key order. The FIRST method returns the first data item in the hash package. The LAST method returns the last data item in the hash package. You can use the NEXT method to return the next data item in the hash package.

There are two ways to pass data variables to the PREV method:

- implicit variable method (Form 1)

  The data variables are implied in the PREV method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified data variables are passed explicitly to the PREV method.

Example

For an example, see the "FIRST Method" on page 1694.

- "NEXT Method" on page 1713

REF Method

Consolidates a FIND and ADD methods into a single method call.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**REF**( );

Form 2: *package*.**REF**(\[*keys*\], \[*data*\]);

Form 3: *package*.**REF**(\[*keys*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key variables by using a variable list.

Restriction If you specify only keys, the FIND method works only for key-only hash packages.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the variables into which to add the hash data.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

You can consolidate FIND and ADD methods into a single REF method.

There are two ways to pass key and data variables to the REF method:

- implicit variable method (Form 1)

  The key and data variables are implied in the REF method invocation and do not have to be specified.

- variable list method (Forms 2 and 3)

  The specified key and data variables are passed explicitly to the REF method. If the hash package contains only keys, use Form 3.

Example

```
data _null_;
   dcl double x y;
   dcl int rc;
   dcl package hash h([x], [x y]);
   dcl package hiter hi('h');
   method init();
      x = 7; y = 13;
      rc = h.add([x], [x y]);
      put x= rc=;
      do x = 5 to 10;
         y = 2*x;
         rc = h.ref([x], [x y]);
         put x= rc=;
      end;
      do while (hi.next([x y]) = 0);
         put x= y=;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
x=7 rc=0
x=5 rc=0
x=6 rc=0
x=7 rc=0
x=8 rc=0
x=9 rc=0
x=10 rc=0
x=9 y=18
x=5 y=10
x=7 y=13
x=10 y=20
x=6 y=12
x=8 y=16
```

- "FIND Method" on page 1688

REMOVE Method

Removes the data that is associated with the specified key from the hash package.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**REMOVE**( );

Form 2: *package*.**REMOVE**(\[*keys*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The REMOVE method uses the values in the key variables to find and remove an existing key in a hash table.

You specify the key and then use the REMOVE method to remove the key and data in a hash package.

There are two ways to pass key variables to the REMOVE method:

- implicit variable method (Form 1)

  The key variables are implied in the REMOVE method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified key variables are passed explicitly to the REMOVE method.

Note: The REMOVE method does not modify the value of data variables. It removes only the value in the hash package.

Note: If you specify **YES** the DECLARE PACKAGE statement, the _NEW_ operator, or the MULTIDATA method when you instantiate the hash package, the REMOVE method removes all data items for the specified key.

Example

```
data _null_;
   dcl double x rc;
   dcl timestamp t;
   dcl package hash h(0, '', 'yes');
   dcl package hiter hi('h');
   method init();
      rc = h.Keys([t]);
      rc = h.Data([t x]);
      rc = h.defineDone();
      t = timestamp '1927-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1928-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:37.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1930-09-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1930-10-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      do while (hi.next([t x]) = 0);
         put t= x=;
         t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      end;
      put '************************************';
      t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.remove();
      t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.remove();
      t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      do while (hi.next([t x]) = 0);
         put t= x=;
         t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      end;
   end;
```

```
enddata;
run;
```

The following lines are written to the SAS log.

```
t=1927-08-24 12:51:36 x=1

- "KEYS Method" on page 1703

REMOVEALL Method

Removes the data that is associated with all keys from the hash package.

Applies to: Hash package

Syntax

Form 1: *package*.**REMOVEALL**();

Form 2: *package*.**REMOVEALL**(\[*keys*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The REMOVEALL method deletes both the keys and the data from the hash package.

There are two ways to pass key variables to the REMOVEALL method:

- implicit variable method (Form 1)

  The key variables are implied in the REMOVEALL method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified key variables are passed explicitly to the REMOVEALL method.

Note: The REMOVEALL method does not modify the value of data variables. It removes only the value in the hash package.

REMOVEDUP Method

Removes the data that is associated with the current key's current data item from the hash package.

Applies to: Hash package

Syntax

package.**REMOVEDUP**( );

Required Argument

package
specifies an instance of the hash package variable.

Details

The REMOVEDUP method deletes the current data item from the hash package for keys that have multiple data items.

Note: The REMOVEDUP method does not modify the value of data variables. It removes only the value in the hash package.

Note: If only one data item is in the key's data item list, the key and data are removed from the hash package.

Comparisons

The REMOVEDUP method removes the data that is associated with the current key's current data item from the hash package. The REMOVE method removes the data that is associated with the specified key from the hash package.

Example

This example creates a hash package where several keys have multiple data items. Duplicate data items in the key are removed.

```
data testdup;
```

```
   length key data 8;
   input key data;
   datalines;
   1 10
   2 11
   1 15
   3 20
   2 16
   2 9
   3 100
   5 5
   1 5
   4 6
   5 99
;

proc ds2;
data _null_;
   dcl double key "data" k d;
   method init();
      dcl package hash  h([key], [key "data"], 8, 'testdup', 'yes', '',
         '', 'yes');
      dcl package hiter i(h);
      dcl int rc;

      do k = 1 to 5;
         do while (h.find([k], [k d]) = 0 and h.has_next() = 0);
            h.find_next([k d]);
            h.removedup ();
         end;
      end;

      rc = i.first([k d]);
      do while (rc = 0);
         put k= d=;
         rc = i.next([k d]);
      end;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
key=1 data=10
key=2 data=11
key=3 data=20
key=4 data=6
key=5 data=5
```

See Also

- "Replacing and Removing Data" in *SAS DS2 Programmer's Guide*

Methods:

- "REMOVE Method" on page 1723
- "REMOVEALL Method" on page 1725

REPLACE Method

Replaces the data that is associated with the specified key with new data.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**REPLACE**( );

Form 2: *package*.**REPLACE**(\[*keys*\], \[*data*\]);

Form 3: *package*.**REPLACE**(\[*keys*\]);

Required Arguments

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key values by using a variable list.

Restriction If you specify only keys, the REPLACE method works only for key-only hash packages.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the variables for which the data is replaced.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The REPLACE method uses the values in the key variables to find a key/data pair in the hash table. If a pair is found, the data is replaced with the current value in the data variables (Forms 1 and 2).

For hash packages that have only keys (Form 3), the only effect that the REPLACE method has is that the summary statistics for the keys is updated.

Example

```
data _null_;
   dcl double x rc;
   dcl timestamp t;
   dcl package hash h(0, '', 'yes');
   dcl package hiter hi('h');
   method init();
      rc = h.defineKey('t');
      rc = h.defineData('t');
      rc = h.defineData('x');
      rc = h.defineDone();
      t = timestamp '1927-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1928-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-08-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-24 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 12:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:51:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:36.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:37.00'; x = 1; h.add();
      t = timestamp '1929-09-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1930-09-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1930-10-25 13:52:37.01'; x = 1; h.add();
      t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      do while (hi.next() = 0);
         put t= x=;
         t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      end;
      put '************************************';
      t = timestamp '1929-09-25 13:51:36.00'; x = 64; h.replace();
      t = timestamp '1929-09-25 13:52:36.00'; x = 64; h.replace();
      t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      do while (hi.next() = 0);
         put t= x=;
         t = timestamp '1999-12-01 12:00:00.00'; x = 999;
      end;
   end;
enddata;
```

The following lines are written to the SAS log.

```
t=1927-08-24 12:51:36 x=1
t=1928-08-24 12:51:36 x=1

- "Replacing and Removing Data" in *SAS DS2 Programmer's Guide*

Methods:

- "REPLACEDUP Method" on page 1731

REPLACEDUP Method

Replaces the data that is associated with the current key's current data item with new data.

Applies to: Hash package

Syntax

package.**REPLACEDUP**( );

Required Argument

package
specifies an instance of the hash package variable.

Details

The REPLACEDUP method replaces the current data item from the hash package for keys that have multiple data items.

Note: The REPLACEDUP method does not replace the value of the data variable with the value of the data item. It replaces only the value in the hash package.

Note: If you call the REPLACEDUP method and the key is not found, then the key and data are added to the hash package.

Comparisons

The REPLACEDUP method replaces the data that is associated with the current key's current data item with new data. The REPLACE method replaces the data that is associated with the specified key with new data.

Example

This example creates a hash package where several keys have multiple data items. When a duplicate data item is found, 300 is added to the value of the data item.

```
data testdup;
   length key data 8;
   input key data;
   datalines;
   1 10
   2 11
   1 15
   3 20
   2 16
   2 9
   3 100
   5 5
   1 5
   4 6
   5 99
;
proc ds2;
data _null_;
   dcl double key "data" k d;
   method init();
      dcl package hash h([key], [key "data"], 8, 'testdup','yes', '', '', 'yes');
      dcl package hiter i(h);
      dcl int rc;

      do k = 1 to 5;
```

```
         do while (h.find([k], [k d]) = 0);
            put k= d=;
                  do while (h.has_next() = 0);
               h.find_next([k d]);
               put 'dup ' k= d=;
               d = d + 300;
               h.replacedup ();
                     h.has_next();
            end;
         end;
      end;

      put 'iterating...';
      rc = i.first([k d]);
      do while (rc = 0);
         put k= d=;
         rc = i.next([k d]);
      end;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
key=1 data=10
dup key=1 15
dup key=1 5
key=2 data=11
dup key=2 16
dup key=2 9
key=3 data=20
dup key=3 100
key=4 data=6
key=5 data=5
dup key=5 99
iterating...
key=1 data=10
key=1 data=315
key=1 data=305
key=2 data=11
key=2 data=316
key=2 data=309
key=3 data=20
key=3 data=400
key=4 data=6
key=5 data=5
key=5 data=399
```

Methods:

- "REPLACE Method" on page 1729

SETCUR Method

Specifies a starting key item for iteration.

Applies to: Hash iterator package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package*.**SETCUR**( );

Form 2: *package*.**SETCUR**(\[*keys*\], \[*data*\]);

Required Arguments

package
specifies the name of the hash iterator package variable.

[*keys*]
specifies the key variables by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

[*data*]
specifies the variables into which to store the data item.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

The hash iterator enables you to start iteration on any item in the hash package. The SETCUR method sets the starting key for iteration. You reference the starting item with the specified key variables. If the item exists, the data associated with the item is stored in the data variables.

You can use the FIRST or LAST methods to start iteration on the first or last item, respectively.

There are two ways to pass key and data variables to the SETCUR method:

- implicit variable method (Form 1)

  The key and data variables are implied in the SETCUR method invocation and do not have to be specified.

- variable list method (Form 2)

The specified key and data variables are passed explicitly to the SETCUR method.

Example

The following example uses the SETCUR method to start iteration at RA= 18 31.6 instead of the first or last items:

```
declare hiter iter('myhash');
myhash.defineKey('ra');
myhash.defineData('obj', 'ra');
myhash.defineDone();
ra='18 31.6';
rc = iter.setcur();
   do while (rc = 0);
      put obj= ra=;
      rc = iter.next();
   end;
```

- "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Methods:

- "FIRST Method" on page 1694
- "LAST Method" on page 1704

SUM Method

Retrieves the summary value for a given key from the hash table and stores the value in a variable.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *summary-variable*=*package*.**SUM**();

Form 2: *summary-variable*= *package*.**SUM**(\[*keys*\]);

Required Arguments

summary-variable
specifies a variable that holds the current summary value of the current key.

Note A return code that specifies success or failure is not returned by the method.

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

You use the SUM method to retrieve key summaries from the hash package. The SUM method retrieves the summary value for a given key when only one data item exists per key. For more information, see "Maintaining Key Summaries" in *SAS DS2 Programmer's Guide*.

There are two ways to pass key variables to the SUM method:

- implicit variable method (Form 1)

  The key variables are implied in the SUM method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified key variables are passed explicitly to the SUM method.

Comparisons

The SUMDUP method retrieves the summary value for the current data item of the current key when more than one data item exists for a key.

Example: Retrieving the Key Summary for a Given Key

The following example uses the SUM method to retrieve the key summary for a given key, 99.

```
data _null_;
   declare double k count total;
   declare package hash myhash(0, '', 'a', '', 'count');
   method init();
```

```
        myhash.defineKey('k');
        myhash.defineDone();

        k = 99;
        count = 1;
        myhash.add();

        /* COUNT is given the value 2.5 and the */
        /* FIND sets the summary to 3.5*/
        count = 2.5;
        myhash.find();

        /* The COUNT of 3 is added to the FIND and */
        /* sets the summary to 6.5. */
        count = 3;
        myhash.find();

        /* The COUNT of -1 sets the summary to 5.5. */
        count = -1;
        myhash.find();

        /* The SUM method gives the current value of */
        /* the key summary to the variable TOTAL. */
        total = myhash.sum();

        /* The PUT statement prints total=5.5 in the log. */
        put total=;

    end;
enddata;
run;
```

- "Implicit Variable and Variable List Methods" in *SAS DS2 Programmer's Guide*

Methods:

- "SUMDUP Method" on page 1737

SUMDUP Method

Retrieves the summary value for the current data item of the current key and stores the value in a variable.

Applies to: Hash package

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *summary-variable*=*package*.**SUMDUP**();

Form 2: *summary-variable*= *package*.**SUMDUP**(\[*keys*\]);

Required Arguments

summary-variable
specifies a variable that holds the current summary value for the current data item of the current key.

Note A return code that specifies success or failure is not returned by the method.

package
specifies an instance of the hash package variable.

[*keys*]
specifies the key values by using a variable list.

See "DS2 Variable Lists" in *SAS DS2 Programmer's Guide*

Details

You use the SUMDUP method to retrieve key summaries from the hash package when a key has multiple data items. For more information, see "Maintaining Key Summaries" in *SAS DS2 Programmer's Guide*.

There are two ways to pass key variables to the SUMDUP method:

- implicit variable method (Form 1)

  The key variables are implied in the SUMDUP method invocation and do not have to be specified.

- variable list method (Form 2)

  The specified key variables are passed explicitly to the SUMDUP method.

Comparisons

The SUMDUP method retrieves the summary value for the current data item of the current key when more than one data item exists for a key. The SUM method retrieves the summary value for a given key when only one data item exists per key.

Example: Retrieving a Summary Value

The following example uses the SUMDUP method to retrieve the summary value for the current data item.

```
data hashinp;
   dcl double k v;
   method init();
      k=1; v=2; output;
      k=1; v=4; output;
      k=1; v=8; output;
      k=2; v=2; output;
      k=3; v=4; output;
      k=2; v=8; output;
    end;
enddata;
run;

data results(keep=(k v sumres));
   dcl double k v si sumres;
   dcl package hash h(8, 'hashinp', 'ascending', '', 'si', 'multidata');

   method testsuminc(double kval, double suminc);
      dcl double rc;
      si = suminc;
      put 'input:' kval= suminc=;
      k=kval; rc=h.find();
      if (rc=0) then do;
         rc=h.has_next();
         do while(rc=0);
            put 'next:' k= v=;
            h.find_next();
            rc=h.has_next();
         end;
         rc=h.has_prev();
          do while(rc=0);
             put 'prev:' k= v=;
             h.find_prev();
             rc=h.has_prev();
          end;
          si=0;
         k=kval; rc=h.find();
          do while(rc=0);
             sumres = h.sumdup();
            output;
             rc=h.find_next();
         end;
      end;
   end;

   method init();
      h.defineKey('k');
      h.defineData('k');
      h.defineData('v');
      h.defineDone();
         testsuminc(1.0, 2.0);
```

```
         testsuminc(2.0, 20.0);
         testsuminc(3.0, 4.0);
   end;
   method term();
      dcl package hiter hi('h');
      rc=hi.first();
      do while (rc=0);
         put 'final:' k= v=;
         rc=hi.next();
      end;
    end;
enddata;
run;

data _null_;
   method run();
      set results;
      put k= v= sumres=;
    end;
enddata;
run;
```

The following lines are written to the SAS log.

```
k=1 v=2 sumres=4
k=1 v=4 sumres=4
k=1 v=8 sumres=2
k=2 v=2 sumres=40
k=2 v=8 sumres=20
k=3 v=4 sumres=4
```

SUMINC Method

Specifies a variable that maintains a summary count of hash package keys.

Applies to: Hash package

Note: All variables that are passed to a hash instance must be global variables.

Syntax

package.**SUMINC**(*suminc-variable*);

Required Arguments

package
specifies an instance of the hash package variable.

suminc-variable
specifies a variable that maintains a summary count of hash package keys.

Details

You can maintain a summary count for a hash package key by using the SUMINC parameter or method. SUMINC instructs the hash package to allocate internal storage in each record to store a summary value in the record each time that the record is used by a FIND, CHECK, or REF method. The SUMINC value is also used to maintain a summary count of hash parameter keys after a FIND, CHECK, or REF method. SUMINC is given a variable, which holds the sum increment, that is, how much to add to the key summary for each reference to the key. The SUMINC value can be greater than, less than, or equal to 0.

The SUMINC value is also used to initialize the summary on an ADD method. Each time the ADD method occurs, the key to the SUMINC value is initialized.

The SUMINC variable treats a missing or null value as zero, like the SUM function. For example, a key summary changes using the current value of the variable.

For more information, see "Maintaining Key Summaries" in *SAS DS2 Programmer's Guide*.

Note: Alternatively, you can use the *suminc* parameter in the DECLARE PACKAGE statement or the _NEW_ operator to retrieve the summary value for the current data item of the current key.

Example

See the example in the "SUMDUP Method" on page 1737.

DS2 HTTP Package Methods, Operators, and Statements

Method Naming Convention

When discussing a similar set of methods, this document uses a short name and an asterisk (*) to designate the set of methods as a whole.

For example, when the discussion involves both the SETREQUESTBODYASBINARY and SETREQUESTBODYASSTRING methods, the text refers to “the SETREQUESTBODY* methods”.

SAS LOCKDOWN Support

The DS2 HTTP package supports SAS LOCKDOWN restrictions. The package is not available when the SAS HTTP (or URL) method is placed in a locked-down state.

Dictionary

ABORT Method

Stops the execution of the HTTP method.

Syntax

package.**ABORT**( );

Required Argument

package
specifies an instance of the HTTP package variable.

Details

Call the ABORT method to stop the HTTP method that is currently running. The ABORT method is useful when you are streaming data and decide that you do not need to see the entire response body.

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "EXECUTEMETHOD Method" on page 1758
- "EXECUTEMETHODSTREAM Method" on page 1759

ADDREQUESTHEADER Method

Adds a header to the HTTP method request.

Syntax

package.**ADDREQUESTHEADER**(*'name'*, *'value'*);

Required Arguments

package
specifies an instance of the HTTP package variable.

'name'
specifies the name of the header field.

'value'
specifies the value of the header field.

Details

The header is appended to the end of the list of headers.

Example

```
h.addRequestHeader('Cookie', ' SSID=3lk3q84095jk79lgjf');
```

- "CREATEPOSTMETHOD Method" on page 1754

ADDSASOAUTHTOKEN Method

Searches the SAS environment for an OAuth access token. If a token is found, it is set as the OAuth token for the request.

Syntax

package.**ADDSASOAUTHTOKEN**( );

Required Argument

package
specifies an instance of the HTTP package variable.

Details

Open Authorization (OAuth) is an open standard for token-based authentication and authorization on the internet. OAuth is designed to work with HTTP and allows access tokens to be issued to third-party clients by an authorization server, with the approval of the resource owner. The third-party client then uses the access token to access the protected resources that are hosted by the resource server.

For the HTTP package, use the ADDSASOAUTHTOKEN method to allow SAS to search the environment for an OAuth access token that will be added to the request header as a Bearer value of an Authorization header field.

For more information on OAuth, see OAuth 2.0.

Note: A return code value of 0 indicates success, a value of 1 indicates failure, a value of 3 indicates a token is not found, and a value of 4 indicates that the token is expired.

Comparisons

You allow SAS to search the environment for an OAuth access token with the ADDSASOAUTHTOKEN method. You provide the OAuth access token with the SETOAUTHTOKEN method.

See Also

Methods:

- "SETOAUTHTOKEN Method" on page 1770

CREATEGETMETHOD Method

Creates an HTTP GET method to retrieve a resource from a web server.

Syntax

package.**CREATEGETMETHOD** {( ) | (*'url'*)};

Required Arguments

package
specifies an instance of the HTTP package variable.

( ) | (*'url'*)
either generates the HTTP GET method without a URL or specifies the URL of the resource.

Tip The URL can include query strings (name/value pairs).

Details

Use the CREATEGETMETHOD method to create an HTTP GET method. After you create the GET method, call one of the EXECUTEMETHOD* methods to request the specified resource from the web server.

The URL must be set either as an argument in the CREATEGETMETHOD method or by using the SETURL method.

Examples

Example 1: Create a GET Method and Retrieve an HTTP Resource

The following example requests an HTTP resource and displays the headers and body of the response from the web server.

```
data _null_;
  method init();
    declare package http h();
    declare varchar(1024) character set utf8 body headers;
    declare int rc status;

    /* Build and send a GET method for the 'FR' resource */
    h.createGetMethod('http://api.worldbank.org/countries/FR');
    h.executeMethod();

    /* If the resource was returned by the server, show the response */
    status = h.getStatusCode();   /* get the HTTP status code */
    put 'Country code: FR, executeMethod() status:' status;
    if status eq 200 then do;     /* 200 = OK */
      /* retrieve the headers from the response that came from the server */
      h.getResponseHeadersAsString(headers, rc);
      put 'Headers:';
      put headers;
      /* retrieve the body from the response that came from the server */
      h.getResponseBodyAsString(body, rc);
      put 'Body:';
      put body;
    end;
  end;
enddata; run;
```

The following lines are written to the log:

```
Country code: FR, executeMethod() status: 200
Headers:
HTTP/1.1 200 OK
Content-Length: 627
Content-Type: text/xml; charset=UTF-8
Server: WorldBank
Web Server2
Date: Sat, 22 Mar 2014 00:43:30 GMT
X-Cache: MISS from transproxy
Via: 1.1
transproxy (squid)
Connection: keep-alive

Body:
<?xml version="1.0" encoding="utf-8"?>
<wb:countries page="1" pages="1" per_page="50" total="1"
xmlns:wb="http://www.worldbank.org">
  <wb:country id="FRA">
<wb:iso2Code>FR</wb:iso2Code>
    <wb:name>France</wb:name>
    <wb:region id="ECS">Europe
&amp; Central Asia (all income levels)</wb:region>
    <wb:adminregion id="" />
<wb:incomeLevel id="OEC">High income: OECD</wb:incomeLevel>
    <wb:lendingType id="LNX">Not
classified</wb:lendingType>

<wb:longitude>2.35097</wb:longitude>
    <wb:latitude>48.8566</wb:latitude>
</wb:country>
</wb:countries>
```

Example 2: Create GET Methods Using Expressions in the Resource URL

The following example generates a separate GET request for each country code in the input data set. Each code is concatenated into the expression that forms the URL of the resource. Note that the final code, ZZ, is not a valid country code.

```
proc ds2;
data country_codes /overwrite=yes;
dcl char(2) code;
method init();
  code='ES'; output;
  code='FR'; output;
  code='GB'; output;
  code='ZZ'; output; /* unknown country code */
end;
enddata; run; quit;

proc ds2;
data _null_;
  method run();
    declare package http h();
    declare varchar(1024) character set utf8 body;
    declare int rc status;

    /* Build and send a GET method for each country code */
    set country_codes;
    h.createGetMethod('http://api.worldbank.org/countries/'
        || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1990');
```

```
    h.executeMethod();

    /* If the resource was returned by the server, show the response */
    status = h.getStatusCode();     /* get the HTTP status code */
    put 'Country code:' code 'executeMethod() status code:' status;
    if status eq 200 then do;       /* 200 = OK */
      /* retrieve the body from the response that came from the server */
      h.getResponseBodyAsString(body, rc);
      put 'Body:';
      put body;
    end;
    put;
  end;
enddata; run; quit;
```

The following lines are written to the log:

```

Methods:

- "EXECUTEMETHOD Method" on page 1758

- "EXECUTEMETHODSTREAM Method" on page 1759
- "SETURL Method" on page 1781

CREATEHEADMETHOD Method

Creates an HTTP HEAD method to test whether a web resource exists and to retrieve its headers.

Syntax

package.**CREATEHEADMETHOD**{( ) | (*'url'*)};

Required Arguments

package
specifies an instance of the HTTP package variable.

( ) | (*'url'*)
either generates the HTTP HEAD method without a URL or specifies the URL of the resource.

Tip The URL can include query strings (name/value pairs).

Details

Use the CREATEHEADMETHOD method to create an HTTP HEAD method. After you create the HEAD method, call the EXECUTEMETHOD method to send the request to the web server.

The URL must be set either as an argument in the CREATEHEADMETHOD method or by using the SETURL method.

Example

The following example creates a HEAD method, sends the request to the web server, and displays the headers of the response.

```
data _null_;
  method init();
    declare package http h();
    declare varchar(1024) character set utf8 headers;
    declare int rc status;
    declare char(2) code;

    /* Build and send a HEAD method for a resource */
```

```
    code = 'GB';
    h.createHeadMethod('http://api.worldbank.org/countries/'
      || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1990');
    h.executeMethod();

    /* If the resource headers were returned by the server, show them */
    status = h.getStatusCode();   /* get the HTTP status code */
    put 'Country code:' code 'executeMethod() status:' status;
    if status eq 200 then do;     /* 200 = OK */
      /* retrieve the headers from the response that came from the server */
      h.getResponseHeadersAsString(headers, rc);
      put 'Headers:';
      put headers;
    end;
  end;
enddata; run;
```

The following lines are written to the log:

```
Country code: GB executeMethod() status: 200
Headers:
HTTP/1.1 200 OK
Content-Length: 0
Content-Type: text/xml; charset=UTF-8
Server: WorldBank Web
Server1
Date: Tue, 25 Mar 2014 21:05:48 GMT
X-Cache: MISS from transproxy
Via: 1.1 transproxy
(squid)
Connection: keep-alive
```

- "SETURL Method" on page 1781

CREATEPATCHMETHOD Method

Creates an HTTP PATCH method to request the web server to accept data for a resource.

Note: CREATEPATCHMETHOD is new beginning in 2026.08.

Syntax

package.**createPatchMethod**{( ) | (*'url'*)'};

Required Arguments

package
specifies an instance of the HTTP package variable.

( ) | *('url')*
generates the HTTP PATCH method without a URL or specifies the URL of the resource.

Tip The URL can include query strings (name/value pairs).

Details

The CREATEPATCHMETHOD method creates an HTTP PATCH method.

The URL must be set either as an argument in the CREATEPATCHMETHOD method or by using the SETURL method.

Because the PATCH method requires a body, complete the PATCH method by doing the following:

- Add the body content by calling one of the SETREQUESTBODY* methods, depending on the content type.
- Indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the Content-Type: header.

Then, call the EXECUTEMETHOD method to send the request to the web server.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

CREATEPOSTMETHOD Method

Creates an HTTP POST method to request the web server to accept data for a resource.

Syntax

package.**CREATEPOSTMETHOD** {( ) | (*'url'*)};

Required Arguments

package
specifies an instance of the HTTP package variable.

( ) | (*'url'*)
either generates the HTTP POST method without a URL or specifies the URL of the resource.

Tip The URL can include query strings (name/value pairs).

Details

Use the CREATEPOSTMETHOD method to create an HTTP POST method.

The URL must be set either as an argument in the CREATEPOSTMETHOD method or by using the SETURL method.

Because the POST method requires a body, complete the POST method by doing the following:

- Add the body content by calling one of the SETREQUESTBODY* methods, depending on the content type.
- Indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the `Content-Type:` header.

Then, call the EXECUTEMETHOD method to send the request to the web server.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

- "SETREQUESTBODYASSTRING Method" on page 1776
- "SETREQUESTCONTENTTYPE Method" on page 1778
- "SETURL Method" on page 1781

CREATEPUTMETHOD Method

Creates an HTTP PUT method to request the web server to accept data for a resource.

Note: CREATEPUTMETHOD is new beginning in 2026.08.

Syntax

package.**createPutMethod** {( ) | ('*url*)'};

Required Arguments

package
specifies an instance of the HTTP package variable.

( ) | *('url')*
generates the HTTP PUT method without a URL or specifies the URL of the resource.

Tip The URL can include query strings (name/value pairs).

Details

The CREATEPUTMETHOD method creates an HTTP PUT method.

The URL must be set either as an argument in the CREATEPUTMETHOD method or by using the SETURL method.

Because the PUT method requires a body, complete the PUT method by doing the following:

- Add the body content by calling one of the SETREQUESTBODY* methods, depending on the content type.
- Indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the Content-Type: header.

Then, call the EXECUTEMETHOD method to send the request to the web server.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

DECLARE PACKAGE Statement: HTTP Package

Creates a package variable and enables you to create an instance of the HTTP package.

Category: Local

Note: The DS2 HTTP package is subject to SAS LOCKDOWN option restrictions. For more information, see "LOCKDOWN" in *SAS Programmer's Guide: Essentials*.

Tip: The PACKAGE statement is not required for an HTTP package.

Syntax

DECLARE PACKAGE HTTP *variable*( );

Required Argument

variable
specifies a variable that can reference an instance of the HTTP package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use an HTTP package to construct an HTTP client to access HTTP web servers. The HTTP package is predefined for DS2 programs.

You declare an HTTP package by using the DECLARE PACKAGE statement. When a package is declared, a variable is created that can reference an instance of the package. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of an HTTP package:

- Use the DECLARE PACKAGE statement along with the _NEW_ operator:

```
declare package http httpclt;
httpclt = _new_ http();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package http httpclt();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

Operators:

- "_NEW_ Operator: HTTP Package" on page 1769

DELETE Method: HTTP Package

Deletes an HTTP package instance and frees its resources.

Note: The DELETE method is not required. When no HTTP package variables reference an HTTP package instance, the package instance is automatically deleted.

Syntax

package.**DELETE**( );

Required Argument

package
specifies the name of the HTTP package variable.

Details

When you no longer need the HTTP package, delete it by using the DELETE method. If you attempt to use an HTTP package instance after you delete it, an error is written to the log.

See Also

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

EXECUTEMETHOD Method

Executes the HTTP method and enables retrieval of the response body as a complete entity.

Syntax

package.**EXECUTEMETHOD**( );

Required Argument

package
specifies an instance of the HTTP package variable.

Details

You must create a GET, HEAD, or POST method before you call the EXECUTEMETHOD method to send the request to the web server. The EXECUTEMETHOD method sends the last method that was created.

If the response has a body, the response body must be retrieved as an entire entity by using one of the GETRESPONSEBODYAS* methods.

Note: The EXECUTEMETHOD method does not support streaming of the response body. If you use one of the STREAMRESPONSEBODYAS* methods to retrieve the response body after sending the request with the EXECUTEMETHOD method, a run-time error occurs. Use the EXECUTEMETHODSTREAM method instead.

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "EXECUTEMETHODSTREAM Method" on page 1759
- "GETSTATUSCODE Method" on page 1767
- "GETRESPONSECONTENTTYPE Method" on page 1764
- "GETRESPONSEBODYASBINARY Method" on page 1761
- "GETRESPONSEBODYASSTRING Method" on page 1762
- "SETSOCKETTIMEOUT Method" on page 1780

EXECUTEMETHODSTREAM Method

Executes the HTTP method and enables streaming of the response body from the HTTP server.

Syntax

package.**EXECUTEMETHODSTREAM**( );

Required Argument

package
specifies an instance of the HTTP package variable.

Details

Use the EXECUTEMETHODSTREAM method when you want to stream the response body from the web server in chunks, using either the STREAMRESPONSEBODYASBINARY or STREAMRESPONSEBODYASSTRING method. This is useful when you want to process the response without waiting for all of the data to arrive from the server.

You must create a GET method before you call the EXECUTEMETHODSTREAM method to send the request to the web server. The EXECUTEMETHODSTREAM method sends the last method that was created.

Note: The EXECUTEMETHODSTREAM method does not support retrieval of the response body as an entire entity. If you use one of the GETRESPONSEBODYAS* methods to retrieve the response body after sending the request with the EXECUTEMETHODSTREAM method, a run-time error occurs. Use the EXECUTEMETHOD method instead.

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "EXECUTEMETHOD Method" on page 1758
- "GETSTATUSCODE Method" on page 1767
- "GETRESPONSECONTENTTYPE Method" on page 1764
- "SETSOCKETTIMEOUT Method" on page 1780
- "STREAMRESPONSEBODYASBINARY Method" on page 1783
- "STREAMRESPONSEBODYASSTRING Method" on page 1784

GETRESPONSEBODYASBINARY Method

Returns the entire body from the HTTP response in binary format.

Restriction: If you use the GETRESPONSEBODYASBINARY method to return the entire body from the HTTP response in binary format, you cannot use the SETRESPONSEBODYCHARACTERSET method.

Syntax

package.**GETRESPONSEBODYASBINARY**(*variable*, *rc*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the binary variable to hold the entire response body.

rc
specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the GETRESPONSEBODYASBINARY method to retrieve the response body in binary format. The response body is returned as one entity.

You can call the GETRESPONSEBODYASBINARY method after using the EXECUTEMETHOD method to retrieve the response body returned by the web server.

Note: The GETREAPONSEBODYASBINARY method does not return until the web client has received all the data from the web server.

Note: The response body is not transcoded.

Note: The EXECUTEMETHOD method does not support streaming of the response body.

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "CREATEGETMETHOD Method" on page 1747
- "EXECUTEMETHOD Method" on page 1758
- "GETRESPONSEBODYASSTRING Method" on page 1762
- "SETRESPONSEBODYCHARACTERSET Method" on page 1779

GETRESPONSEBODYASSTRING Method

Returns the entire body from the HTTP response in character string format.

Requirement: A character set for the response body must not be set after getting the response body. A character set for the response body must be specified with the SETRESPONSEBODYCHARACTERSET method before getting the response body with the GETRESPONSEBODYASSTRING method.

Syntax

package.**GETRESPONSEBODYASSTRING**(*variable*, *rc*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the variable to hold the entire response body.

rc
specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the GETRESPONSEBODYASSTRING method to retrieve the response body in character string format. The response body is returned as one entity.

If the content type is not set, the HTTP client deduces a character set from the response content type. If the HTTP client is unable to deduce a character set from the response content type, the character set defaults to UTF-8. However, you can use the SETRESPONSEBODYCHARACTERSET method to specify the character set to use when retrieving the response body.

You can call the GETRESPONSEBODYASSTRING method after using the EXECUTEMETHOD method to retrieve the response body returned by the web server.

Note: The GETREAPONSEBODYASSTRING method does not return until the web client has received all the data from the web server.

Note: The response body is transcoded to the encoding of the string if the encodings are different.

Note: The EXECUTEMETHOD method does not support streaming of the response body.

Example

```
data _null_;
  method init();
    declare package http h();
    declare varchar(1024) character set utf8 body;
    declare int rc status;
    declare char(2) code;

    /* Build and send a GET method for a resource */
    code = 'FR';
    h.createGetMethod('http://api.worldbank.org/countries/'
      || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1991');
    h.executeMethod();

    /* If the resource was returned by the server, show the response */
    status = h.getStatusCode();   /* get the HTTP status code */
    put 'Requested resource for country code:' code 'executeMethod() status:' status;
    if status eq 200 then do;     /* 200 = OK */
      /* retrieve the body from the response that came from the server */
      h.getResponseBodyAsString(body, rc);
      put 'Body:';
      put body;
    end;
  end;
enddata; run;
```

The following lines are written to the log.

```
Requested resource for country code: FR executeMethod() status: 200
Body:
<?xml version="1.0" encoding="utf-8"?>
<wb:data page="1" pages="1" per_page="50" total="2"
xmlns:wb="http://www.worldbank.org">
  <wb:data>
    <wb:indicator id="NY.GNP.PCAP.CD">GNI per
capita, Atlas method (current US$)</wb:indicator>
    <wb:country id="FR">France</wb:country>
   <wb:date>1991</wb:date>
    <wb:value>20880</wb:value>
    <wb:decimal>0</wb:decimal>
</wb:data>
  <wb:data>
    <wb:indicator id="NY.GNP.PCAP.CD">GNI per capita, Atlas method
(current US$)</wb:indicator>
    <wb:country id="FR">France</wb:country>
<wb:date>1990</wb:date>
    <wb:value>20050</wb:value>
    <wb:decimal>0</wb:decimal>
</wb:data>
</wb:data>
```

- "GETRESPONSEBODYASBINARY Method" on page 1761
- "SETRESPONSEBODYCHARACTERSET Method" on page 1779

GETRESPONSECONTENTTYPE Method

Returns the content type from the HTTP response.

Syntax

content-type-variable=*package*.**GETRESPONSECONTENTTYPE**( );

Required Arguments

content-type-variable
specifies the variable to hold the content type value of the HTTP response.

Note: Consult an HTTP reference for a list of possible content types.

package
specifies an instance of the HTTP package.

Details

Use the GETRESPONSECONTENTTYPE method to retrieve the content type from the latest response message.

Example

```
data _null_;
  method init();
    declare package http h();
    declare varchar(1024) character set utf8 body contentType headers;
    declare int rc status;

    /* Build and send a HEAD method for the 'ES' resource */
    h.createHeadMethod('http://api.worldbank.org/countries/ES');
    h.executeMethod();

    /* If the resource was returned by the server, show the response */
    status = h.getStatusCode();   /* get the HTTP status code */
    put 'Country code: ES, executeMethod() status:' status;
    if status eq 200 then do;     /* 200 = OK */
      /* retrieve the content type from the response that came from the server */
      contentType = h.getResponseContentType();
      put 'Content type:' contentType;
    end;
  end;
enddata; run;
```

The following lines are written to the log.

```
Country code: ES, executeMethod() status: 200
Content type: text/xml; charset=UTF-8
```

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "EXECUTEMETHOD Method" on page 1758
- "EXECUTEMETHODSTREAM Method" on page 1759

GETRESPONSEHEADERSASSTRING Method

Returns the response headers from the HTTP method in character string format.

Syntax

package.**GETRESPONSEHEADERSASSTRING**(*variable*, *rc*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the variable to hold the response headers.

rc
specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the GETRESPONSEHEADERSASSTRING method to retrieve all headers from the HTTP response. You can use the GETRESPONSEHEADERSASSTRING method after using either the EXECUTEMETHOD method or the EXECUTEMETHODSTREAM method to send any HTTP request to the server.

Example

The following example creates and sends a HEAD method and uses the GETRESPONSEHEADERSASSTRING method to display the headers of the response from the web server.

```
data _null_;
  method init();
    declare package http h();
    declare varchar(1024) character set utf8 headers;
    declare int rc status;
    declare char(2) code;

    /* Build and send a HEAD method for a resource */
```

```
    code = 'GB';
    h.createHeadMethod('http://api.worldbank.org/countries/'
      || code || '/indicators/NY.GNP.PCAP.CD/?date=1990:1990');
    h.executeMethod();

    /* If the resource headers were returned by the server, show them */
    status = h.getStatusCode();   /* get the HTTP status code */
    put 'Country code:' code 'executeMethod() status:' status;
    if status eq 200 then do;     /* 200 = OK */
      /* retrieve the headers from the response that came from the server */
      h.getResponseHeadersAsString(headers, rc);
      put 'Headers:';
      put headers;
    end;
  end;
enddata; run;
```

The following lines are written to the log:

```
Country code: GB executeMethod() status: 200
Headers:
HTTP/1.1 200 OK
Content-Length: 0
Content-Type: text/xml; charset=UTF-8
Server: WorldBank Web
Server1
Date: Tue, 25 Mar 2014 21:05:48 GMT
X-Cache: MISS from transproxy
Via: 1.1 transproxy
(squid)
Connection: keep-alive
```

GETSTATUSCODE Method

Returns the HTTP status code from the most recently executed HTTP method.

Syntax

status-code-variable=*package*.**GETSTATUSCODE**( );

Required Arguments

status-code-variable
specifies the variable to hold the HTTP status code value.

Note: Consult an HTTP reference for possible status codes.

package
specifies an instance of the HTTP package variable.

Details

Use the GETSTATUSCODE method to retrieve the HTTP status code from the most recently executed HTTP method.

Example

```
data _null_;
  method init();
    declare package http h();
    declare int status;

    /* Build and send a HEAD method for a resource */
    h.createHeadMethod('http://support.sas.com/documentation/');
    h.executeMethod();

    /* If the resource was returned by the server, show the response */
    status = h.getStatusCode();   /* get the HTTP status code */
    put 'HEAD method created for resource:';
    put 'http://support.sas.com/documentation/';
    put 'executeMethod() status:' status;
  end;
enddata; run;
```

The following lines are written to the log.

```
HEAD method created for resource:
http://support.sas.com/documentation/
executeMethod() status: 200
```

NEW Operator: HTTP Package

Constructs an instance of an HTTP package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable=**_NEW_ HTTP**( );

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare an HTTP package variable using the DECLARE PACKAGE statement. After you declare an HTTP package variable, use the _NEW_ operator to instantiate an instance of the HTTP package and assign the new package instance to the HTTP package variable.

```
declare package http h;
h = _new_ http();
```

As an alternative to the two-step process of using the DECLARE PACKAGE statement and the _NEW_ operator to declare and instantiate an HTTP package, you can declare and instantiate a package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package http h();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Statements:

- "DECLARE PACKAGE Statement: HTTP Package" on page 1757
- "PACKAGE Statement" on page 1406

SETOAUTHTOKEN Method

Specifies a string that contains the OAuth access token for the request.

Syntax

package.**SETOAUTHTOKEN**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the string variable that contains the OAuth access token.

Details

Open Authorization (OAuth) is an open standard for token-based authentication and authorization on the internet. OAuth is designed to work with HTTP and allows access tokens to be issued to third-party clients by an authorization server, with the approval of the resource owner. The third-party client then uses the access token to access the protected resources that are hosted by the resource server.

For the HTTP package, use the SETOAUTHTOKEN method to provide the OAuth access token that are added to the request header as a Bearer value of an Authorization header field.

For more information about OAuth, see OAuth 2.0.

Comparisons

You provide the OAuth access token with the SETOAUTHTOKEN method. You allow SAS to search the environment for an OAuth access token with the ADDSASOAUTHTOKEN method.

See Also

Methods:

- "ADDSASOAUTHTOKEN Method" on page 1746

SETPASSWORD Method

Specifies the string that represents the password associated with the specified user name.

Syntax

package.**SETPASSWORD**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the string variable that contains the password.

Details

If the URL that you specify with the SETURL method requires a password, specify it with the SETPASSWORD method. Likewise, if the URL requires a user name, specify it with the SETUSERNAME method.

Comparisons

The SETPASSWORD method specifies the password of the non-proxy user name. The SETPROXYPASSWORD method specifies the password of the proxy user name.

See Also

Methods:

- “SETPROXYPASSWORD Method” on page 1772
- “SETURL Method” on page 1781
- “SETUSERNAME Method” on page 1782

SETPROXYPASSWORD Method

Specifies the string that represents the password associated with the specified proxy user name.

Syntax

package.**SETPROXYPASSWORD**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the string variable that contains the password.

Details

If the proxy URL that you specify with the SETPROXYURL method requires a password, specify it with the SETPROXYPASSWORD method. Likewise, if the proxy URL requires a user name, specify it with the SETPROXYUSERNAME method.

Comparisons

The SETPROXYPASSWORD method specifies the password of the proxy user name. The SETPASSWORD method specifies the password of the non-proxy user name.

See Also

Methods:

- "SETPASSWORD Method" on page 1771
- "SETPROXYURL Method" on page 1773
- "SETPROXYUSERNAME Method" on page 1774

SETPROXYURL Method

Specifies the proxy URL to which the HTTP client should connect.

Syntax

package.**SETPROXYURL**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the variable that contains the proxy URL to which the HTTP client should connect.

Details

The SETPROXYURL method enables you to specify a proxy URL to which the HTTP client should connect. A proxy URL is a web address to access a proxy server through a web browser.

Comparisons

The SETPROXYURL specifies a proxy URL. The SETURL specifies a URL.

See Also

Methods:

- "SETPROXYPASSWORD Method" on page 1772

- "SETPROXYUSERNAME Method" on page 1774
- "SETURL Method" on page 1781

SETPROXYUSERNAME Method

Specifies the string that represents the domain-qualified user name of the user who is attempting to connect to the specified proxy URL.

Syntax

package.**SETPROXYUSERNAME**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the variable that contains the domain-qualified user name.

Details

If the proxy URL that you specify with the SETPROXYURL method requires a user name, specify it with the SETPROXYUSERNAME method. Likewise, if the proxy URL requires a password, specify it with the SETPROXYPASSWORD method.

Comparisons

The SETPROXYUSERNAME specifies the domain-qualified user name of the user who attempts to connect to the specified proxy URL. The SETUSERNAME specifies the domain-qualified user name of the user who attempts to connect to the specified URL.

See Also

Methods:

- "SETPROXYPASSWORD Method" on page 1772
- "SETURL Method" on page 1781

- “SETUSERNAME Method” on page 1782

SETREQUESTBODYASBINARY Method

Adds the specified body to the HTTP method request in binary format.

Restriction: If you use the SETREQUESTBODYASBINARY method to return the entire body in binary format, you cannot use the SETREQUESTBODYCHARACTERSET method.

Syntax

package.**SETREQUESTBODYASBINARY**(*variable*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the binary variable that contains the request body data.

Details

Use the SETREQUESTBODYASBINARY method to add the request body, in binary format, to the HTTP method.

To complete the HTTP method, indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the `Content-Type:` header. Then, call the EXECUTEMETHOD method to send the request to the web server.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

See Also

- “Using the HTTP Package” in *SAS DS2 Programmer’s Guide*

Methods:

- “ADDREQUESTHEADER Method” on page 1745
- “CREATEPOSTMETHOD Method” on page 1754
- “EXECUTEMETHOD Method” on page 1758

SETREQUESTBODYASSTRING Method

Adds the specified body to the HTTP method request in character string format.

Requirement: A character set for the request body must not be specified after setting the request body. A character set for encoding the request body must be specified with the SETREQUESTBODYCHARACTERSET method before setting the request body with the SETREQUESTBODYASSTRING method.

Syntax

package.**SETREQUESTBODYASSTRING**(*variable*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the string variable that contains the request body data.

Details

Use the SETREQUESTBODYASSTRING method to add the request body, in character string format, to the HTTP method.

To complete the HTTP method, indicate the content type of the body by calling the SETREQUESTCONTENTTYPE method, which sets the `Content-Type:` header. Then, call the EXECUTEMETHOD method to send the request to the web server.

If the content type is not set, the HTTP client deduces a character set from the request content type. If the HTTP client is unable to deduce a character set from the request content type, the character set defaults to UTF-8. However, you can use the SETREQUESTBODYCHARACTERSET method to specify the character set to use when encoding the request body.

Note: The content length is computed by the DS2 HTTP client after transcoding the data.

Note: If the encoding of the provided request data differs from the specified content type, the data is transcoded to the encoding that is specified by content type.

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "ADDREQUESTHEADER Method" on page 1745
- "CREATEPOSTMETHOD Method" on page 1754
- "EXECUTEMETHOD Method" on page 1758
- "SETREQUESTBODYASBINARY Method" on page 1775
- "SETREQUESTBODYCHARACTERSET Method" on page 1777
- "SETREQUESTCONTENTTYPE Method" on page 1778

SETREQUESTBODYCHARACTERSET Method

Specifies the character set to use when encoding the request body.

Restriction: If you use the SETREQUESTBODYASBINARY method to return the entire body in binary format, you cannot use the SETREQUESTBODYCHARACTERSET method.

Requirement: A character set for the request body must not be specified after setting the request body. A character set for encoding the request body must be specified with the SETREQUESTBODYCHARACTERSET method before setting the request body with the SETREQUESTBODYASSTRING method.

Syntax

package.**SETREQUESTBODYCHARACTERSET**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the string variable that contains the character set specification.

See For a complete list of character set encoding values, see "Encoding Values in SAS Language Elements" in the *SAS National Language Support (NLS): Reference Guide*.

Details

If you do not specify the character set for encoding the request body, the HTTP client deduces a character set from the request content type. If the HTTP client is unable to deduce a character set from the request content type, the character set defaults to UTF-8.

See Also

Methods:

- "SETREQUESTBODYASBINARY Method" on page 1775
- "SETREQUESTBODYASSTRING Method" on page 1776
- "SETRESPONSEBODYCHARACTERSET Method" on page 1779

SETREQUESTCONTENTTYPE Method

Specifies the content type of the body of the HTTP method request.

Syntax

package.**SETREQUESTCONTENTTYPE**(*content-type*);

Required Arguments

content-type
specifies the variable that contains the content type value.

Note: Consult an HTTP reference for possible content types.

package
specifies an instance of the HTTP package variable.

Details

Use the SETREQUESTCONTENTTYPE method to specify the content type of the body of the HTTP method.

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "CREATEPOSTMETHOD Method" on page 1754
- "EXECUTEMETHOD Method" on page 1758
- "SETREQUESTBODYASBINARY Method" on page 1775
- "SETREQUESTBODYASSTRING Method" on page 1776

SETRESPONSEBODYCHARACTERSET Method

Specifies the character set to use when decoding the response body.

Restriction: If you use the GETRESPONSEBODYASBINARY method to return the entire body from the HTTP response in binary format, you cannot use the SETRESPONSEBODYCHARACTERSET method.

Requirement: A character set for the response body must not be set after getting the response body. A character set for the response body must be specified with the SETRESPONSEBODYCHARACTERSET method before getting the request body with the GETRESPONSEBODYASSTRING method.

Syntax

package.**SETRESPONSEBODYCHARACTERSET**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the string variable that contains the character set specification.

See For a complete list of character set encoding values, see "Encoding Values in SAS Language Elements" in the *SAS National Language Support (NLS): Reference Guide*.

Details

If you do not specify the character set for encoding the response body, the HTTP client deduces a character set from the response content type. If the HTTP client is unable to deduce a character set from the response content type, the character set defaults to UTF-8.

See Also

Methods:

- "GETRESPONSEBODYASBINARY Method" on page 1761
- "GETRESPONSEBODYASSTRING Method" on page 1762
- "SETREQUESTBODYCHARACTERSET Method" on page 1777

SETSOCKETTIMEOUT Method

Specifies the socket time-out value to wait for a response from an HTTP web server.

Syntax

package.**SETSOCKETTIMEOUT**(*time-out-value*);

Required Arguments

package
specifies an instance of the HTTP package variable.

time-out-value
specifies the default socket time-out, in milliseconds, to wait for a response from the web server.

Details

Use the SETSOCKETTIMEOUT method to specify how long to wait for a response from the web server.

The SETSOCKETTIMEOUT method can be set for each new CREATE method when the default time-out is too long or too short.

Example

The following example sets the socket time-out value.

```
data _null_;
   method init();
      declare package http h();
      declare int status_code rc;

      /* get method call with 10 second delay */
      rc = h.createGetMethod('http://httpbin.org/delay/10');
      if (rc ne 0) then put 'TEST ERROR:' rc=;

      /* set 5 second timeout -- execute should timeout */
      rc = h.setSocketTimeout(5000);
      if (rc ne 0) then put 'TEST ERROR:' rc=;
      rc = h.executeMethod();
      if (rc eq 0) then put 'TEST ERROR:' rc=;
   end;
enddata;
run;
```

See Also

"Using the HTTP Package" in *SAS DS2 Programmer's Guide*

SETURL Method

Specifies the URL to which the HTTP client should connect.

Syntax

package.**SETURL**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the variable that contains the URL to which the HTTP client should connect.

Details

The SETURL method enables you to specify a URL to which the HTTP client should connect.

In order to use a URL that is set in the client, you must use the version of the CREATEGETMETHOD, CREATEHEADMETHOD, and CREATEPOSTMETHOD methods that accepts no arguments.

Here is an example of how the SETURL method is used:

```
h.createGetMethod();
h.setURL('http://httpbin.org/get');
```

Comparisons

The SETURL specifies a URL. The SETPROXYURL specifies a proxy URL.

See Also

Methods:

- “CREATEGETMETHOD Method” on page 1747
- “CREATEHEADMETHOD Method” on page 1752
- “CREATEPOSTMETHOD Method” on page 1754
- “SETPROXYURL Method” on page 1773
- “SETUSERNAME Method” on page 1782
- “SETPASSWORD Method” on page 1771

SETUSERNAME Method

Specifies the string that represents the domain-qualified user name of the user who is attempting to connect to the specified URL.

Syntax

package.**SETUSERNAME**('*variable*');

Required Arguments

package
specifies an instance of the HTTP package variable.

'variable'
specifies the string variable that contains the domain-qualified user name.

Details

If the URL that you specify with the SETURL method requires a user name, specify it with the SETUSERNAME method. Likewise, if the URL requires a password, specify it with the SETPASSWORD method.

Comparisons

The SETUSERNAME method specifies the domain-qualified user name of the user who attempts to connect to the specified URL. The SETPROXYUSERNAME method specifies the domain-qualified user name of the user who attempts to connect to the specified proxy URL.

See Also

Methods:

- “SETPASSWORD Method” on page 1771
- “SETURL Method” on page 1781

STREAMRESPONSEBODYASBINARY Method

Streams the body, in chunks, from the HTTP response in binary format.

Syntax

package.**STREAMRESPONSEBODYASBINARY**(*variable*, *rc*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the variable that will contain the response data chunk.

rc
specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the STREAMRESPONSEBODYASBINARY method to retrieve the response body in binary format. The response body is streamed, in chunks.

You can call the STREAMRESPONSEBODYASBINARY method after using the EXECUTEMETHODSTREAM method.

If you do not want to complete the streaming of the body data, call the ABORT method to stop the execution of the method.

Note: The EXECUTEMETHODSTREAM method does not support retrieval of the response body as one entity.

See Also

- "Using the HTTP Package" in *SAS DS2 Programmer's Guide*

Methods:

- "ABORT Method" on page 1744
- "EXECUTEMETHODSTREAM Method" on page 1759
- "STREAMRESPONSEBODYASSTRING Method" on page 1784

STREAMRESPONSEBODYASSTRING Method

Streams the body, in chunks, from the HTTP response in character string format.

Applies to: HTTP package

Syntax

package.**STREAMRESPONSEBODYASSTRING**(*variable*, *rc*);

Required Arguments

package
specifies an instance of the HTTP package variable.

variable
specifies the variable that will contain the response data chunk.

rc
specifies the variable to hold the return code value.

Note: A return code value of 0 indicates success; a value of 1 indicates failure.

Details

Use the STREAMRESPONSEBODYASSTRING method to retrieve the response body in character string format. The response body is streamed, in chunks.

You can call the STREAMRESPONSEBODYASBINARY method after using the EXECUTEMETHODSTREAM method.

If you do not want to complete the streaming of the body data, call the ABORT method to stop the execution of the method.

Note: The EXECUTEMETHODSTREAM method does not support retrieval of the response body as one entity.

DS2 JSON Package Methods, Operators, and Statements

Dictionary

CREATEPARSER Method

Creates a JSON Parser instance.

Syntax

Form 1: *package*.**CREATEPARSER** ( );

Form 2: *package*.**CREATEPARSER** (*json-text*, *tipping-size*);

Form 3: *package*.**CREATEPARSER** (*json-text*);

Form 4: *package*.**CREATEPARSER** (*tipping-size*);

Required Arguments

package
specifies an instance of the JSON package.

json-text
specifies the input JSON text to be parsed.

Data type NCHAR, NVARCHAR

tipping-size
specifies the minimum number of characters of output JSON text to accumulate before calling the string call-back routine for strings longer than *tipping-size*.

Default 0, which indicates that only complete strings are returned to the string callback, regardless of length.

Restriction The maximum number of characters that can be returned is (*tipping-size* + 4) when *tipping-size* is set.

Data type INTEGER

Details

If you use Form 1 or Form 4 of the CREATEPARSER method syntax, you should subsequently call the SETPARSERINPUT method to provide the JSON text to be parsed.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "DESTROYPARSER Method" on page 1792
- "SETPARSERINPUT Method" on page 1808

CREATEWRITER Method

Creates a JSON writer instance.

Syntax

package.**CREATEWRITER** ([PRETTY]);

Required Argument

package
specifies an instance of the JSON package.

Optional Argument

PRETTY
creates a more human-readable format that uses indention to illustrate the JSON container structure. Otherwise, the output is written in a single line.

Data type NVARCHAR

Note More flags might be available in future releases.

Details

The DS2 JSON package's writer currently does not support streaming. Instead, the Write instances are gathered in memory until retrieved by calling the WRITERGETTEXT method.

Example

For an example, see "WRITEARRAYOPEN Method" on page 1809.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "DESTROYWRITER Method" on page 1793
- "WRITERGETTEXT Method" on page 1818

DECLARE PACKAGE Statement: JSON Package

Creates a package variable and enables you to create an instance of the JSON package.

Category: Local

Syntax

DECLARE PACKAGE JSON *variable*( );

Required Argument

variable
specifies a name that can reference an instance of the JSON package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a JSON package to create and parse JSON text. The JSON package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a JSON package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package json j;
j = _new_ json();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package json j();
```

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: JSON Package" on page 1807

DELETE Method: JSON Package

Deletes a JSON package.

Syntax

package.**DELETE**( );

Required Argument

package
specifies an instance of the JSON package variable.

Details

When you no longer need the JSON package, delete it by using the DELETE method. The DELETE method is not required. When a JSON package's reference count drops to zero, the package is automatically deleted.

Note: It is possible to write DS2 code to create circular references such that the reference count might never drop to zero. In that case, the instance lives until the end of the RUN block unless it is explicitly deleted using the DELETE method. Here is an example of how to create a circular reference in DS2:

```
proc ds2;
package e / overwrite=yes;
   dcl package e next;
   dcl package e prev;

   method setnext(package e e);
      next = e;
   end;

   method setprev(package e e);
      prev = e;
   end;
endpackage;

data _null_;
   dcl package e e1();
   dcl package e e2();

   method init();
      e1.setnext(e2);
      e2.setprev(e1);
   end;
enddata;
run;
quit;
```

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

DESTROYPARSER Method

Destroys a JSON Parser instance.

Syntax

package.**DESTROYPARSER** ( );

Required Argument

package
specifies an instance of the JSON package.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "CREATEPARSER Method" on page 1788

DESTROYWRITER Method

Destroys a JSON writer instance.

Syntax

package.**DESTROYWRITER** ( );

Required Argument

package
specifies an instance of the JSON package.

Example

For an example, see "WRITEARRAYOPEN Method" on page 1809.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

■ "CREATEWRITER Method" on page 1789

GETNEXTTOKEN Method

Returns the next validated JSON language item or element from the JSON text.

Syntax

Form 1: *package*.**GETNEXTTOKEN** (*rc*, *token-type*, *parse-flags*);

Form 2: *package*.**GETNEXTTOKEN** (*rc*, *token*, *token-type*, *parse-flags*);

Form 3: *package*.**GETNEXTTOKEN** (*rc*, *token*, *token-type*, *parse-flags*, *line-number*, *column-number*);

Required Arguments

package
specifies an instance of the JSON package.

rc
specifies the variable to hold the return code value. Possible return code values are as follows:

0 Success

100 The output token argument's maximum length was not large enough and truncation occurred.

101 Done. Depending on the use case, this might or might not be expected.

300 End of text. Depending on the use case, this might or might not be expected.

301 An error occurred while parsing the text.

Data type INTEGER

token-type
specifies the variable to hold the type of token to look for. *Token-type* can be one of the following values:

4 Boolean true

8 Boolean false

16 Left bracket ([ )

32 Right bracket ( ])

64 Left brace ({)

128 Right brace (})

256 String

512 Numeric

1024 Null

Data type INTEGER

parse-flags

specifies the variable to store an output flag set provided by the JSON processor's parser. When the token being parsed is a string, valid output values are as follows:

1 token is a label in an object

2 token is incomplete

3 token is a label in an object and is incomplete

When the token being parsed is numeric, valid values are as follows:

3 token is an integral numeric

4 token is a floating point number

Data type INTEGER

token

specifies the variable to hold the next token or string.

Data type CHAR

line-number

specifies the variable to hold the line number within the text where the token is located.

Data type BIGINT

Tip You can use the line number to help determine the location of the token within the text.

column-number

specifies the variable to hold the column number within the text where the token is located.

Data type BIGINT

Tip You can use the column number to help determine the location of the token within the text.

Details

With the exception of *parseFlags*, all of the arguments to the GETNEXTTOKEN method are IN_OUT arguments. They are used to return a value to the caller of the GETNEXTTOKEN method. The values are passed by reference.

You can use the CREATEPARSER method to provide the input JSON text. You can use the IS* methods to test the token type. Or, you can use an IF expression to associate *token* with a string value. For an example of how the GETNEXTTOKEN method can be used, see "Example: Using an HTTP and JSON Package to Extract and Parse a REST-Formatted File" on page 2231.

ISBOOLEANFALSE Method

Returns true if the token is false.

Syntax

package.**ISBOOLEANFALSE**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISBOOLEANFALSE method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISBOOLEANTRUE Method" on page 1797
- "WRITEBOOLEANFALSE Method" on page 1810

ISBOOLEANTRUE Method

Returns true if the token is true.

Syntax

package.**ISBOOLEANTRUE**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISBOOLEANTRUE method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISBOOLEANFALSE Method" on page 1796
- "WRITEBOOLEANTRUE Method" on page 1811

ISFLOAT Method

Returns true if the token is a floating point number in text form.

Syntax

package.**ISFLOAT**(*token-type*, *parse-flags*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

parse-flags
specifies the parse flags that were obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISFLOAT method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISINTEGER Method" on page 1799
- "ISNUMERIC Method" on page 1803

ISINTEGER Method

Returns true if the token is an integer in text form.

Syntax

package.**ISINTEGER** (*token-type*, *parse-flags*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

parse-flags
specifies the parse flags that were obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISINTEGER method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISFLOAT Method" on page 1798
- "ISNUMERIC Method" on page 1803

ISLABEL Method

Returns true if the token is an object label.

Syntax

package.**ISLABEL**(*token-type*, *parse-flags*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

parse-flags
specifies the parse flags that were obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISLABEL method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794

ISLEFTBRACE Method

Returns true if the token is a left brace ({).

Syntax

package.**ISLEFTBRACE**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISLEFTBRACE method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISRIGHTBRACE Method" on page 1805

ISLEFTBRACKET Method

Returns true if the token is a left bracket ([ ).

Syntax

package.**ISLEFTBRACKET**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
specifies the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISLEFTBRACKET method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISRIGHTBRACKET Method" on page 1806

ISNULL Method

Returns true if the token is null.

Syntax

package.**ISNULL**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
receives the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISNULL method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "WRITENULL Method" on page 1815

ISNUMERIC Method

Returns true if the token is numeric in text form.

Syntax

package.**ISNUMERIC**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
receives the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISNUMERIC method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISFLOAT Method" on page 1798
- "ISINTEGER Method" on page 1799

ISPARTIAL Method

Returns true if the token is incomplete because of tipping.

Syntax

package.**ISPARTIAL**(*parse-flags*);

Required Arguments

package
specifies an instance of the JSON package.

parse-flags
receives the parse flags that were obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISPARTIAL method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794

ISRIGHTBRACE Method

Returns true if the token is a right brace (}).

Syntax

package.**ISRIGHTBRACE**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
receives the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISRIGHTBRACE method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISLEFTBRACE Method" on page 1801

ISRIGHTBRACKET Method

Returns true if the token is a right bracket ( ]).

Syntax

package.**ISRIGHTBRACKET**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
receives the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISRIGHTBRACKET method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Parsing JSON Text" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794
- "ISLEFTBRACKET Method" on page 1801

ISSTRING Method

Returns true if the token is a string.

Syntax

package.**ISSTRING**(*token-type*);

Required Arguments

package
specifies an instance of the JSON package.

token-type
receives the token type that was obtained from the GETNEXTTOKEN method.

Data type INTEGER

Details

You can use the ISSTRING method to test the token type that was obtained from the GETNEXTTOKEN method.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETNEXTTOKEN Method" on page 1794

NEW Operator: JSON Package

Constructs an instance of a JSON package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_ JSON**( );

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a JSON package variable using the DECLARE PACKAGE statement. After you declare a JSON package variable, use the _NEW_ operator to instantiate an instance of the JSON package and assign the new package instance to the JSON package variable.

```
declare package json jsontxt;
jsontxt = _new_ json( );
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a JSON package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package json jsontxt( );
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Statements:

- "DECLARE PACKAGE Statement: JSON Package" on page 1790

SETPARSERINPUT Method

Provides JSON text to the parser when it needs more text.

Restriction: This method is valid only if the parser does not have any text; an error is returned if it does.

Syntax

package.**SETPARSERINPUT**([*json-text*,]);

Required Argument

package
specifies an instance of the JSON package.

Optional Argument

json-text
specifies the JSON text for the parser.

Data type CHAR, VARCHAR, NCHAR, NVARCHAR

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "CREATEPARSER Method" on page 1788

WRITEARRAYOPEN Method

Writes the open bracket ([ ) signifying the beginning of an array.

Syntax

package.**WRITEARRAYOPEN**( );

Required Argument

package
specifies an instance of the JSON package.

Details

The WRITEARRAYOPEN method explicitly opens an array container, which you must explicitly close with the WRITECLOSE method.

Example

The following example creates a writer instance and writes a numeric value to a JSON array container.

```
data _null_;
    method init();
        dcl package json j();
        dcl double dblVal;
        dcl int rc;
        dcl nvarchar(15) jsontxt;

        rc = j.createWriter();
        rc = j.writeArrayOpen();
        dblVal = 12345678.1234;
        rc = j.writeDouble( dblVal,13, 5 );
        rc = j.writeClose();
        j.writerGetText( rc, jsontxt);
        put jsontxt=;
        rc = j.destroywriter();
    end;
enddata;
  run;
```

The following line is written to the SAS log:

```
jsontxt=[1.2346e+07   ]
```

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "WRITECLOSE Method" on page 1811

WRITEBOOLEANFALSE Method

Writes a Boolean false value to the text.

Syntax

package.**WRITEBOOLEANFALSE**( );

Required Argument

package
specifies an instance of the JSON package.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "ISBOOLEANFALSE Method" on page 1796
- "WRITEBOOLEANTRUE Method" on page 1811

WRITEBOOLEANTRUE Method

Writes a Boolean true value to the text.

Syntax

package.**WRITEBOOLEANTRUE**( );

Required Argument

package
specifies an instance of the JSON package.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "ISBOOLEANTRUE Method" on page 1797
- "WRITEBOOLEANFALSE Method" on page 1810

WRITECLOSE Method

Closes the corresponding object (}) or array ( ]).

Syntax

package.**WRITECLOSE**( );

Required Argument

package
specifies an instance of the JSON package.

Details

The WRITECLOSE method closes the most recently opened container of either type that was explicitly opened with the WRITEARRAYOPEN or WRITEOBJOPEN method. You should call the WRITECLOSE method for containers only if you explicitly opened the container with a WRITE*OPEN method.

Example

For an example, see "WRITEARRAYOPEN Method" on page 1809.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "WRITEOBJOPEN Method" on page 1816
- "WRITEARRAYOPEN Method" on page 1809

WRITEDOUBLE Method

Writes a DOUBLE value in text form.

Syntax

Form 1: *package*.**WRITEDOUBLE**(*double-value*);

Form 2: *package*.**WRITEDOUBLE**(*double-value*, *width*);

Form 3: *package*.**WRITEDOUBLE**(*double-value*, *width*, *precision*);

Form 4: *package*.**WRITEDOUBLE**(*double-value*, *width*, *precision*, *options*);

Required Arguments

package
specifies an instance of the JSON package.

double-value
specifies the value to be written.

Data type DOUBLE

width
specifies the width of the formatted value.

Default 0

Data type DOUBLE

precision
indicates the number of digits that appear after the radix character.

Default 15

Data type DOUBLE

options
specifies a flag for formatting. *options* can be one of the following values:

BESTFIT
formats the value using decimal notation in the form of [–]*dddd.ddd* or scientific notation in the form of [–]*d.ddd*e±*dd*. The formatting style depends on the value.

Notes Valid width is 1–32 characters.

Precision is ignored.

BESTFITBIG
formats the value using decimal notation in the form of [–]*dddd.ddd* or scientific notation in the form of [–]*d.ddd*E±*dd*. The formatting style depends on the value.

Notes Valid width is 1–32 characters.

Precision is ignored.

SASBEST
Conforms to the BESTw. format rules. The value is formatted within the specified width. Decimal notation is produced if possible. Otherwise, scientific notation is produced in the style [–]*ddd*.dddE[–]*dd*

Note Trailing zeros after the radix character are suppressed.

SASEW
Conforms to the E*w*. format rules. The value is formatted within the specified width. Scientific notation is always produced in the style [-]*ddd.ddd*E±*dd*.

Notes Valid width is 7–32 characters.

Precision is ignored.

SASEWD
Conforms to the SAS XP Services %*w.d*e rules. The value is formatted within the specified *width*. Scientific notation is always produced in the style [–]*ddd.ddd*E±*dd*.

Notes Valid width is 7–32 digits.

Valid precision is 0–31 digits.

SASWD
Conforms to the *w.d* format rules.

Note The value is formatted within the specified *width*. If *width* is too small, it reverts to the behavior indicated by SASBEST.

DECIMAL
Formats the value using decimal notation in the style [–]*dddd.dd*, using *precision* to determine the number of digits after the radix.

Note The radix character does not appear if there are no digits to display after it or if *precision* is set to zero.

FRACTION
Formats the fractional part of the value in the style of [–]0.*dddd*.

Note The digit before the radix character is always zero.

INTEGER
Formats the fractional part of the value in the style of [–]*dddd*.

Note The fractional part of the value is ignored and no radix character is added to the result.

SNOTE
formats the value using scientific notation in the form of [–]*d.ddd*e±*dd*, using the lowercase 'e' to precede the exponent.

SNOTEBIG
formats the value using scientific notation in the form of [–]*d.ddd*E±*dd*, using the uppercase 'E' to precede the exponent.

Default BESTFIT

Data type CHAR

Example

The following example writes DOUBLE values to an array.

```
data _null_;
    dcl package logger lgr( 'App.tk.D2PKG.JSON' );
    dcl package json j();
    dcl nvarchar(256) matrixA;
    dcl int rc;

    method init();
        rc = j.createWriter();
        rc = j.writeArrayOpen();
        rc = j.writeArrayOpen();
        rc = j.writeDouble(1.1);
        rc = j.writeDouble(1.2);
        rc = j.writeClose();
        rc = j.writeArrayOpen();
        rc = j.writeDouble(2.1);
        rc = j.writeDouble(2.2);
        rc = j.writeClose();
        rc = j.writeClose();
        j.writerGetText( rc, matrixA );
        lgr.log( 4, 'matrix A = $s', matrixA );
        rc = j.destroyWriter();
    end;
enddata;
run;
```

The following lines are written to the SAS log:

```
NOTE: matrix A = [[1.1,1.2],[2.1,2.2]]
```

See Also

"Using the JSON Package" in *SAS DS2 Programmer's Guide*

WRITENULL Method

Writes a null value to the text.

Syntax

package.**WRITENULL**( );

Required Argument

package
specifies an instance of the JSON package.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "ISNULL Method" on page 1802

WRITEOBJOPEN Method

Writes the open brace ({) signifying the beginning of an object.

Syntax

package.**WRITEOBJOPEN**( );

Required Argument

package
specifies an instance of the JSON package.

Details

The WRITEOBJOPEN method explicitly opens an object container, which you must explicitly close with the WRITECLOSE method.

Example

```
proc ds2;
data _null_;
  method init();
    dcl package json j();
    dcl nvarchar(16384) text;
    dcl int rc;

    j.createWriter('PRETTY');
```

```
    j.writeObjOpen();
      j.writeString('TableMetadata');    j.writeObjOpen();
        j.writeString('ColumnMetadata'); j.writeArrayOpen();
          j.writeObjOpen();
            j.writeString('Name');       j.writeString('fname');
            j.writeString('Label');      j.writeString('First Name');
            j.writeString('Type');       j.writeString('VARCHAR');
            j.writeString('Length');     j.writeDouble(256);
          j.writeClose();

          j.writeObjOpen();
            j.writeString('Name');       j.writeString('lname');
            j.writeString('Label');      j.writeString('Last Name');
            j.writeString('Type');       j.writeString('VARCHAR');
            j.writeString('Length');     j.writeDouble(256);
          j.writeClose();

          j.writeObjOpen();
            j.writeString('Name');       j.writeString('dob');
            j.writeString('Label');      j.writeString('Date of
Birth');
            j.writeString('Type');       j.writeString('DATE');
            j.writeString('Length');     j.writeDouble(10);
          j.writeClose();
        j.writeClose();
      j.writeClose();
    j.writeClose();
    j.writerGetText(rc, text);

    put text;
  end;
enddata;
run;
quit;
```

The SAS log returns these results:

```
{
  "TableMetadata": {
    "ColumnMetadata": [
      {
        "Name": "fname",
        "Label": "First Name",
        "Type": "VARCHAR",
        "Length": 256
      },
      {
        "Name": "lname",
        "Label": "Last Name",
        "Type": "VARCHAR",
        "Length": 256
      },
      {
        "Name": "dob",
        "Label": "Date of Birth",
        "Type": "DATE",
        "Length": 10
      }
    ]
  }
}
```

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "WRITECLOSE Method" on page 1811

WRITERGETTEXT Method

Obtains the JSON text that is produced by the writer.

Syntax

package.**WRITERGETTEXT**(*rc*, *json-text*);

Required Arguments

package
specifies an instance of the JSON package.

rc
specifies the variable to hold the return code value. Possible return code values are as follows:

0 Success

100 The output token argument's maximum length was not large enough and truncation occurred.

101 Done. Depending on the use case, this might or might not be expected.

300 End of text. Depending on the use case, this might or might not be expected.

301 A status condition was returned.

Data type INTEGER

json-text
specifies a variable that receives the JSON text.

Data type NVARCHAR

Details

The DS2 JSON package's writer currently does not support streaming. Instead, the Write instances are gathered in memory until retrieved by calling the WRITERGETTEXT method.

Example

For an example, see "WRITEARRAYOPEN Method" on page 1809.

See Also

- "Using the JSON Package" in *SAS DS2 Programmer's Guide*

Methods:

- "CREATEWRITER Method" on page 1789

WRITESTRING Method

Writes a string to the JSON text.

Note: Braces in the syntax convention indicate a syntax grouping.

Syntax

package.**WRITESTRING**({[' | "]}*string*{[' | "]}, *flags*);

Required Arguments

package
specifies an instance of the JSON package.

{['"] }*string*{['"] }
specifies the string to write.

Data type NVARCHAR

Tip The string can be a string literal in single quotation marks, a normal identifier without quotation marks, or a delimited identifier in double quotation marks.

flags
specifies options for special handling of the string. The following values are possible:

0
0 indicates no flags.

16
16 (JSN_SkipScan) indicates that the normal scanning and JSON encoding of the input string should be skipped. This means that either the string is known to contain no invalid or JSON escape characters, or the caller has already performed JSON scanning or encoding on the string. In the latter case, only quotation marks and separators would be inserted with the given string.

For normal scanning, omit the flag so that normal scanning and JSON encoding can proceed.

32
32 (JSN_TrimBlanks) causes the writer to trim trailing blanks from the string.

48
48 causes both the writer to skip scanning and trim blanks.

Data type INTEGER

Example

The following example illustrates different types of string values.

```
data _null_;
    dcl package logger lgr( 'App.tk.D2PKG.JSON' );
    dcl package json j();
    dcl nvarchar(2000) txt;
    dcl varchar(20) "a**b";
    dcl varchar(20) myStr;
```

```
    dcl int rc;

    method init();
        rc = j.createWriter();
        rc = j.writeArrayOpen();
        rc = j.writeString( 'aaaAAA', 0 );
        "a**b" = 'bbbBBB';
        rc = j.writeString( "a**b", 0 );
        myStr = 'cccCCC';
        rc = j.writeString( myStr, 0 );
        rc = j.writeClose();
        j.writerGetText( rc, txt );
        lgr.log( 3, 'txt = $s', txt );
        rc = j.destroyWriter();
    end;
enddata;
run;
```

DS2 Logger Package Methods, Operators, and Statements

Dictionary

DECLARE PACKAGE Statement: Logger Package

Creates a package variable and gives you the option of creating an instance of the logger package.

Category: Local

Tip: The PACKAGE statement is not required for a logger package.

Syntax

DECLARE PACKAGE LOGGER *variable*([*logger-name*]);

Required Argument

variable
specifies a name that can reference an instance of the logger package.

Optional Argument

logger-name
specifies the name of the logger that is defined in the SAS logging facility.

Default SAS root logger

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a logger package to interface with the SAS logging facility. The logger package is predefined for DS2 programs. For more information about the logging facility, see *SAS Viya Logging Facility for SAS Programs and Jobs*.

You declare a logger package by using the DECLARE PACKAGE statement. This associates a logger package with a logger name. After you declare the new logger package, you can send messages to the logger at a specified logging level.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a logger package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package logger logpkg;
logpkg = _new_ logger();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package logger logpkg();
```

For more information about the logger package, see "Using the Logger Package" in *SAS DS2 Programmer's Guide*.

Example

This example creates an instance of a logger package.

```
data _null_;
   dcl package logger l();
```

```
   method init();
      l.log('i', 'Hello World!');
   end;
enddata;
```

See Also

- "Using the Logger Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: Logger Package" on page 1830

DELETE Method: Logger Package

Deletes a logger package.

Note: The DELETE method is not required. When no logger package variables reference a logger package instance, the package instance is automatically deleted.

Syntax

package.**DELETE**( );

Required Argument

package
specifies an instance of the logger package variable.

Details

When you no longer need the logger package, delete it by using the DELETE method. If you attempt to use a logger package after you delete it, an error will be written to the log.

See Also

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

ISLEVELACTIVE Method

Returns a value that indicates whether the logger package that is associated with the logger name suppresses a message at the logger level.

Syntax

package.**ISLEVELACTIVE**(['])*level*(']);

Required Arguments

package
specifies an instance of the logger package variable.

[']*level*[']
a numeric value that specifies the level at which a logging request is applied for the specified logger package.

Requirements *level* must be a string that contains either the severity value or a one-character abbreviation for the severity value. Valid values are listed as follows.

- 2 or 'T' for TRACE
- 3 or 'D' for DEBUG
- 4 or 'I' for INFO
- 5 or 'W' for WARN
- 6 or 'E' for ERROR
- 7 or 'F' for FATAL

If a character is used for *level*, the character must be enclosed in single quotation marks. Numeric values can be quoted but do not need to be.

Example

These are examples of the ISLEVELACTIVE method.

```
mylog.islevelactive(5);

testlog.islevelactive('F');
```

See Also

"Using the Logger Package" in *SAS DS2 Programmer's Guide*

LOG Method: Logger Package

Send the specified message to the logger at the specified level.

Syntax

Form 1: *package*.**LOG**(['])*level*['], '*raw-message*');

Form 2: *package*.**LOG**(['])*level*['], [*message-format*]'*argument-1*' [..., *argument-9*]);

Required Arguments

package
specifies an instance of the logger package variable.

['])*level*['])
a numeric value that specifies the level at which a logging request is applied for the specified logger package.

Requirements *level* must be a string that contains either the severity value or a one-character abbreviation for the severity value. Valid values are listed as follows. Note that any part of the word that indicates the level is valid. For example, *i*, *in*, *inf*, or *info* is valid.

- 2 or 'T' for TRACE
- 3 or 'D' for DEBUG
- 4 or 'I' for INFO
- 5 or 'W' for WARN
- 6 or 'E' for ERROR
- 7 or 'F' for FATAL

If a character is used for *level*, the character must be enclosed in single quotation marks. Numeric values can be quoted but do not need to be.

'raw-message'
specifies the message to write at the level.

Range 1–65535 characters

Requirement The message is a string and must be enclosed in single quotation marks.

Tip The message can be any character type expression. Here is an example, `x.log(5, 'Error while processing function' ||`

`trimn(FNAME));`. However, using a character expression causes a conversion from a CHAR data type to an NCHAR data type. It is faster to use a character string.

argument
specifies a value that replaces the $s format marker in the *message-format*.

Interaction If the LOG method has more than two parameters and the level is valid, each $s format marker in the *message-format* is replaced by the content of the corresponding *argument*.

Tip Extra arguments are ignored when using formatted output.

Optional Argument

message-format
specifies a message format that is used to produce the log message. The message format contains at least one $s format marker.

Requirement The number of $s format markers must be less than or equal to the number of arguments. Otherwise, an error occurs.

Interaction If the LOG method has more than two parameters and the level is valid, each $s format marker is replaced by the content of the corresponding *argument*.

Tip To display a dollar sign ($) in your message, use $$ in the $s format marker.

Details

Unformatted Messages (Form 1)

A LOG method call with exactly two parameters, an active logger, and a valid level, sends the specified message to the associated logger in its raw format.

Formatted Messages (Form 2)

A LOG method call with more than two parameters, an active logger, and a valid level, sends a formatted message to the associated logger. Each $s format marker in the *message-format* is replaced by the content of the corresponding *argument*.

Examples

Example 1: Unformatted Messages

These are examples of unformatted messages.

```
mylog.log('T', 'The output was written to the log');

testlog.log(7, 'The output could not be written');
```

Example 2: Formatted Messages

The following example shows several combinations of $s format markers.

Note: In this example code, DS2 statements are sent to SAS using PROC DS2.

```
proc ds2;
   data _NULL_;
   dcl package logger root();
   method init();
     /* $$ is not evaluated here - one parameter */
     root.log(n'note', 'one-parm dollar pair: $$');
     /* $s is not evaluated here - one parameter */
     root.log(n'note', 'one-parm dollar-s: $s');
     /* $$ is evaluated here and "mine" is substituted for $s */
     root.log(n'note', 'dollar pair: $$; me:$s', n'mine');
     /* "mine" is substituted for $s */
     root.log(n'note', 'me:$s', n'mine');
     /* "mine" is substituted for the first $s */
     /* "thine" is substituted for the second $s */
     root.log(n'note', 'me:$s thee:$s', n'mine', n'thine');
     /* there are five arguments */
     root.log(n'note', 'one:$s two:$s three:$s four:$s five:$s', 1N, 2, 3.0, n'4', '5');
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
NOTE: one-parm dollar pair: $$
NOTE: one-parm dollar-s: $s
NOTE: dollar pair: $; me:mine
NOTE: me:mine
NOTE: me:mine thee:thine
NOTE: one:1 two:2 three:3 four:4 five:5
NOTE: Execution succeeded. No rows affected.
```

NEW Operator: Logger Package

Constructs an instance of a logger package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_ LOGGER**([*logger-name*]);

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a logger package variable using the DECLARE PACKAGE statement. After you declare a logger package variable, use the _NEW_ operator to instantiate an instance of the logger package and assign the new package instance to the logger package variable.

```
declare package logger mylog;
mylog = _new_ logger( );
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a logger package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package logger mylog( );
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

DS2 Matrix Package Methods, Operators, and Statements

Dictionary

ABS Method

Returns a matrix that contains the absolute value of each value in the input matrix.

Syntax

r=*package*.**ABS**( );

Required Arguments

r
specifies a matrix that contains the absolute value of each value in the input matrix.

package
specifies an instance of the matrix package variable.

See Also

"Matrix Operations" in *SAS DS2 Programmer's Guide*

ADD Method: Matrix Package

Adds one matrix to another.

Syntax

r=*package-1*.**ADD**(*package-2*);

Required Arguments

r
specifies the matrix that is automatically created by the ADD method.

package-1
specifies an instance of the first matrix package variable that is used in the addition operation.

package-2
specifies an instance of the second matrix package variable that is used in the addition operation.

Details

The matrix dimensions for the ADD method must be the same size in order for the matrix addition to take place. Each [i, j] element in the first matrix is added to its corresponding [i, j] element in the second matrix.

If you add matrices that have missing values, you do not receive an error.

It is also possible to perform scalar addition by using a 1x1 matrix.

Examples

Example 1: Adding Two Matrices

Here is an example of using the ADD method to add two 3x3 matrices. Each [i, j] element in the first matrix is added to its corresponding [i, j] element in the second matrix.

```
data _null_;
   dcl double a[3,3];
   dcl double b[3,3];
   dcl double c[3,3];
```

```
   method run();
      dcl package matrix m;
      dcl package matrix m2;
      dcl package matrix r;
      dcl double i j;

      a := (1,2,3,4,5,6,7,8,9);
      b := (1,5,9,2,6,10,3,7,1);

      m = _new_ matrix(a, 3, 3);
      m2 = _new_ matrix(b, 3, 3);

      r = m.add(m2);
      r.toarray(c);

      do i = 1 to 3;
         do j = 1 to 3;
             put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
2
7
12
6
11
16
10
15
10
```

Example 2: Scalar Addition of Two Matrices

Here is an example of how to perform scalar addition by using a 1x1 matrix.

```
data _null_;
   dcl double c[3,3];
   dcl double d[1,1];
   dcl double f[3,3];
   method run();
      dcl package matrix m3;
      dcl package matrix m4;
      dcl package matrix r;
      dcl double i j;

      c := (-0, 0, -1, 1, -2.2, 2.2, -3.3, 4.4, 5.5);
      d := (1);

      m3 = _new_ matrix(c, 3, 3);
      m4 = _new_ matrix(d, 1, 1);

      r = m3.add(m4);
      r.toarray(f);
```

```
      do i = 1 to 3;
         do j = 1 to 3;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

In this example, 1 was added to each entry in matrix *m3*. The scalar addition produces a 3x3 matrix that has the following values:

```
1      1     0
2      -1.2   3.2
-2.3   5.4   6.5
```

Methods:

- "SUB Method" on page 1903

ALL_AND Method

Produces a scalar result in an ALL_AND comparison between all elements in one matrix and all elements in another matrix.

Syntax

x=*package-1*.**ALL_AND**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL AND comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL AND comparison.

Details

The ALL_AND logical operation produces a result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the logical [i, j]operations must be true. Otherwise, the result is 0.

The matrix sizes must match or you can also use a scalar comparison.

Comparisons

The ANY_AND operation is similar to the ALL_AND operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_and(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_OR Method" on page 1846
- "AND Method" on page 1847
- "ANY_AND Method" on page 1848

ALL_EQ Method

Produces a scalar result in an ALL_EQ (ALL equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_EQ**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL equal-to comparison.

Details

The ALL_EQ relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the [i, j]element comparisons must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_EQ operation is similar to the ALL_EQ operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_eq(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_NE Method" on page 1845
- "ANY_EQ Method" on page 1849

ALL_GE Method

Produces a scalar result in an ALL_GE (ALL greater-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_GE**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL greater-than-or-equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL greater-than-or-equal-to comparison.

Details

The ALL_GE relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the [i, j] element comparisons must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_GE operation is similar to the ALL_GE operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_ge(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_LE Method" on page 1842
- "ALL_NE Method" on page 1845
- "ANY_GE Method" on page 1851

ALL_GT Method

Produces a scalar result in an ALL_GT (ALL greater-than) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_GT**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL greater-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL greater-than comparison.

Details

The ALL_GT relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the [i, j]element comparisons must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_GT operation is similar to the ALL_GT operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_gt(m2);
```

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_GE Method" on page 1840
- "ALL_LT Method" on page 1843
- "ANY_GT Method" on page 1852

ALL_LE Method

Produces a scalar result in an ALL_LE (ALL less-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_LE**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL less-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL less-than comparison.

Details

The ALL_LE relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the [i, j] element comparisons must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_LE operation is similar to the ALL_LE operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_le(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_GE Method" on page 1840
- "ALL_LT Method" on page 1843
- "ANY_LE Method" on page 1853

ALL_LT Method

Produces a scalar result in an ALL_LT (ALL less-than) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_LT**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL less-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL less-than comparison.

Details

The ALL_LT relational operation produces a scalar result that indicates whether an $[i, j]^{th}$ element of the first matrix satisfies the comparison with the $[i, j]^{th}$ element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the [i, j] element comparisons must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_LT operation is similar to the ALL_LT operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_lt(m2);
```

ALL_NE Method

Produces a scalar result in an ALL_NE (ALL not-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_NE**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL not-equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL not-equal-to comparison.

Details

The ALL_NE relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the [i, j] element comparisons must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_NE operation is similar to the ALL_NE operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_ne(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_EQ Method" on page 1838
- "ANY_NE Method" on page 1856

ALL_OR Method

Produces a scalar result in an ALL_OR comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ALL_OR**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ALL OR comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ALL OR comparison.

Details

The ALL_OR logical operation produces a result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. In order for the result to be 1, all of the logical [i, j] operations must be true. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ANY_OR operation is similar to the ALL_OR operation except that if any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

Example

```
x=m1.all_or(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_AND Method" on page 1837
- "ANY_OR Method" on page 1857
- "OR Method" on page 1898

AND Method

Compares two matrices based on the AND logical operation, and returns the resulting matrix.

Syntax

r=*package-1*.**AND**(*package-2*);

Required Arguments

r
specifies a matrix that contains the results of an AND comparison between the values of two matrices.

package-1
specifies an instance of the first matrix package variable that is used in the AND comparison.

package-2
specifies an instance of the second matrix package variable that is used in the AND comparison.

Details

The AND logical operator behaves similarly to the binary relational operations (LT, LE, GE, GT, NE, and EQ). In each case, the AND logical operation is applied to the [i, j]th elements of two matrices and placed in the result matrix *r*.

The matrix sizes must match or you can use a scalar comparison.

Example

```
r=m1.and(m2);
```

- "OR Method" on page 1898

ANY_AND Method

Produces a scalar result in an ANY_AND comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_AND**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY AND comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY AND comparison.

Details

The ANY_AND logical operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the logical [i, j] operations is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_AND operation is similar to the ANY_AND operation except that all of the logical [i, j] operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_and(m2);
```

ANY_EQ Method

Produces a scalar result in an ANY_EQ (ANY equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_EQ**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY equal-to comparison.

Details

The ANY_EQ relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_EQ operation is similar to the ANY_EQ operation except that all of the logical [i, j] operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_eq(m2);
```

ANY_GE Method

Produces a scalar result in an ANY_GE (ANY greater-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_GE**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY greater-than-or-equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY greater-than-or-equal-to comparison.

Details

The ANY_GE relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_GE operation is similar to the ANY_GE operation except that all of the logical [i, j] operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_ge(m2);
```

ANY_GT Method

Produces a scalar result in an ANY_GT (ANY greater-than) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_GT**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY greater-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY greater-than comparison.

Details

The ANY_GT relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_GT operation is similar to the ANY_GT operation except that all of the logical [i, j] operations has to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_gt(m2);
```

ANY_LE Method

Produces a scalar result in an ANY_LE (any less-than-or-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_LE**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY less-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY less-than comparison.

Details

The ANY_LE relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_LE operation is similar to the ANY_LE operation except that all of the logical [i, j] operations has to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_le(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_LE Method" on page 1842
- "ANY_GE Method" on page 1851
- "ANY_LT Method" on page 1854

ANY_LT Method

Produces a scalar result in an ANY_LT (ANY less-than) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_LT**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY less-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY less-than comparison.

Details

The ANY_LT relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_LT operation is similar to the ANY_LT operation except that all of the logical [i, j] operations has to be true for the result to be 1. Otherwise, the result is 0.

Example

The following example produces a result of 1 because the [1, 2] element of matrix *m* (= =2) is less than the [1, 2] element of matrix *m2* (= =5). All of the other elements do not satisfy the comparison. If the [1, 2] element of matrix *m* was changed to 6, for example, the result would be 0.

```
data _null_;
   dcl double a[3,3];
   dcl double b[3,3];
   dcl double r;

   method run();
      dcl package matrix m;
      dcl package matrix m2;

      a := (1,2,10,4,7,11,15,9,12);
      b := (1,5,9,2,6,10,3,7,11);

      m = _new_ matrix(a, 3, 3);
      m2 = _new_ matrix(b, 3, 3);
```

```
      r = m.any_lt(m2);
      put r=;
   end;
enddata;
run;
```

ANY_NE Method

Produces a scalar result in an ANY_NE (ANY not-equal-to) comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_NE**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY not-equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY not-equal-to comparison.

Details

The ANY_NE relational operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element

of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_NE operation is similar to the ANY_NE operation except that all of the logical [i, j] operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_ne(m2);
```

ANY_OR Method

Produces a scalar result in an ANY_OR comparison between elements in one matrix and elements in another matrix.

Syntax

x=*package-1*.**ANY_OR**(*package-2*);

Required Arguments

x
specifies the scalar result.

package-1
specifies an instance of the first matrix package variable that is used in the ANY OR comparison.

package-2
specifies an instance of the second matrix package variable that is used in the ANY OR comparison.

Details

The ANY_OR logical operation produces a scalar result that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The scalar result is 0 or 1. If any of the [i, j] element comparisons is true, then the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Comparisons

The ALL_OR operation is similar to the ANY_OR operation except that all of the logical [i, j] operations have to be true for the result to be 1. Otherwise, the result is 0.

Example

```
x=m1.any_or(m2);
```

COLS Method

Returns the number of columns in the specified matrix.

Syntax

variable-name=*package*.**COLS**( );

Required Arguments

variable-name
specifies the name of a variable that contains the number of columns after the method is complete.

package
specifies an instance of the matrix package variable.

Example

See the example in the ROWS method on page 1902.

See Also

- "Using the MATRIX Package" in *SAS DS2 Programmer's Guide*

Methods:

- "ROWS Method" on page 1901

COPY Method

Copies one matrix to another.

Syntax

r=*package*.**COPY**( );

Required Arguments

r
specifies the matrix that is automatically created by the COPY method.

package
specifies an instance of the matrix package variable.

Details

The COPY method copies a matrix into a new matrix.

Example

This example creates a new copy of a 3x4 matrix.

```
data _null_;
   dcl double a[3,4];
   dcl double b[3,4];

   method run();
      dcl package matrix m;
      dcl package matrix r;
      dcl double i j;

      a := (1,2,3,4,5,6,7,8,9,10,11,12);

      m = _new_ matrix(a, 3, 4);
      r = m.copy();
      r.toarray(b);

      do i = 1 to 3;
         do j = 1 to 4;
            put b[i,j];
         end;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
1
2
3
4
5
6
7
8
9

"Using the MATRIX Package" in *SAS DS2 Programmer's Guide*

DECLARE PACKAGE Statement: Matrix Package

Creates an instance of a MATRIX package.

Category: Local

Syntax

DECLARE PACKAGE MATRIX *variable* ([*row-dimension*, *column-dimension*]);

Required Argument

variable
specifies a name that can reference an instance of the matrix package.

Optional Arguments

row-dimension
specifies the row dimension for the matrix.

column-dimension
specifies the column dimension for the matrix.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

The matrix package provides a DS2-level implementation of SAS/IML functionality. The matrix package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

A matrix package is created by declaring and instantiating the package using the DECLARE PACKAGE statement.

This example creates an empty 2x2 matrix, and stores the instance in the variable *m*.

```
declare package matrix m(2, 2);
```

A matrix must be initialized before it can be used, and initialization is done in the code stream, not in the declarations. You can use the following actions to load data into a matrix instance.

- _NEW_ operator to load an array
- IN method to load an array
- SET statement to load external data

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

See Also

- "Declaring and Instantiating a MATRIX Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Methods:

- "IN Method" on page 1881

Operators:

- "_NEW_ Operator: Matrix Package" on page 1891

Statements:

- "SET Statement" on page 1430

DELETE Method: Matrix Package

Deletes a matrix package.

Note: The DELETE method is not required. When no matrix package variables reference a matrix package instance, the package instance is automatically deleted.

Syntax

package.**DELETE**( );

Required Argument

package
specifies an instance of the matrix package variable.

Details

When you no longer need the matrix package, delete it by using the DELETE method. If you attempt to use a matrix package after you delete it, an error will be written to the log.

See Also

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

DET Method

Computes the determinant of a square matrix.

Syntax

d=*package*.**DET**( );

Required Arguments

d
specifies the matrix that is automatically created by the DET method.

package
specifies an instance of the matrix package variable.

Details

The input matrix for a determinant must be square. Otherwise, you receive a run-time error. The output from the DET method is a real or complex number that is called the determinant.

Example

The following example computes a determinant for a 3x3 matrix.

```
data _null_;
   dcl double a[3,3];

   method run();
      dcl package matrix m;
```

```
      dcl double d;

      a := (1,3,2,5,4,6,9,8,9);
      m = _new_ matrix(a, 3, 3);
      d = m.det();
      put d=;
   end;
enddata;
run;
```

The following line is written to the SAS log.

```
d=23
```

"Matrix Operations" in *SAS DS2 Programmer's Guide*

EDIV Method

Performs an elementwise scalar division.

Syntax

x=*package-1*.**EDIV**(*package-2*);

Required Arguments

x
specifies the matrix that is automatically created by the EDIV method.

package-1
specifies an instance of the first matrix package variable that is used in the elementwise division operation.

package-2
specifies an instance of the second matrix package variable that is used in the elementwise division operation.

Details

The EDIV method enables you to apply the elementwise scalar division of one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as

- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EDIV method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

```
x=m1.ediv(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "EMULT Method" on page 1871

EMAX Method

Performs an elementwise comparison of two matrices and returns the largest elements.

Syntax

x=*package-1*.**EMAX**(*package-2*);

Required Arguments

x
specifies the matrix that is automatically created by the EMAX method.

package-1
specifies an instance of the first matrix package variable that is used in the elementwise maximum operation.

package-2
specifies an instance of the second matrix package variable that is used in the elementwise maximum operation.

Details

The EMAX method enables you to apply an elementwise maximum value comparison to one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMAX method produces a result matrix from the element-by-element operations on the two argument matrices.

Examples

Example 1: Comparing Maximum Values Using a 1x1 Matrix

The following example creates a matrix that contains the maximum value from two 2x2 matrices.

```
data _null_;
   dcl double a[2,2];
   dcl double b[2,2];
   dcl double f[2,2];

   method run();
      dcl package matrix m;
      dcl package matrix m1;
        dcl package matrix r;
        dcl double i j;

      a := (2, 2, 3, 4);
        b := (4, 5, 1, 0);

      m = _new_ matrix(a, 2, 2);
        m1 = _new_ matrix(b, 2, 2);

      r = m.emax(m1);
        r.toarray(f);

         do i = 1 to 2;
         do j = 1 to 2;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
4  5
3  4
```

Example 2: Vector Operation on a Matrix

In this example, the maximum operator is applied to all the rows of matrix **m** by using the matrix **m1** as a row.

```
data _null_;
   method init();
      dcl package matrix m;
      dcl package matrix m1;
      dcl package matrix r;
      dcl double i j;
      dcl double a[4];
      dcl double b[2];
      dcl double f[2,2];

      a := (2, 2, 3, 4);
      b := (1, 5);
      m = _new_ matrix(a, 2, 2);
      m1 = _new_ matrix(b, 1, 2);
      r = m.emax(m1);
      r.toarray(f);
      do i = 1 to 2;
         do j = 1 to 2;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
2
5
3
5
```

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "EMIN Method" on page 1867

EMIN Method

Performs an elementwise comparison of two matrices and returns the smallest elements.

Syntax

x=*package-1*.**EMIN**(*package-2*);

Required Arguments

x
specifies the matrix that is automatically created by the EMIN method.

package-1
specifies an instance of the first matrix package variable that is used in the elementwise minimum operation.

package-2
specifies an instance of the second matrix package variable that is used in the elementwise minimum operation.

Details

The EMIN method enables you to apply an elementwise minimum value comparison of one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMIN method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example creates a matrix that contains the maximum value from two 2x2 matrices.

```
data _null_;
   dcl double a[2,2];
   dcl double b[2,2];
   dcl double f[2,2];

   method run();
      dcl package matrix m;
      dcl package matrix m1;
         dcl package matrix r;
         dcl double i j;

      a := (2, 2, 3, 4);
```

```
        b := (4, 5, 1, 0);

      m = _new_ matrix(a, 2, 2);
        m1 = _new_ matrix(b, 2, 2);

      r = m.emin(m1);
         r.toarray(f);

        do i = 1 to 2;
         do j = 1 to 2;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
2  2
1  0
```

- "EMAX Method" on page 1865

EMOD Method

Returns the remainder of the division of elements of the first matrix by elements of the second matrix in an elementwise scalar operation.

Syntax

x=*package-1*.**EMOD**(*package-2*);

Required Arguments

x
specifies the matrix that is automatically created by the EMOD method.

package-1
specifies an instance of the first matrix package variable that is used in the elementwise MOD comparison.

package-2
specifies an instance of the second matrix package variable that is used in the elementwise MOD comparison.

Details

The EMOD elementwise operation enables you to find the remainder of a division operation on one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMOD method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example divides the elements in matrix, **m**, by the elements in matrix, **m2**. The EMOD method is used to return the matrix of remainders, **f**.

```
data _null_;
   dcl double a[2,2];
   dcl double b[2,2];
   dcl double f[2,2];

   method run();
      dcl package matrix m;
      dcl package matrix m1;
        dcl package matrix r;
        dcl double i j;

      a := (125, 17, 39, 40);
        b := (40, 5, 12, 8);

      m = _new_ matrix(a, 2, 2);
        m1 = _new_ matrix(b, 2, 2);

      r = m.emod(m1);
        r.toarray(f);

        do i = 1 to 2;
         do j = 1 to 2;
            put f[i,j];
         end;
      end;
   end;
```

```
enddata;
run;
```

The resulting matrix has the following values.

```
5  2
3  0
```

"Matrix Operations" in *SAS DS2 Programmer's Guide*

EMULT Method

Performs an elementwise scalar multiplication.

Syntax

r=*package-1*.**EMULT**(*package-2*);

Required Arguments

r
specifies the matrix that is automatically created by the EMULT method.

package-1
specifies an instance of the first matrix package variable that is used in the elementwise multiplication operation.

package-2
specifies an instance of the second matrix package variable that is used in the elementwise multiplication operation.

Details

The EMULT method enables you to apply the elementwise scalar multiplication on one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EMULT method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example shows how to perform an elementwise scalar multiplication. Each element of matrix *c* is multiplied by 2.

```
data _null_;
   dcl double c[3,3];
   dcl double d[1,1];
   dcl double f[3,3];

   method run();
      dcl package matrix m3;
      dcl package matrix m4;
      dcl package matrix r;
        dcl double i j;

      c := (-0, 0, -1, 1, -2.2, 2.2, -3.3, 4.4, 5.5);
      d := (2);

      m3 = _new_ matrix(c, 3, 3);
      m4 = _new_ matrix(d, 1, 1);

      r = m3.emult(m4);
      r.toarray(f);

      do i = 1 to 3;
         do j = 1 to 3;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
0     0     -2
2    -4.4   4.4
-6.6  8.8   11
```

EPOW Method

Raises a number to a specified power in an elementwise operation.

Syntax

x=*package-1*.**EPOW**(*package-2*);

Required Arguments

x
specifies the matrix that is automatically created by the EPOW method.

package-1
specifies an instance of the first matrix package variable that is used in the elementwise operation.

package-2
specifies an instance of the second matrix package variable that is used in the elementwise operation.

Details

The EPOW elementwise operation enables you to raise a value exponentially in one matrix using another matrix. The second matrix can be any of the following:

- a matrix with the same dimensions as
- a vector whose row dimension matches the row dimension of the first matrix
- is a vector whose column dimension matches the column dimension of the first matrix
- a 1x1 matrix effectively allowing a scalar operation on each [i,j] element

The EPOW method produces a result matrix from the element-by-element operations on the two argument matrices.

Example

The following example raises each element of matrix *c* to a power of 2.

```
data _null_;
   dcl double c[3,3];
   dcl double d[1,1];
   dcl double f[3,3];
```

```
   method run();
      dcl package matrix m3;
      dcl package matrix m4;
      dcl package matrix r;
        dcl double i j;

      c := (0, 15, 1.7, 13, -2.2, 10, -3.3, 7, 2);
      d := (2);

      m3 = _new_ matrix(c, 3, 3);
      m4 = _new_ matrix(d, 1, 1);

      r = m3.epow(m4);
      r.toarray(f);

      do i = 1 to 3;
         do j = 1 to 3;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
0     225    2.89
169   4.84   100
10.89 49   4
```

"Matrix Operations" in *SAS DS2 Programmer's Guide*

EQ Method

Produces a scalar result in an equal-to comparison between elements in one matrix and elements in another matrix.

Syntax

r=*package-1*.**EQ**(*package-2*);

Required Arguments

r
specifies a matrix that contains the results of an equal-to comparison between the values of two matrices.

package-1
specifies an instance of the first matrix package variable that is used in the equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the equal-to comparison.

Details

The EQ relational operation produces a matrix that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The result is 0 or 1. If the [i, j] elements are equal, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example

The following example compares the elements in two matrices for equality. Note that missing values are compared.

```
data _null_;
   dcl double a[2,2];
   dcl double b[2,2];
   dcl double f[2,2];

   method run();
      dcl package matrix m;
      dcl package matrix m1;
        dcl package matrix r;
        dcl double i j;

      a := (2, 2, 3, .);
        b := (4, 5, 1, .);

      m = _new_ matrix(a, 2, 2);
        m1 = _new_ matrix(b, 2, 2);

      r = m.eq(m1);
        r.toarray(f);

        do i = 1 to 2;
         do j = 1 to 2;
            put f[i,j];
         end;
```

```
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
0   0
0   1
```

EXP Method

Returns a matrix that contains an exponential value for each value in the input matrix.

Syntax

r=*package*.**EXP**( );

Required Arguments

r
specifies the matrix that is automatically created by the EXP method.

package
specifies an instance of matrix package variable.

Details

The EXP method creates a matrix that contains each element of the input matrix raised to the e^{th} power.

Example

The following example raises each element of a matrix to the e^{th} power.

```
data _null_;
   dcl double a[3, 3];
   dcl double c[3, 3];

   method run();
      dcl package matrix m;
      dcl package matrix r;
        dcl double i j;

      a := (1, 2, 3, 1, 2, 3, 1, 2, 3);

      m=_new_ matrix(a, 3, 3);
      r=m.exp();
      r.toarray(c);

      do i=1 to 3;
         do j=1 to 3;
            put c[i, j];
         end;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
2.71828182845904
7.38905609893065
20.0855369231876
2.71828182845904

FLOOR Method

Returns a matrix that contains the integer part of each value in the input matrix.

Syntax

r=*matrix-package*.**FLOOR**( );

Required Arguments

r
specifies a matrix that contains the integer part of each value in the input matrix.

matrix-package
specifies an instance of matrix package variable.

Example

The following example creates a matrix that contains the integer part of input matrix, **m**.

```
data _null_;
   dcl double a[2, 2];
   dcl double c[2, 2];

   method run();
      dcl package matrix m;
      dcl package matrix r;
      dcl double i j;

      a := (1323.43, -.72, 3.38, 45);

      m=_new_ matrix(a, 2, 2);
      r=m.floor();
      r.toarray(c);

      do i=1 to 2;
         do j=1 to 2;
            put c[i, j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
1323   0
3      45
```

"Matrix Operations" in *SAS DS2 Programmer's Guide*

GE Method

Produces a scalar result in a greater-than-or-equal-to comparison between elements in one matrix and elements in another matrix.

Syntax

r=*package-1*.**GE**(*package-2*);

Required Arguments

r
specifies a matrix that contains the results of a greater-than-or-equal-to comparison between the values of two matrices.

package-1
specifies an instance of the first matrix package variable that is used in the greater-than-or-equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the greater-than-or-equal-to comparison.

Details

The GE relational operation produces a matrix that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The result is 0 or 1. If the [i, j] element greater-than-or-equal-to comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example

```
r=m1.ge(m2);
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

GT Method

Produces a scalar result in a greater-than comparison between elements in one matrix and elements in another matrix.

Syntax

r=*package-1*.**GT**(*package-2*);

Required Arguments

r
specifies a matrix that contains the results of a greater-than comparison between the values in two matrices.

package-1
specifies an instance of the first matrix package variable that is used in the greater-than comparison.

package-2
specifies an instance of the first matrix package variable that is used in the greater-than comparison.

Details

The GT relational operation produces a matrix that indicates whether an $[i, j]^{th}$ element of the first matrix satisfies the comparison with the $[i, j]^{th}$ element of the second matrix. The result is 0 or 1. If the [i, j] element greater-than comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example

```
r=m1.gt(m2);
```

- "LT Method" on page 1889

IN Method

Loads an array into a matrix.

Alias: LOAD

Syntax

package.**IN**(*array-name*);

Required Arguments

package
specifies an instance of the matrix package variable.

array-name
specifies an array that is used in loading the matrix.

Restriction: The array dimensions must match the matrix dimensions. Otherwise, an error occurs.

Tip: You can use variable arrays.

See: "DS2 Arrays" in *SAS DS2 Programmer's Guide*

Details

The IN method loads an array into a matrix. This process might be useful if an array **a** can change as the program executes and you want to repeatedly reset the values of matrix **m**. Here is an example:

```
dcl double a[3, 3];
dcl package matrix m;

m=_new_ matrix(3, 3);
m.in(a);
```

You can use variable arrays to load data into a matrix. Here is an example:

```
vararray double va[3,3];
  dcl package matrix m;

  m.in(va);
```

You can also use variable arrays to input and output data using the SET and OUT statements.

Examples

Example 1: Loading and Writing Data

This example reads data from a data set in matrix form, finds the matrix inverse, and writes the result matrix to an output table. The example uses the IN and OUT methods. The IN method loads data from a variable array into a matrix. The OUT method writes the data in the matrix to a variable array. The SET and OUPUT statements are used in the program to read data from an array and write the results to an output array.

The IN and OUT methods are overloaded to accept an integer argument that tells which row of the matrix to load. For the IN method, the variable array row data is read into the matrix. For the OUT method, the matrix row data is written to the variable array.

```
/* DATA step to create an array of data */
data x;
   array a[4];

   /* Create a 4x4 matrix. */
   a1 = 1; a2 = 5; a3 = 2; a4 = 3;
   output;

   a1 = 3; a2 = 3; a3 = 1; a4 = 7;
   output;

   a1 = 2; a2 = 3; a3 = 8; a4 = 9;
   output;

   a1 = 3; a2 = 6; a3 = 7; a4 = 4;
   output;
run;

proc ds2;
data inv/overwrite=yes;

   /* global declarations */
   vararray double v[4];
   vararray double a[4];
   keep v1 v2 v3;

   dcl package matrix m;
   dcl package matrix r;
```

```
   dcl package matrix inv;
   dcl double c[4, 4];
   dcl double i j;

   /* Create an empty matrix to hold the input values. */
   method init();
      m=_new_ matrix(4, 4);
      i=1;
   end;

   /* Read and initialize each row of the matrix from VARARRAY a. */
   method run();
      set x;
      m.in(a, i);
      i + 1;
   end;

   method term();
      /* Find the inverse of the matrix. */
      inv=m.inverse();

      /* Check whether it gives an identity matrix. */
      r=m.mult(inv);
      /* Write each row of inverse to the output table */
      /* using VARARRAY v.                              */
      do i=1 to 4;
         inv.out(v, i);
         output;
      end;

      /* Print the result to see if it's the identity. */
      r.toarray(c);
      do i=1 to 4;
         do j=1 to 4;
            put c[i, j];
         end;
      end;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log.

```
1
-2.7755575615628E-17
-1.1102230246251E-16
0
1.1102230246251E-16
1
0
0
1.1102230246251E-16
5.5511151231257E-17
1
0
1.6653345369377E-16
1.6653345369377E-16
-1.6653345369377E-16
1
```

These are the key calls for the program:

```
/*  Input  */
method run();
   set x;
   m.in(a, i);
   i + 1;
end;

/* Output */
   do i=1 to 4;
      inv.out(v, i);
      output;
   end;
```

Example 2: Using the IN and OUT Methods

For another example of using the IN and OUT methods, see "Example 2: Multiply Two Matrices That Are Read from External Data" on page 1895.

See Also

- "Matrix Data Input" in *SAS DS2 Programmer's Guide*

Methods:

- "OUT Method" on page 1899

Statements:

- "OUTPUT Statement" on page 1400
- "SET Statement" on page 1430

INVERSE Method

Computes the inverse of a matrix.

Syntax

im=*matrix-package*.**INVERSE**( );

Required Arguments

im
specifies the matrix that is automatically created by the INVERSE method.

matrix-package
specifies an instance of matrix package variable.

Details

It is possible to perform basic matrix operations on a single matrix. The INVERSE matrix operation computes the inverse of a matrix. If the matrix is not square or is singular (not invertible), you receive a run-time error.

Example

The following example computes the inverse of a 3x3 matrix, and checks, using matrix multiplication, whether the resulting inverse produces the identity matrix.

```
data _null_;
   dcl double a[3,3];
   dcl double b[3,3];

   method run();
      dcl package matrix m im r;
      dcl double i j;

      a := (1, 2, -1, 2, 1, 0, -1, 1, 2);
      m = _new_ matrix(a, 3, 3);

      im = m.inverse();
      r = m.mult(im);
      r.toarray(b);

      do i = 1 to 3;
         do j = 1 to 3;
```

```
            put b[i,j];
         end;
      end;
   end;
enddata;
run;
```

Some values of the resulting matrix are not exactly zero. The values might be very small numbers, such as 1.1102230246251E-16. These small numbers are the exact results that the SAS/IML subsystem provides.

```
1                    5.5511151231257E-17    0
0                    1                    0
1.1102230246251E-16    -1.1102230246251E-16    1
```

"Matrix Operations" in *SAS DS2 Programmer's Guide*

LE Method

Produces a scalar result in a less-than-or-equal-to comparison between elements in one matrix and elements in another matrix.

Syntax

r=*package-1*.**LE**(*package-2*);

Required Arguments

r
specifies a matrix that contains the results of a less-than-or-equal-to comparison between the values of two matrices.

package-1
specifies an instance of the first matrix package variable that is used in the less-than-or-equal-to comparison.

package-2
specifies an instance of the second matrix package variable that is used in the less-than-or-equal-to comparison.

Details

The LE relational operation produces a matrix that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The result is 0 or 1. If the [i, j] element less-than-or-equal-to comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Examples

Example 1: Comparing Two Matrices Using the LE Method

The following example uses the LE method. The [i, j]th element of matrix **m** is compared with the [i, j] element of matrix **m2**, using 0 or 1 for the result entries.

```
data _null_;
   dcl double a[3,3];
   dcl double b[3,3];
   dcl double c[3,3];

   method run();
      dcl package matrix m;
      dcl package matrix m2;
      dcl package matrix r;
      dcl double i j;

      a := (1,2,3,4,5,6,7,8,9);
      b := (1,5,9,2,6,10,3,7,11);

      m = _new_ matrix(a, 3, 3);
      m2 = _new_ matrix(b, 3, 3);

      r = m.le(m2);
      r.toarray(c);

      do i = 1 to 3;
         do j = 1 to 3;
            put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
1   1   1
0   1   1
0   0   1
```

Example 2: Using a Scalar Matrix

The following example uses a scalar matrix with the LE method.

```
data _null_;
   dcl double a[3,3];
   dcl double b[1,1];
   dcl double c[3,3];

   method run();
      dcl package matrix m;
      dcl package matrix m2;
      dcl package matrix r;
      dcl double i j;

      a := (1,3,3,4,5,6,7,8,9);
      b := (4);

      m = _new_ matrix(a, 3, 3);
      m2 = _new_ matrix(b, 1, 1);

      r = m.le(m2);
      r.toarray(c);

      do i = 1 to 3;
         do j = 1 to 3;
             put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
1   1   1
1   0   0
0   0   0
```

Methods:

- "GE Method" on page 1879
- "LT Method" on page 1889

LOG Method: Matrix Package

Returns a matrix that contains the natural logarithm for each value in the input matrix.

Syntax

r=*package*.**LOG**( );

Required Arguments

r
specifies a matrix that is automatically created by the LOG method.

package
specifies an instance of matrix package variable.

See Also

"Matrix Operations" in *SAS DS2 Programmer's Guide*

LT Method

Produces a scalar result in a less-than comparison between elements in one matrix and elements in another matrix.

Syntax

r=*package-1*.**LT**(*package-2*);

Required Arguments

r
specifies a matrix that contains the results of a less-than comparison between the values in two matrices.

package-1
specifies an instance of the first matrix package variable that is used in the less-than comparison.

package-2
specifies an instance of the second matrix package variable that is used in the less-than comparison.

Details

The LT relational operation produces a matrix that indicates whether an $[i, j]^{th}$ element of the first matrix satisfies the comparison with the $[i, j]^{th}$ element of the

second matrix. The result is 0 or 1. If the [i, j] element less-than comparison is true, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Examples

Example 1: Comparing Two Matrices Using the LT Method

The following example uses the LT method. The [i, j]th element of matrix **m** is compared with the [i, j] element of matrix **m2**, using 0 or 1 for the result entries.

```
data _null_;
   dcl double a[3,3];
   dcl double b[3,3];
   dcl double c[3,3];

   method run();
      dcl package matrix m;
      dcl package matrix m2;
      dcl package matrix r;
      dcl double i j;

      a := (1,2,3,4,5,6,7,8,9);
      b := (1,5,9,2,6,10,3,7,11);

      m = _new_ matrix(a, 3, 3);
      m2 = _new_ matrix(b, 3, 3);

      r = m.lt(m2);
      r.toarray(c);

      do i = 1 to 3;
         do j = 1 to 3;
            put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
0   1   1
0   1   1
0   0   1
```

Example 2: Using a Scalar Matrix

The following example uses a scalar matrix with the LT method.

```
data _null_;
   dcl double a[3,3];
   dcl double b[1,1];
   dcl double c[3,3];
```

```
   method run();
      dcl package matrix m;
      dcl package matrix m2;
      dcl package matrix r;
      dcl double i j;

      a := (1,3,3,4,5,6,7,8,9);
      b := (4);

      m = _new_ matrix(a, 3, 3);
      m2 = _new_ matrix(b, 1, 1);

      r = m.lt(m2);
      r.toarray(c);

      do i = 1 to 3;
         do j = 1 to 3;
             put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
1   1   1
0   0   0
0   0   0
```

NEW Operator: Matrix Package

Constructs an instance of a matrix package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable=**_NEW_**

MATRIX([*array-name*,] *rows*, *columns*)

Required Arguments

package-variable
specifies a name that can reference an instance of the matrix package.

rows
specifies the number of rows in the matrix.

columns
specifies the number of columns in the matrix.

Optional Argument

array-name
specifies the name of an array to load into the matrix package.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a matrix package variable using the DECLARE PACKAGE statement. After you declare a matrix package variable, use the _NEW_ operator to instantiate an instance of the matrix package and assign the new package instance to the matrix package variable.

A matrix must be initialized before it can be used, and initialization is done in the code stream, not in the declarations. To initialize a matrix, you can use the _NEW_ operator or the DECLARE statement.

A matrix can be initialized with values from a DS2 array. Here is an example:

```
method init();
   dcl double a[3, 3];
   dcl package matrix m;

   a :=(1, 2, -1, 2, 1, 0, -1, 1, 2);
   m=_new_ matrix(a, 3, 3);
end;
```

In this example, a 3x3 array is initialized with values that you specify, and is used to set up the matrix *m*. The values are read in row-major order, and the matrix that is produced has the following values:

```
 1     2    -1
 2     1     0
-1     1     2
```

You can also initialize a matrix by using a variable array, as the following example shows:

```
vararray double a [3, 3];
dcl package matrix m;

method init();
   a := (1, 2, -1, 2, 1, 0, -1, 1, 2);
   m=_new_ matrix(a, 3, 3);
end;
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

Statements:

- "DECLARE PACKAGE Statement: Matrix Package" on page 1861

MULT Method

Multiplies one matrix by another matrix.

Syntax

r=*matrix-package-1*.**MULT**(*matrix-package-2*);

Required Arguments

r
specifies the matrix that is automatically created by the MULT method.

matrix-package-1
specifies the name of the first matrix package that is used in the multiplication operation.

matrix-package-2
specifies the name of the second matrix package that is used in the multiplication operation.

Details

The MULT method automatically creates a matrix that contains the result of matrix multiplication. The result matrix has the same number of rows as the first matrix and the same number of columns as the second matrix.

The following considerations apply when performing matrix multiplication.

- Array dimensions for the matrices that are used in multiplication operations must be compatible. Multiplication requires that the number of columns in the first matrix be equal to the number of rows in the second matrix. Otherwise, a run-time error is generated.
- If you multiply matrices that have missing values, you receive a run-time error.

Examples

Example 1: Simple Matrix Multiplication

The following example uses the MULT method to perform a simple matrix multiplication. A 3x4 matrix, **m**, is multiplied by a 4x3 matrix, **m2**, to obtain a 3x3 result. The result is stored in matrix, **r**. The values in matrix **r** can be placed into a 3x3 array, **c**, and written to the SAS log.

```
data _null_;
   dcl double a[3,4];
   dcl double b[4,3];
   dcl double c[3,3];

   method run();
      dcl package matrix m;
      dcl package matrix m2;
      dcl package matrix r;
      dcl double i j;

      a := (1,2,3,4,5,6,7,8,9,10,11,12);
      b := (1,5,9,2,6,10,3,7,11,4,8,12);

      m = _new_ matrix(a, 3, 4);
      m2 = _new_ matrix(b, 4, 3);

      r = m.mult(m2);
      r.toarray(c);

      do i = 1 to 3;
         do j = 1 to 3;
            put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
30
70
110
70
174
278
110
278
446
```

Example 2: Multiply Two Matrices That Are Read from External Data

This example multiplies two matrices that are read from external data. The IN method reads the matrices and the OUT method writes the output. The IN method is an alias for the LOAD method.For more information, see the "IN Method" on page 1881 and the "OUT Method" on page 1899.

```
proc ds2;
 data x(keep =(a1 a2 a3)) y(keep=(b1 b2 b3 b4))/overwrite=yes;
   vararray double a[3];
   vararray double b[4];

   method init();
      dcl double i j;

      /* Create output for matrix a */
      do i = 1 to 4;
        do j = 1 to 3;
          a[j] = 2 * j + i;
        end;
      output x;
      end;

      /* Create output for matrix b */
      do i = 1 to 3;
        do j = 1 to 4;
          b[j] = 3 * j - 2 * i;
        end;
      output y;
      end;
   end;
enddata;
run;
quit;

proc ds2;
data z(keep =(v1 v2 v3 v4))/overwrite=yes;
   drop i;
   vararray double v[4];
   vararray double a[3];
   vararray double b[4];
   dcl package matrix ma mb;
   dcl package matrix r;

   method init();
      dcl double i;
```

```
      ma = _new_ matrix(4,3);
      mb = _new_ matrix(3,4);

      /* Read matrix a (row-by-row) */

      do i = 1 to 4;
         set x;
         ma.in(a, i);
      end;

      /* Read matrix b (row-by-row) */
      do i = 1 to 3;
         set y;
         mb.in(b, i);
      end;
   end;

   method term();
      dcl double i;
      /* Multiply matrices */
      r = ma.mult(mb);

      /* Output result */
      do i = 1 to 4;
         r.out(v, i);
         output;
      end;
   end;
enddata;
run;
quit;
```

NE Method

Produces a scalar result in a not-equal-to comparison between elements in one matrix and elements in another matrix.

Syntax

r=*matrix-package-1*.**NE**(*matrix-package-2*);

Required Arguments

r
specifies a matrix that contains the results of a not-equal-to comparison between the values in two matrices.

matrix-package-1
specifies the name of the first matrix package that is used in the not-equal-to comparison.

matrix-package-2
specifies the name of the second matrix package that is used in the not-equal-to comparison.

Details

The NE relational operation produces a matrix that indicates whether an [i, j]th element of the first matrix satisfies the comparison with the [i, j]th element of the second matrix. The result is 0 or 1. If the [i, j] elements are not equal, the result is 1. Otherwise, the result is 0.

The matrix sizes must match or you can use a scalar comparison.

Example

The following example compares the elements in two matrices for inequality. Note that missing values are compared.

```
data _null_;
   dcl double a[2,2];
   dcl double b[2,2];
   dcl double f[2,2];

   method run();
      dcl package matrix m;
      dcl package matrix m1;
        dcl package matrix r;
        dcl double i j;

      a := (2, 2, 3, .);
        b := (4, 5, 1, .);

      m = _new_ matrix(a, 2, 2);
        m1 = _new_ matrix(b, 2, 2);

      r = m.ne(m1);
```

```
        r.toarray(f);

        do i = 1 to 2;
         do j = 1 to 2;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting matrix has the following values.

```
1   1
1   0
```

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "EQ Method" on page 1874
- "GE Method" on page 1879
- "LE Method" on page 1886

OR Method

Compares two matrices based on the OR logical operation, and returns the resulting matrix.

Syntax

r=*matrix-package-1*.**OR**(*matrix-package-2*);

Required Arguments

r
specifies a matrix that contains the results of an OR comparison between the values of two matrices.

matrix-package-1
specifies the name of the first matrix package that is used in the OR comparison.

matrix-package-2
specifies the name of the second matrix package that is used in the OR comparison.

Details

The OR logical operator behaves similarly to the binary relational operations (LT, LE, GE, GT, NE, and EQ). In each case, the OR logical operation is applied to the [i, j]th elements of two matrices and placed in the result matrix *r*.

Example

```
r=m1.or(m2);
```

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

- "ALL_OR Method" on page 1846
- "AND Method" on page 1847
- "ANY_OR Method" on page 1857

OUT Method

Writes matrix row data to a variable array.

Syntax

matrix-package.**OUT**(*array-name*);

Required Arguments

matrix-package
specifies a matrix package to be used with the OUT method.

array-name
specifies a matrix that is used in writing output.

Restriction The array dimensions must match the matrix dimensions. Otherwise, an error occurs.

Tip You can use variable arrays.

See "DS2 Arrays" in *SAS DS2 Programmer's Guide*

Details

The OUT method writes matrix row data to a variable array. Variable arrays can be used to input and output data using an existing DS2 table and output statements. For example, you can read data from a table in matrix form, find the matrix inverse, and write the result matrix to an output table. See the example below.

The OUT method can be overloaded to accept an integer argument that tells which row of a matrix to write to a variable array.

The synonym for the OUT method is the TOVARARRAY method. The following two statements are equivalent:

```
r.tovararray(va, i);
r.out(va, i);
```

The OUT method, which writes data, is often used with the IN method. The IN and OUT methods are overloaded to accept an integer argument that tells which row of a matrix to load. For the IN method, the variable array row data is read into the matrix. For the OUT method, the matrix row data is written to the variable array. In this way, matrices can be loaded and unloaded a row at a time from and to external data storage using variable arrays.

Examples

Example 1

This example writes each row of an inverse to an output table using the variable array *v*.

```
do i=1 to 4;
   inv.out(v, i);
   output;
end;
```

Example 2

Similar to the standard IN method, a complete matrix can also be written to a variable array:

```
vararray double va(3, 3);
dcl package matrix r;

r=_new_ matrix(3, 3);
r.out(va);
```

In this example, a matrix does not need to be written row-by-row. The entire matrix can be written to the variable array. You can use this method in the case where the DS2 output statement (which is row-based) is not being used.

Example 3: Loading and Writing Data

For another example of using the IN and OUT methods, see "Example 2: Multiply Two Matrices That Are Read from External Data" on page 1895.

Example 4: Writing the Entire Matrix to the Array

Similar to the standard LOAD method, a complete matrix can also be written to a variable array:

```
vararray double va[3, 3];
dcl package matrix r;
  r=_new_ matrix(3, 3);
r.out(va);
```

This example shows that matrix data does not need to be written row-by-row. You can write the entire matrix to the array. You could use this technique in a case where the DS2 OUTPUT statement (which is row-based) is not used.

- "Matrix Data Output" in *SAS DS2 Programmer's Guide*

Methods:

- "IN Method" on page 1881
- "OUT Method" on page 1899

Statements:

- "OUTPUT Statement" on page 1400
- "SET Statement" on page 1430

ROWS Method

Returns the number of rows in the specified matrix.

Syntax

variable-name=*matrix-package*.**ROWS**( );

Required Arguments

variable-name
specifies the name of a variable that contains the number of rows after the method is complete.

matrix-package
specifies a matrix package to use with the ROWS method.

Example

The following example returns the number of rows and columns in the matrix, **m**.

```
data _null_;
   dcl double a[2, 3];

   method run();
      dcl package matrix m;
      dcl double mr mc;

      a := (1,2,3,4,5,6);

      m=_new_ matrix(a, 2, 3);
      mr=m.rows();
      mc=m.cols();
      put mr=;
      put mc=;

   end;
run;
```

The following lines are written to the SAS log.

```
mr=2
mc=3
```

See Also

- "Using the MATRIX Package" in *SAS DS2 Programmer's Guide*

Methods:

- "COLS Method" on page 1858

SQRT Method

Returns a matrix that contains the square root of each value in the input matrix.

Syntax

r=*matrix-package*.**SQRT**( );

Required Arguments

r
specifies a matrix that contains the square root of each value in the input matrix.

matrix-package
specifies a matrix package to use with the SQRT method.

See Also

"Matrix Operations" in *SAS DS2 Programmer's Guide*

SUB Method

Subtracts one matrix from another.

Syntax

r=*matrix-package-1*.**SUB**(*matrix-package-2*);

Required Arguments

r
specifies the matrix that is automatically created by the SUB method.

matrix-package-1
specifies the name of the first matrix package that is used in the subtraction operation.

matrix-package-2
specifies the name of the second matrix package that is used in the subtraction operation.

Details

The matrix dimensions for the SUB method must be the same size in order for the matrix subtraction to take place. Each [i, j] element in the first matrix is subtracted from its corresponding [i, j] element in the second matrix.

If you subtract matrices that have missing values, you do not receive an error.

It is also possible to perform scalar subtraction by using a 1x1 matrix.

Example

Here is an example of using the SUB method to subtract two matrices.

```
data _null_;
   dcl double c[3,3];
   dcl double d[1,1];
   dcl double f[3,3];
   method run();
      dcl package matrix m3;
      dcl package matrix m4;
      dcl package matrix r;
      dcl double i j;

      c := (-0, 0, -1, 1, -2.2, 2.2, -3.3, 4.4, 5.5);
      d := (1);

      m3 = _new_ matrix(c, 3, 3);
      m4 = _new_ matrix(d, 1, 1);

      r = m3.sub(m4);
      r.toarray(f);

      do i = 1 to 3;
         do j = 1 to 3;
            put f[i,j];
         end;
      end;
   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
-1
-1
-2
0
-3.2
1.2
-4.3
3.4
4.5
```

See Also

- "Matrix Operations" in *SAS DS2 Programmer's Guide*

Methods:

■ “ADD Method: Matrix Package” on page 1835

TOARRAY Method

Moves the values from a matrix package into a DS2 array.

Syntax

array-name.**TOARRAY**(*matrix-package*);

Required Arguments

array-name
specifies the name of an array to which matrix values are moved.

matrix-package
specifies the matrix package from which values are moved into an array.

Details

You use the TOARRAY method to move values from a matrix to a DS2 array. The array can then be used directly in a DS2 program.

Note: You can also move values to a variable array by using the TOVARARRAY method.

Example

This example moves the values from a matrix into a DS2 array.

```
data _null_;
   dcl double a[3,3];
   dcl double c[3,3];

   method init();
      dcl double i j;
      dcl package matrix m;

      a := (1,2,3,4,5,6,7,8,9);

      m=_new_ matrix(a,3,3);
      m.toarray(c);
```

```
      do i=1 to 3;
         do j=1 to 3;
            put c[i,j];
         end;
      end;
   end;
enddata;
run;
```

The resulting array has the following values.

```
1  2  3
4  5  6
7  8  9
```

See Also

- "Matrix Data Output" in *SAS DS2 Programmer's Guide*
- "DS2 Arrays" in *SAS DS2 Programmer's Guide*

Methods:

- "TOVARARRAY Method" on page 1906

TOVARARRAY Method

Moves the values from a matrix package into a variable array.

Syntax

variable-array-name.**TOVARARRAY**(*matrix-package*);

Required Arguments

variable-array-name
specifies the name of a variable array to which matrix values are moved.

matrix-package
specifies the matrix package from which values are moved into a variable array.

Details

You use the TOVARARRAY method to move values from a matrix to a DS2 variable array. The variable array can then be used directly in a DS2 program.

Note: You can also move values to an array by using the TOARRAY method.

Example

This example shows how to move the values from a matrix into a variable array.

```
data _null_;
   dcl double a[3, 3];
   vararray double c[3, 3];

   method run();
      dcl package matrix m;
      dcl double i j;

      a := (1,2,3,4,5,6,7,8,9);

      m=_new_ matrix(a, 3, 3);
      m.tovararray(c);

      do i=1 to 3;
         do j=1 to 3;
            put c[i, j];
         end;
      end;
   end;
run;
```

The resulting array has the following values.

```
1  2  3
4  5  6
7  8  9
```

See Also

- "Matrix Data Output" in *SAS DS2 Programmer's Guide*

Methods:

- "TOARRAY Method" on page 1905

TRANS Method

Returns a matrix that transposes the rows and columns of the input matrix.

Syntax

r=*matrix-package*.**TRANS**( );

Required Arguments

r
specifies the matrix that contains the transposition of the input matrix.

matrix-package
specifies a matrix package to use with the TRANS method.

Details

The TRANS method exchanges the rows and columns of a given matrix producing the transpose of matrix. If $\mathbf{v}$ is the value in the i^{th} row and j^{th} column of matrix, then the transpose of matrix contains $\mathbf{v}$ in the j^{th} row and i^{th} column. If matrix contains n rows and *p* columns, the transpose has *p* rows and *n* columns.

Example

The following example transposes a 3x4 matrix to produce a 4x3 result matrix.

```
data _null_;
   dcl double a[3, 4];
   dcl double b[4, 3];

   method run();
      dcl package matrix m;
      dcl package matrix r;
        dcl double i j;

      a := (1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12);

      m=_new_ matrix(a, 3, 4);
      r=m.trans();

      r.toarray(b);

      do i=1 to 4;
         do j=1 to 3;
            put b[i, j];
         end;
      end;
   end;
enddata;
run;
```

The input matrix is shown here.

```
1   2   3
```

```
4   5   6
7   8   9
10  11  12
```

The transposed, result matrix is shown here.

```
1   5    9
2   6   10
3   7   11
4   8   12
```

DS2 NODEJSON Package Methods, Operators, and Statements

Traversal Methods

These methods enable you to inspect the size of a JSON object or array and navigate to child nodes by index or key, without constructing a path expression.

If a path is known, the FINDNODE method could be used to directly locate the target node. For more information, see the "FINDNODE Method"

Table 21.1 *Traversal Methods*

METHOD	NODE TYPES	DESCRIPTION
LEN	Object, Array	Returns the number of key/value pairs (object) or elements (array).
HASKEY	Object	Tests whether a key exists among the direct children of an object.
FETCHCHILDKEY	Object	Retrieves the key string from a zero-based or negative index.
FETCHCHILDNODE	Object, Array	Retrieves a direct child node by key string or by zero-based (or negative) index.

Type-Testing Methods

Each type-testing method resolves the node identified by this-node and sets an output flag to 1 if the node matches the described type, or 0. The methods return an INTEGER of 0 upon successful completion or nonzero if the node ID cannot be resolved.

The common syntax for the type-testing methods is:

rc = package.**ISxxx**(*this-node*, *is-flag*);

These are the required arguments for the type-testing methods.

Table 21.2 *Required Argument: This-node*

Property	Value
Direction	Input
Data Type	BIGINT
Description	Node ID to test. Passing a null or invalid node ID causes the method to return a nonzero error code.

Table 21.3 *Required Argument: is-flag*

Property	Value
Direction	Output
Data Type	INTEGER
Description	Set to 1 if the type matches otherwise set to 0.

Table 21.4 *ISxxx Methods Used in Type-Testing Methods Syntax*

Method	Sets is-flag to 1 when the node is:
ISOBJECT	a JSON object (`{...}`)
ISARRAY	a JSON array (`[...]`)
ISSTRING	a JSON string, including an empty string.
ISINT	a JSON integer (a number with no decimal point or exponent).
ISFLOAT	A JSON floating-point number that contains a . or exponent.
ISNUMBER	a numeric type, integer or floating-point number.
ISBOOLTRUE	the JSON literal, true.
ISBOOLFALSE	the JSON literal, false.
ISBOOL	true or false.
ISNULL	the JSON literal, null.

This example demonstrates the functionality of the type-testing methods.

```
dcl int rc rc1; dcl bigint nodeid;
rc = jst.findNode(rootid, '["scores"][0]', nodeid);
rc1 = jst.isNumber(nodeid, rc);
if rc = 1 then put 'First score is a number';
rc1 = jst.isInt(nodeid, rc);
if rc = 1 then put 'First score is an integer';
rc1 = jst.isFloat(nodeid, rc);
if rc = 1 then put 'First score is a float';
```

Value-Retrieval Methods

Each value-retrieval method resolves the node identified by this-node and copies its value into an output variable. The methods return an INTEGER of 0 upon successful completion. Calling a retrieval method on a node whose type does not match returns a nonzero error status.

The syntax for the value-retrieval methods is:

rc=package.**getxxx**(*this-node, get-var*);

These are value-retrieval methods:

Table 21.5 *VALUE-RETRIEVAL METHODS*

Method	get-var TYPE	ACCEPTED NODE TYPES	DESCRIPTION
GETSTRING	NVARCHAR/ VARCHAR	STRING	UTF-8 string value of the node.
GETINT	INTEGER	INTEGER	Value as a 32-bit signed integer. Fails on overflow.
GETBIGINT	BIGINT	INTEGER, FLOAT	Value as a 64-bit signed integer; float is truncated toward zero. Fails on overflow.
GETLONG	BIGINT	INTEGER, FLOAT	Alias for GETBIGINT.
GETFLOAT	DOUBLE	INTEGER, FLOAT	Floating-point value.
GETNUMBER	DOUBLE	INTEGER, FLOAT	Any numeric value as a double.
GETBOOL	INTEGER	BOOLEAN	1 for true, 0 for false.

These are required arguments for value-retrieval methods:

Table 21.6 REQUIRED ARGUMENT: THIS-NODE

PROPERTY	VALUE
Direction	Input
Data type	BIGINT
Description	Node ID of the node whose value is retrieved. Passing a null or invalid node ID causes the method to return a nonzero error code.

Table 21.7 REQUIRED ARGUMENT: GET_VAR

PROPERTY	VALUE
Direction	Output
Data Type	Varies by method
Description	Receives the value of the node. Undefined if the method returns a nonzero error status.

Dictionary

DECLARE PACKAGE Statement: NODEJSON Package

Declares an instance of the NODEJSON package.

Category: Local

Syntax

DECLARE PACKAGE NODEJSON *variable*();

Required Argument

variable
specifies a variable name that can reference an instance of the NODEJSON package.

Example

```
dcl package nodejson jst();
```

FETCHCHILDKEY Method

Specifies the key string at a given index within a JSON object.

Note: The returned value for the FETCHCHILDKEY method is an integer: 0 signifies success, a nonzero integer signifies that the node ID cannot be resolved or the index is out of range.

Syntax

rc=package.**FETCHCHILDKEY**(*this-node*,*key-idx*,key-str);

Required Arguments

this-node
specifies the node ID of the object.

Type BIGINT

key-idx
specifies a zero-based index of the key that is retrieved. A negative index counts from -1 being the end key, -2 is the second to last ....

Type BIGINT

key-str
specifies the key name.

Type NVARCHAR VARCHAR

Example

This example demonstrates the functionality of the FETCHCHILDKEY method.

```
dcl bigint i nkeys;
dcl nvarchar(256) kstr;
rc = jst.len(rootid, nkeys);
do i = 0 to nkeys - 1;
    rc = jst.fetchChildKey(rootid, i, kstr);
    put kstr=;
end;
```

FETCHCHILDNODE Method

Retrieves a direct child node from a JSON object or JSON array

Syntax

FORM 1: rc=package.**FETCHCHILDNODE**(*this-node*,key-str,node-id);

FORM 2: rc=package.**FETCHCHILDNODE**(*this-node*,*key-idx*,*node-id*);

Required Arguments

this-node

FORM 1: Node ID of the JSON object.

FORM 2: Node ID of the JSON object or array.

Data type BIGINT

Note Direction: Input

key-str

specifies a key value that is associated with a node.

Data type VARCHAR NVARCHAR

Note Direction: Input

key-idx

specifies a zero-based index. A negative index counts from the end: -1 is the last element, -2 is the second-to-last, ...

Data type BIGINT

Note Direction: input

node-id

FORM 1: specifies the node ID of the value associated with key-str.

Form 2: specifies the node ID of the child element at the key-idx position .

Data type BIGINT

Note	Direction: Output

Details

JSON Object

The FETCHCHILDNODE method can retrieve a child element from a JSON object. The child element can be accessed by its key string or by its zero-based position. The position of each key/value pair is determined by the order in which the pairs appear in the original serialized JSON text.

The return value for FETCHCHILDNODE (JSON Object) is an integer: 0 signifies a successful completion. A nonzero integer signifies that the node ID cannot be resolved or the key is not present in the object.

JSON Array

The FETCHCHILDNODE method can retrieve a child element from a JSON array. The child element is accessed by its numeric index.

The return value for FETCHCHILDNODE (JSON Array) is an integer: 0 signifies a successful completion. A nonzero integer signifies that the node ID cannot be resolved or the index is out of range.

Usage Notes

Use FETCHCHILDNODE with a key string when you know the key name of an object member.

Use FETCHCHILDNODE with a numeric index to iterate over an object or to access array elements by position.

Comparisons

Depth: FETCHCHILDNODE moves one level down the tree (direct children only); FINDNODE evaluates a multi-step path and can traverse multiple levels in a single call.

Input: FETCHCHILDNODE accepts either a plain key string or a plain integer index; FINDNODE accepts a bracket-notation-path expression such as `'["key"][0]["nested"]'`.

Overload dispatch: The DS2 compiler selects the overload based on the declared type of the second argument. VARCHAR or NVARCHAR invokes the key-string overload. BIGINT invokes the index overload. Declare the variable with the correct type to avoid a type-mismatch error at compile time.

Example

This example demonstrates the FETCHCHILDNODE functionality.

```
dcl bigint child;
dcl bigint i asize;
dcl double fval;

/* Fetch an object value by key name */
rc = jst.fetchChildNode(rootid, 'name', child);

/* Fetch the value of the second key (index 1) in an object */
rc = jst.fetchChildNode(rootid, 1, child);
rc1 = jst.isArray(child, rc);
if rc = 1 then put 'Second value is an array';

/* Iterate over every element in an array */
rc1 = jst.findNode(rootid, '["scores"]', nodeid);
rc1 = jst.len(nodeid, asize);
do i = 0 to asize - 1;
    rc = jst.fetchChildNode(nodeid, i, child);
    rc = jst.getNumber(child, fval);
    put i= fval=;
end;
```

FINDNODE Method

Specifies a JSON node within a parsed tree by evaluating a JSON path expression.

Note: FINDNODE returns a 0 upon successful completion of the method. FINDNODE returns a nonzero integer if the path is invalid, the path does not contain a valid node, or the root ID cannot be resolved.

Syntax

rc = package.**FINDNODE**(*root-id*, *json-path*, *node-id*);

Required Arguments

root-id

The node ID to start navigation. This is typically the root ID returned by PARSEINPUT, but any valid node ID is valid as a subtree root.

Data type BIGINT

Note Direction: Input.

json-path

A path expression that identifies the target node.

Data type VARCHAR NVARCHAR

Note Direction: Input

node-id

specifies the node ID of the matched node. If the method returns a nonzero code the value is undefined.

Data type BIGINT

Note Direction: Output

Details

JSON Path Syntax

The path syntax is a subset of the JSON Path Standard. The bracket notation is only supported. Dot notation (.key) is not supported.

A path is a sequence of one or more steps written without separators. Each step selects one level of the tree:

key

The value of key that is defined within a JSON object.

n

The element at index n within a JSON array. The index is zero-based for nonnegative values. A negative index counts from the end of the array: -1 refers to the last element, -2 the second-to-last, ...

The leading $ root symbol of the JSON Path standard is optional. All paths are evaluated relative to the node passed as root-id, which might be the root of the full document or any fetched subtree node.

Example

These examples demonstrate the functionality of FINDNODE.

```
/* Navigate object key then nested array and object */
jpath = '["lev0-1"][7][3]["str"]';
rc = jst.findNode(rootid, jpath, nodeid);

/* Navigate to an array element by zero-based index */
jpath = '[0]';
rc = jst.findNode(nodeid, jpath, nodeid1);

/* Navigate to the last element using a negative index */
jpath = '[-1]';
rc = jst.findNode(nodeid, jpath, nodeid1);

/* Optional $ prefix — equivalent to the line above */
```

```
jpath = '$[-1]';
rc = jst.findNode(nodeid, jpath, nodeid1);
```

GETBIGINT Method

Returns the value of the designated result set column as type BIGINT.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETBIGINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETBIGINT** (*index*);

package.**GETBIGINT** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that holds the value of the designated result set column.

Note If the designated result set column's type is not type BIGINT, the column value is converted to type BIGINT and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETBIGINT method returns the value of the designated result set column as type BIGINT. If the designated result set column's type is not type BIGINT, the column value is converted to type BIGINT and then returned.

A run-time error results if the GETBIGINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

- "SETTINYINT Method" on page 2057

GETBOOL Method

Returns a Boolean value that specifies if the node is valid.

Syntax

rc=package.**GETBOOL**(*this-node*,*get-var*);

Required Arguments

this-node
specified node ID.

get-var
specifies an integer value, 1 if the node is true, 0 if the node is false. A failure occurs if the node is not a Boolean.

Example

This example demonstrates the functionality of the GETBOOL method.

```
dcl nvarchar(1024) token;
dcl int    ival;
dcl bigint lval;
dcl double fval;
dcl bigint nodeid;

/* Get a string */
rc = jst.findNode(rootid, '["name"]', nodeid);
rc = jst.getString(nodeid, token);
put token=;

/* Get a 32-bit integer */
rc = jst.findNode(rootid, '["count"]', nodeid);
rc = jst.getInt(nodeid, ival);
put ival=;

/* Get a 64-bit integer */
rc = jst.findNode(rootid, '["scores"][0]', nodeid);
rc = jst.getBigInt(nodeid, lval);
put lval=;

/* Get a float (or any number) */
rc = jst.findNode(rootid, '["scores"][1]', nodeid);
rc = jst.getNumber(nodeid, fval);
put fval=;

/* Get a boolean */
rc = jst.findNode(rootid, '["active"]', nodeid);
rc = jst.getBool(nodeid, ival);
put ival=;    /* 1 = true, 0 = false */
run;
```

GETFLOAT Method

Specifies floating-point values that represent nodes.

Syntax

rc=package.**GETFLOAT**(*this-node*,*get-var*);

Required Arguments

this-node
specifies a node ID.

get-var
specifies the floating-point value as a double. Integer and floating-point values for nodes are accepted.

GETINT Method

Returns an integer value of the node if it is valid.

Data type: Integer

Notes: GETINT specifies node IDs that are integer and floating-point values. A floating-point value is truncated toward 0.

An error message is generated if the node value is not an integer or if the value overflows a 32-bit signed integer.

Syntax

rc=package.**GETINT**(*this-node*,*get-var*);

Required Arguments

this-node
specifies the node ID.

get-var
specifies the node value as an integer or floating-point.

GETLONG Method

Returns a long-integer value of the node if it is valid.

Data type: BIGINT

Note: The return value for GETLONG is an integer: 0 signifies successful completion, nonzero signifies that the node is not a number or the value overflows a 64-bit signed integer.

Syntax

rc=package.**GETLONG**(*this-node*,*get-var*);

Required Arguments

this-node
specifies a node ID.

get-var
specifies a node; the node can be an integer or a floating-point value.

Note: The floating-point value is truncated toward 0.

GETNUMBER Method

Specifies numeric integer or floating-point values as a double.

Syntax

rc=package.**GETNUMBER**(*this-node*,*get-var*);

Required Arguments

this-node
specifies a node ID.

get-var
specifies an integer or floating-point value as a double value.

GETSTRING Method

Specifies the UTF-8 string value of the node.

Data type: VARCHAR NVARCHAR

Note: An error message is generated if the node-ID-value is not a UTF-8 string, including null, Boolean, and numeric node values.

Syntax

rc=package.**GETSTRING**(*this-node*,*get-var*);

Required Arguments

this-node
specifies the node ID.

get-var
Receives the UTF-8 string value of the node.

HASKEY Method

Determines whether a JSON object contains a specific key among its direct children. Nested keys at deeper levels of the tree are not searched.

Note: The returned value for the HASKEY method is an integer: 0 signifies success, a nonzero integer signifies that the node ID cannot be resolved.

Syntax

rc=package.**HASKEY**(*this-node*,*key-str*,*has-key*);

Required Arguments

this-node
Node ID of the object to test.

key-str
The key string to look for. An empty string is a valid key.

has-key
Set this value to 1 if the key is present, 0 if it is not present.

Example

This example demonstrates the functionality of the HASKEY method.

```
dcl int haskey;
rc = jst.hasKey(rootid, 'name', haskey);
if haskey = 1 then put 'Object has key "name"';
run;
```

LEN Method

Returns the number of children in a JSON object, key-value pairs, or array elements.

Note: The returned value for the LEN method is an integer: 0 signifies success, a nonzero integer signifies that the node ID cannot be resolved or the node is not an object or array.

Syntax

rc=package.**LEN**(this-node,size);

Required Arguments

this-node
Node ID of the JSON object or array to measure.

Data type BIGINT

Note The data direction is: INPUT

size
Specifies the count of key-value pairs (object) or elements (array).

Data type BIGINT

Note The data direction is: OUTPUT

Example

This example demonstrates the functionality of the LEN method.

```
dcl bigint nodesize;

/* Number of top-level keys in an object */
rc = jst.len(rootid, nodesize);
put nodesize=;

/* Number of elements in an array */
rc1 = jst.findNode(rootid, '["scores"]', nodeid);
rc  = jst.len(nodeid, nodesize);
put nodesize=;   /* prints 3 for [95,87,100] */
run;
```

PARSEINPUT Method

Parses the JSON text and builds an in-memory value tree.

Note: PARSEINPUT returns an integer value. The integer 0 signifies a successful operation. A nonzero value signifies a failure, for example: empty input, parse error, or memory allocation failure.

Syntax

rc=package.**PARSEINPUT**(*json-text*, *root-id*);

Required Arguments

json-text

specifies JSON text to parse. Must be a non-empty UTF-8 encoded string.

Data type VARCHAR NVARCHAR

Note Direction: Input

root-id

specifies the node ID of the root node of the parsed tree. Pass this value to findNode or the traversal methods.

Data type BIGINT

Note Direction: Output

Details

Each call to PARSEINPUT allocates a new value tree and adds it to the package instance's internal list. Multiple trees might coexist within a single package instance. The root ID uniquely identifies both the tree and the top-level node.

Example

This example demonstrates the functionality of PARSEINPUT.

```
dcl package nodejson jst();
dcl bigint rootid;
dcl int rc;
dcl varchar(65536) jtxt;
```

```
jtxt = '{"name":"Alice","scores":[95,87,100]}';
rc = jst.parseInput(jtxt, rootid);
if rc ne 0 then put 'ERROR: parseInput failed, rc=' rc;
run;
```

DS2 PCRXFIND Package Methods, Operators, and Statements

Dictionary

DECLARE PACKAGE Statement: PCRXFIND Package

Creates a package variable and gives you the option of creating an instance of the PCRXFIND package.

Category: Local

Tip: The PACKAGE statement is not required for a PCRXFIND package.

Syntax

DECLARE PACKAGE PCRXFIND *variable* ([*regular-expression*]);

Required Argument

variable
specifies a name that can reference an instance of the PCRXFIND package.

Optional Argument

regular-expression
specifies a regular expression in the form of */expression/flags*. These regular expression *flags* are supported:

i
case insensitive – Allows a case-insensitive expression match within a string.

m
multiple lines – Treats the string as a set of multiple lines. Allows the first character match or last character match to occur next to embedded newline characters.

n
non-capturing – Disables numbered capturing parenthesis.

s
single line – Treats a string as a single long line. Allows the match of a single character (.) to include a newline character.

x
extends your pattern by allowing whitespace characters (tab, newline, carriage return, and form feed characters) and comments in your match.

Data type VARCHAR

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a PCRXFIND package to search for a particular string of text, a *regular-expression*, in another string of text. The PCRXFIND package is predefined for DS2 programs.

You declare a PCRXFIND package by using the DECLARE PACKAGE statement. After you declare the new PCRXFIND package, you can parse a Perl-compatible

regular expression. (Optional) This expression can be passed in when the package is declared. The loaded expression can then be used to perform match operations by providing the indexes of the beginning and ending of the match, as well as indexes related to each parenthetical capture group within the previously parsed regular expression.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement. Each package instance represents a completely separate copy of the package.

There are three ways to construct an instance of a PCRXFIND package.

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package pcrxfind finder(<'regular-expression'>);
```

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package pcrxfind finder;
finder = _new_ pcrxfind(<'regular-expression'>);
```

- Use the DECLARE PACKAGE statement without an expression:

```
declare package pcrxfind finder;
finder = _new_ pcrxfind();
```

See Also

Operators:

- "_NEW_ Operator: PCRXFIND Package" on page 1946

GETGROUP Method

Stores the text represented by the given capture group based on the previous match into the user-supplied resultString.

Requirement: You must have a successful match (returns an index) using the MATCH method before using the GETGROUP method. Using the GETGROUP method without a successful match causes an error and stops program execution.

Syntax

returnCode=*package*.**GETGROUP** (IN_OUT *resultString*, *groupNumber*);

Required Arguments

package
specifies an instance of the PCRXFIND package variable.

groupNumber
specifies the number of the capture group whose text is stored in the *resultString*.

Data type INTEGER

resultString
specifies the string to store the contents of the group in.

Data type VARCHAR

Returned Values

returnCode
specifies a status indicator.

0
indicates successful execution.

–1
indicates the specified capture group was not involved in the previous match.

Data type INTEGER

Details

The GETGROUP method stores the text of the specified capture group into the given string.

See Also

Methods:

- “GETGROUPEND Method” on page 1935
- “GETGROUPLENGTH Method” on page 1936
- “GETGROUPSTART Method” on page 1937

GETGROUPEND Method

Returns the ending index of the given capture group.

Requirement: You must have a successful match using the MATCH method before using the GETGROUPEND method. Using the GETGROUPEND method without a successful match causes an error and stops program execution.

Syntax

ending-index=*package*.**GETGROUPEND** (*groupNumber*) returns int;

Required Arguments

groupNumber
specifies the number of the capture group.

Data type INTEGER

package
specifies an instance of the PCRXFIND package variable.

Returned Values

ending-index
returns the next position in the string after the given capture group.

1 or greater
specifies the ending position.

-1
indicates the specified capture group was not involved in the previous match.

Data type INTEGER

Details

The GETGROUPEND method returns the position in the string after the match or capture group. It adds the length to the starting index.

```
int endIndex = rx.getGroupStart(n) + rx.getGroupLength(n);
```

See Also

Methods:

- "GETGROUP Method" on page 1933
- "GETGROUPLENGTH Method" on page 1936
- "GETGROUPSTART Method" on page 1937

GETGROUPLENGTH Method

Returns the length of the given capture group's text in characters.

Requirement: You must have a successful match using the MATCH method before using the GETGROUPLENGTH method. Using the GETGROUPLENGTH method without a successful match causes an error and stops program execution.

Syntax

length=*package*.**GETGROUPLENGTH** (*groupNumber*);

Required Arguments

package
specifies an instance of the PCRXFIND package variable.

groupNumber
specifies the number of the capture group.

Data type INTEGER

Returned Values

length
specifies the variable to hold the number of characters of the given capture group's text.

1 or greater
specifies the length of the text for the given capture group.

-1
indicates that the specified capture group was not involved in the previous match.

Data type INTEGER

Example

For an example, see "Using the PCRXFIND Package" in *SAS DS2 Programmer's Guide*.

See Also

Methods:

- "GETGROUP Method" on page 1933
- "GETGROUPEND Method" on page 1935
- "GETGROUPSTART Method" on page 1937

GETGROUPSTART Method

Returns the starting index of the given capture group.

Requirement: You must have a successful match using the MATCH method before using the GETGROUPSTART method. Using the GETGROUPSTART method without a successful match causes an error and stops program execution.

Syntax

starting-index=*package*.**GETGROUPSTART** (*groupNumber*);

Required Arguments

groupNumber
specifies the number of the capture group.

Data type INTEGER

package
specifies an instance of the PCRXFIND package variable.

Returned Values

starting-index
specifies the starting index for the previous match.

1 or greater
specifies the starting position.

-1
indicates that the specified capture group was not involved in the previous match.

Data type INTEGER

See Also

Methods:

- "GETGROUP Method" on page 1933
- "GETGROUPLENGTH Method" on page 1936
- "GETGROUPEND Method" on page 1935

GETMATCH Method

Places the text of the previous match into the result string.

Requirement: You must have a successful match using the MATCH method before using the GETMATCH method. Using the GETMATCH method without a successful match causes an error and stops program execution.

Note: See "Predefined DS2 Packages" in *SAS DS2 Programmer's Guide* for more information and examples.

Syntax

returnCode=*package*.**GETMATCH** (IN_OUT *resultString*);

Required Arguments

package
specifies an instance of the PCRXFIND package variable.

resultString
specifies the string to store the contents of the match in.

Data type VARCHAR

Returned Values

returnCode
specifies a status indicator.

0
indicates successful execution.

Data type Integer

Details

The GETMATCH method stores the contents of the previous match into the given string.

See Also

Methods:

- "GETMATCHEND Method" on page 1939
- "GETMATCHLENGTH Method" on page 1941
- "GETMATCHSTART Method" on page 1942

GETMATCHEND Method

Returns the next position after the end of the text from the previous match.

Requirement: You must have a successful match using the MATCH method before using the GETMATCHEND method. Using the GETMATCHEND method without a successful match causes an error and stops program execution.

Syntax

ending-index=package.**GETMATCHEND**();

Required Argument

package
specifies an instance of the PCRXFIND package variable.

Returned Values

ending-index
specifies the position after the last character of the matched string.

2 or greater
Two or greater is returned for the first value after the matched string.

-1
indicates that the specified capture group was not involved in the previous match.

Data type INTEGER

Details

Use the GETMATCHEND method to determine the first position after the matched string within the subject string. This enables you to easily start your next search from the point where the matched string ends.

Example

This example searches a line of text using a regular expression. The GETMATCHEND method returns the index of the next position after the end of the matched string.

```
data regex_test/overwrite=yes;
   dcl char(20) text regex;
   dcl double parse_rc match_rc next_search_start;
   method run();
      dcl package pcrxfind prxf();
      text='quick brown fox';
      regex='/brown/';
      parse_rc=prxf.parse(regex);
      if parse_rc=0 then do;
         match_rc=prxf.match(text);
         if match_rc>0 then do;
            next_search_start=prxf.getmatchend();
            put next_search_start=;
         end;
      end;
   end;
enddata;
run;
```

The following line is written to the SAS log.

```
next_search_start=12
```

See Also

Methods:

- “GETMATCH Method” on page 1938
- “GETMATCHLENGTH Method” on page 1941

- “GETMATCHSTART Method” on page 1942

GETMATCHLENGTH Method

Returns the number of characters of the previous match.

Requirement: You must have a successful match using the MATCH method before using the GETMATCHLENGTH method. Using the GETMATCHLENGTH method without a successful match causes an error and stops program execution.

Syntax

length=*package*.**GETMATCHLENGTH** ();

Required Argument

package
specifies an instance of the PCRXFIND package variable.

Returned Values

length
specifies the number of characters of the matched string. Length can be one of these values:

1 or greater
the number of characters of the matched string.

-1
indicates that the specified capture group was not involved in the previous match.

Data type Integer

Details

The GETMATCHLENGTH method

See Also

Methods:

- “GETMATCH Method” on page 1938

- "GETMATCHEND Method" on page 1939
- "GETMATCHSTART Method" on page 1942

GETMATCHSTART Method

Returns the starting index of the previous match operation.

Requirement: You must have a successful match using the MATCH method before using the GETMATCHSTART method. Using the GETMATCHSTART method without a successful match causes an error and stops program execution.

Syntax

starting-index=*package*.**GETMATCHSTART**();

Required Argument

package
specifies an instance of the PCRXFIND package variable.

Returned Values

starting-index
specifies the position of the first character of the matched string. This is the same value as the previous call to the MATCH method.

1 or greater
one or greater is returned for the starting index.

-1
indicates that the specified capture group was not involved in the previous match.

Data type INTEGER

Details

The GETMATCHSTART method is used to determine the beginning position of the matched string within the subject string

See Also

Methods:

- "GETMATCH Method" on page 1938
- "GETMATCHEND Method" on page 1939
- "GETMATCHLENGTH Method" on page 1941

MATCH Method

Performs a match operation using the previously parsed regular expression.

Syntax

returnCode=*package*.**MATCH** (VARCHAR *subjectString*, [*offset-index*]) returns int;

Required Arguments

package
specifies an instance of the PCRXFIND package variable.

subjectString
specifies the character string to perform the regular expression against.

Data type VARCHAR

Optional Argument

offset-index
specifies an optional index to start the regular expression from.

Data type INTEGER

Returned Values

returnCode
specifies a status indicator.

1 or greater
returns the index where the match begins.

-1
indicates successful execution, but no match found.

Data type INTEGER

Details

The MATCH method returns either the index where the match begins or –1 if the regular expression is not found. Calling the MATCH method before parsing a regular expression results in an error. Upon successfully performing a match, methods such as GetGroupStart use the match results in their operation.

Example

This example searches a line of text using a regular expression. The MATCH method returns the index where the match begins.

```
data regex_test/overwrite=yes;
   dcl char(20) text regex;
   dcl double parse_rc match_rc;
   method run();
      dcl package pcrxfind prxf();
      text='quick brown fox';
      regex='/brown/';
      parse_rc=prxf.parse(regex);
      if parse_rc=0 then do;
         match_rc=prxf.match(text);
         put match_rc=;
      end;
    end;
enddata;
run;
```

The following line is written to the SAS log.

```
match_rc=7
```

Statements

- “DECLARE PACKAGE Statement: PCRXFIND Package” on page 1931

PARSE Method: PCRXFIND Package

Compiles a Perl-compatible regular expression that can be used for pattern matching.

Note: SAS has adopted the Perl Compatible Regular Expression (PCRE) for pattern matching character values. For more information, see PCRE - Perl Compatible Regular Expressions.

Syntax

returnCode=*pcrxfind-package*.**PARSE** (*pcrxfind-expression*);

Required Arguments

pcrxfind-expression
specifies a regular expression in the form of */expression/flag1...flagn*.

expression
The pattern used to match a substring within a string.

> **TIP** Backslashes within the *expression* can be used to escape special regular expression characters, such as \w or \d.

> **TIP** The substitution portion of the string does not require backslashes to escape any characters.

flag
These flags can be used to interpret the regular expression:

i
case insensitive — allows a case-insensitive pattern match within a string.

m
multiple lines — treats a string as a set of multiple lines. Allows the first character match or last character match to occur next to embedded newline characters.

n
non-capturing — prevents the grouping metacharacters () from capturing.

s
single line — treats a string as a single long line. Allows the match of a single character (.) to include the newline character.

x
match extension — allows whitespace characters (tab, newline, carriage return, and form feed characters) and comments in your match.

Restriction The matching mode modifiers p, o, c, a, and l are not supported.

pcrxfind-package
specifies an instance of the PCRXFIND package.

Returned Values

returnCode
specifies a status indicator.

0
indicates successful execution.

NULL
indicates failure and returns an error message.

Data type Integer

Details

The PARSE method in the PCRXFIND package is used to parse a Perl-compatible regular expression.

Compiling an expression allows the same package to parse using a different expression. A successful parse is required before you can use the MATCH method.

Example

The following example creates a PCRXFIND package and uses PARSE to compile a regular expression that matches phone numbers with the form *(nnn) nnn-nnnn*.

```
dcl package pcrxfind phoneFinder();
method init();
   dcl int rc;
   rc = phoneFinder.parse('/(\(\d{3}\)) \d{3}-\d{4}/');
   if null(rc) then do;
      put 'ERROR: Could not parse the provided expression.';
   end;
end;
```

Statements

- “DECLARE PACKAGE Statement: PCRXFIND Package” on page 1931

NEW Operator: PCRXFIND Package

Constructs an instance of a PCRXFIND package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_ PCRXFIND**([*expression*]);

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Optional Argument

expression
specifies a regular expression used to operate on the input text.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a PCRXFIND package variable using the DECLARE PACKAGE statement. After you declare a PCRXFIND package variable, use the _NEW_ operator to instantiate an instance of the PCRXFIND package and assign the new package instance to the PCRXFIND package variable.

```
declare package PCRXFIND finder;
finder = _new_ PCRXFIND();
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a logger package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package PCRXFIND finder();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

DS2 PCRXREPLACE Package Methods, Operators, and Statements

Dictionary

DECLARE PACKAGE Statement: PCRXREPLACE Package

Creates a package variable and gives you the option of creating an instance of the PCRXREPLACE package.

Category: Local

Syntax

DECLARE PACKAGE PCRXREPLACE *variable* ([*regular-expression*]);

Required Argument

variable
specifies a name that can reference an instance of the PCRXREPLACE package.

Optional Argument

regular-expression
specifies a regular expression in the form of [s]/*expression*/*substitution*/*flags*. *Flags* can consist of one or more of these values:

g
global – Allows an expression match and replacement to occur as many times as possible within a string.

i
case insensitive – Allows a case-insensitive expression match within a string.

m
multiple lines – Treats the string as a set of multiple lines. Allows the first character match or last character match to occur next to embedded newline characters.

n
non-capturing – Disables numbered capturing parenthesis.

s
single line – Treats a string as a single long line. Allows the match of a single character (.) to include a newline character.

x
extends your pattern by allowing whitespace characters (tab, newline, carriage return, and form feed characters) and comments in your match.

Data type VARCHAR

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a PCRXREPLACE package to replace or substitute text using a regular *expression*. The PCRXREPLACE package is predefined for DS2 programs.

You declare a PCRXREPLACE package by using the DECLARE PACKAGE statement. (Optional) You can include the regular expression to associate a PCRXREPLACE package with an expression and substitution text. After you declare the new PCRXREPLACE package, you can use the package to perform substitution operations on strings.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be

created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are three ways to construct an instance of a PCRXREPLACE package.

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package pcrxreplace swapper('/expression/replacementText/<flags>');
```

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package pcrxreplace swapper;
swapper = _new_ pcrxreplace(<regular-expression>);
```

- Use the DECLARE PACKAGE statement without an expression:

```
declare package pcrxreplace swapper;
swapper = _new_ pcrxreplace();
```

See Also

Operators:

- "_NEW_ Operator: PCRXREPLACE Package" on page 1954

APPLY Method

Applies the substitution expression, provided at instantiation time, to the loaded subject data.

Syntax

returnCode=*package*.**APPLY**(IN_OUT *subjectString*, [*numberOfTimes*]);

Required Arguments

package
specifies an instance of the PCRXREPLACE package variable.

subjectString
specifies the subject data.

Data type VARCHAR

Optional Argument

numberOfTimes
specifies the number of times the change will be applied.

Data type INTEGER

Returned Values

returnCode
specifies the variable in which to place the return code.

0
indicates successful execution.

NULL
indicates failure and returns an error message.

Data type INTEGER

Details

The APPLY method replaces a matched set of characters in a string, for a specified number of times.

See Also

Statements

- "DECLARE PACKAGE Statement: PCRXREPLACE Package" on page 1949

PARSE Method: PCRXREPLACE Package

Compiles a Perl-compatible regular expression that can be used for pattern matching.

Note: SAS has adopted the Perl Compatible Regular Expression (PCRE) for pattern matching character values. For more information, see PCRE - Perl Compatible Regular Expressions.

Syntax

returnCode=*pcrxreplace-package*.**PARSE** (*pcrxreplace-expression*);

Required Arguments

pcrxreplace-expression
specifies a regular expression in the form of [s]/*expression*/*substitution-text*/*flag1...flagn*.

expression
The pattern used to match a substring within a string.

> **TIP** Backslashes within the *expression* can be used to escape special regular expression characters, such as \w or \d.

> **TIP** The substitution portion of the string does not require backslashes to escape any characters.

flag
These flags can be used to interpret the expression:

g
global — allows a pattern match and replacement substitution to occur as many times as possible within a string.

i
case insensitive — allows a case-insensitive pattern match within a string.

m
multiple lines — treats a string as a set of multiple lines. Allows the first character match or last character match to occur next to embedded newline characters.

n
non-capturing — prevents the grouping metacharacters () from capturing.

s
single line — treats a string as a single long line. Allows the match of a single character (.) to include the newline character.

x
match extension — allows whitespace characters (tab, newline, carriage return, and form feed characters) and comments in your match.

Restriction The matching mode modifiers p, o, c, a, and l are not supported.

substitution-text
The text used to replace the pattern-matched text in the string.

Data type VARCHAR

pcrxreplace-package
specifies an instance of the PCRXREPLACE package.

Returned Values

returnCode
specifies a status indicator.

0
indicates successful execution.

NULL
indicates failure and returns an error message.

Data type Integer

Details

The PARSE method in the PCRXREPLACE package is used to parse a Perl-compatible regular expression.

Compiling an expression allows the same package to parse using a different expression. A successful parse is required before you can use the APPLY method.

Example: Compiling a Perl Regular Expression

The following example creates a PCRXREPLACE package and uses PARSE to compile a regular expression that converts phone numbers to the form *(nnn) nnn-nnnn*.

```
dcl package pcrxreplace normalizer();
method init();
   dcl int rc;
   rc = normalizer.parse(  '/.*(\d{3}).*(\d{3}).*(\d{4})/($1) $2-$3/' );
   if null(rc) then do;
      put 'ERROR: Could not parse the provided expression.';
   end;
end;
```

NEW Operator: PCRXREPLACE Package

Constructs an instance of a PCRXREPLACE package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_ PCRXREPLACE**([*expression*]);

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Optional Argument

expression
specifies a regular expression used to substitute values on the input text.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a PCRXREPLACE package variable using the DECLARE PACKAGE statement. After you declare a PCRXREPLACE package variable, use the _NEW_ operator to instantiate an instance of the PCRXREPLACE package and assign the new package instance to the PCRXREPLACE package variable.

```
declare package pcrxreplace swapper;
swapper = _new_ pcrxreplace();
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a logger package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package pcrxreplace swapper();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

DS2 RedisCli Package Methods, Operators, and Statements

Overview

The RedisCli package provides a DS2 interface that enables access to a Redis server from your DS2 code. The RedisCli DS2 package provides functionality that is similar to redis-cli, the Redis command line interface. Support for this package starts with 2023.10.

Order of Operation to Establish a Connection

If a connection to a Redis server does not exist when a method is called, RedisCli can obtain the information that it needs to connect to a Redis server in several ways. It can use connect method arguments, obtain default configuration information that is stored in a resource configuration, or use SAS_REDIS_* environment variables.

Here is the order of operation. Note that the first two steps apply only to the connect method.

1. (This applies only to the connect method.)

   The connect method determines whether two arguments are provided. If yes, continue with step 1a. Otherwise, go to step 2.

   a. The second argument is used as a port value.

   b. Determine whether the first argument corresponds to a resource configuration name.

      1. If yes, retrieve the properties that are configured for the resource configuration. These values are stored for use when connecting to a Redis server. If any values are not defined in the resource configuration, the connect method attempts to retrieve those values using environment variables as described in step 4. Go to step 4.

      2. If no, the value is assumed to be a host name. Go to step 4.

2. (This applies only to the connect method.)

   The connect method determines whether only one argument is provided. If yes, go to step 2a. Otherwise, go to step 3.

   a. Determine whether the argument is an integer. If yes, store it as the port value. Go to step 3.

   b. Determine whether argument corresponds to an existing resource configuration name.

      1. If yes, retrieve the properties that are configured for the resource configuration. These values are stored for use when connecting to a Redis server. If any values are not defined in the resource configuration, the connect method attempts to retrieve those values using environment variables as described in step 4.

      2. If no, the value is assumed to be a host name. Go to step 4.

3 The RedisCli method determines whether the default resource configuration (`DefaultRedisResourceCfg`) exists. Note that to use the default resource configuration, it must be named *DefaultRedisResourceCfg*.

   a If yes, retrieve the properties that are configured for the resource configuration. These values are stored for use when connecting to a Redis server. If any values are not defined in the resource configuration, the connect method attempts to retrieve those values using environment variables as described in step 4.

   b If no, go to step 4.

4 The RedisCli method attempts to retrieve values using the following environment variables. Note that if any of these values have been previously obtained using an argument or a configuration resource, those values are used.

   - SAS_REDIS_HOST

     Note: If this environment variable is not defined, the default value, localhost (`127.0.0.1`), is used.

   - SAS_REDIS_PORT

     Note: If this environment variable is not defined, the default value, `6379`, is used.

   - SAS_REDIS_AUTH_USER
   - SAS_REDIS_AUTH_PASS
   - SAS_REDIS_TLS

     Note: If this environment variable is not defined, the default value, `false`, is used.

   - SAS_REDIS_CA_CERT
   - SAS_REDIS_TRUST_CERT_PATH
   - SAS_REDIS_CLIENT_CERT_FILE
   - SAS_REDIS_CLIENT_PRIV_KEY_FILE
   - SAS_REDIS_SERVER_DOMAIN

A connection to a stand-alone Redis server is assumed when not specifying the Cluster connection option by one of the following:

- Calling the clusterConnect method.
- Calling the connect method where the first argument is the name of a Redis System Resource Configuration Definition having its cluster property specified as true.
- The SAS_REDIS_CLUSTER environment variable is set to 1 or true.

The following is an example of the "MOVED" errors that you can encounter when the data is not on the server to which you are connected.

- `ERROR: Line 95: redisInstRunCmd1sWithCallback encountered a failure in HGETALL: MOVED 3047 192.0.2.1:7000`
- `ERROR: Line 95: redisInstRunCmd1sWithCallback encountered a failure.`

  `ERROR: Line 95: d2hgetall encountered a failure in redisInstRunCmd1sWithCallback.`

Dictionary

CLUSTERCONNECT Method

Connects to a Redis Cluster.

Notes: The CLUSTERCONNECT method is not required

By default, the connect method uses the first specified argument as "CONNECT Method". If a resource configuration is not found, the argument is assumed to be a "CONNECT Method". For more information, see "Order of Operation to Establish a Connection".

See: "CONNECT Method"

Syntax

rc=*package*.**clusterConnect**([*host*/*resource-config*] [,*port*]]);

Arguments

rc

specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success

nonzero
indicates failure

package

specifies a name that references the RedisCli package instance.

host

specifies the host name or IP address of a node in the Redis Cluster.

resource-config
specifies the name of a resource configuration that contains the properties required to access a Redis Cluster.

If a resource configuration is not found using the specified value, it is considered a *host* value.

port
specifies the port number on which the Redis server is listening.

Details

Resource Configuration

A resource configuration contains the information that is required to connect to a Redis server using predefined configuration information. Resource configurations are stored with your compute environment (such as SAS Container Runtime or SAS Micro Analytic Service).

The connect method can use the default resource configuration, which is named DefaultRedisResourceCfg. To use this default, the DefaultRedisResourceCfg resource configuration must exist for your compute environment.

For information about how to create a resource configuration, see:

- "Configuring a Connection to a Redis Server" in *SAS Micro Analytic Service: Programming and Administration Guide* in *SAS Micro Analytic Service: Programming and Administration Guide*.
- "Configuring a Redis Connection" in *SAS Container Runtime: Programming and Administration Guide* in *SAS Container Runtime: Programming and Administration Guide*.

Host and Port

If the supplied string argument does not resolve to a resource configuration name, it is used as the Redis server host name. A supplied port number is used as the Redis server port.

Alternatively, you can use the following environment variables to assign a default value to *host* and *port*:

- SAS_REDIS_HOST
- SAS_REDIS_PORT

The default values for host and port are 127.0.0.1 (localhost) with port 6379.

CONNECT Method

Connects to the Redis server.

Note: By default, the connect method uses the first specified argument as resource-config. If a resource configuration is not found, the argument is assumed to be a host. For more information, see "Order of Operation to Establish a Connection".

Syntax

rc=*package*.**CONNECT** ([[*host | resource-config*] [, *port*]]);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Optional Arguments

host
specifies the host name or IP address of the Redis server.

resource-config
specifies the name of a resource configuration that contains the properties required to access a Redis server.

For more information, see "Resource Configuration" on page 1963.

If a resource configuration is not found using the specified value, it is considered a *host* value.

port
specifies the port number on which the Redis server is listening.

Details

Redis Cluster

The Connect method can connect to a Redis Server running in Cluster mode if:

- The Connect method call's first argument is a Redis System Resource Configuration Name that references a configuration definition that has the Cluster boolean set as true.

- The first argument is not a resource name, and the first character of the SAS_REDIS_CLUSTER environment variable's value is: "1", "Y", "T", "t", or "y".

Resource Configuration

A *resource configuration* contains the information that is required to connect to a Redis server using predefined configuration information. Resource configurations are stored with your compute environment (such as SAS Container Runtime or SAS Micro Analytic Service).

The connect method can use the default resource configuration, which is named **`DefaultRedisResourceCfg`**. To use this default, the DefaultRedisResourceCfg resource configuration must exist for your compute environment.

For information about how to create a resource configuration, see one of the following:

- "Configuring a Connection to a Redis Server" in *SAS Micro Analytic Service: Programming and Administration Guide*
- "Configuring a Redis Connection" in *SAS Container Runtime: Programming and Administration Guide*

Host and Port

If the supplied string argument does not resolve to a resource configuration name, it is used as the Redis server host name. A supplied port number is used as the Redis server port.

Alternatively, you can use the following environment variables to assign a default value to *host* and *port*:

- SAS_REDIS_HOST
- SAS_REDIS_PORT

The default values for host and port are 127.0.0.1 (localhost) with port 6379.

User Name and Password

You can use the following environment variables to specify a Redis user name and password. The values that are assigned to these environment variables are used if a resource configuration was not specified or if the resource configuration in use did not include a user name, password, or both.

- SAS_REDIS_AUTH_USER
- SAS_REDIS_AUTH_PASS

When both a user name value and a password value are provided, the specified password is used for the specified user. If only the password is provided, the specified password is applied to the default user on the Redis server.

For more information, see the Redis AUTH command documentation.

Note: See your compute environment documentation (for example, SAS Micro Analytic Service, SAS Compute Server, SAS Container Runtime, and so on) for information about how to set an environment variable.

TLS Security

RedisCli supports Transport Layer Security (TLS) for securing data transmission.

By default, TLS security is disabled in RedisCli. When the Redis server requires TLS, the following environment variables can be used when no resource configuration is provided or if the resource configuration omits some of the required TLS properties.

Environment Variable	Description	Required
SAS_REDIS_TLS	Enables or disables the use of TLS in RedisCli. ■ To enable TLS in RedisCli, set this environment variable to 1. ■ To disable TLS in RedisCli, set this environment variable to 0. By default, TLS is disabled in RedisCli.	Required in order to use TLS in RedisCli.
SAS_REDIS_CA_CERT	Specifies the CA certificate file or bundle file to load and use for validation. **Note:** When in a SAS Viya deployment, the value of the SSLCALISTLOC encryption option should be used. For more information, see "SSLCALISTLOC= System Option" in *SAS Viya Platform Encryption: Data in Motion*.	Required if SAS_REDIS_TRUST_CERT_PATH is not set.
SAS_REDIS_CLUSTER	Species to check this variable.	Required if the RedisClusterOn or RedisClusterOn flags are not set.
SAS_REDIS_TRUST_CERT_PATH	Specifies the directory path where trusted CA certificate files are stored in an OpenSSL-compatible structure. **Note:** When in a SAS Viya deployment, the value of the SSLCACERTDIR encryption option should be used. For more information, see "SSLCACERTDIR= System Option" in *SAS Viya Platform Encryption: Data in Motion*.	Required if SAS_REDIS_CA_CERT is not set.

Environment Variable	Description	Required
SAS_REDIS_CLIENT_CERT_FILE	Specifies the client certificate file for use with a two-way TLS connection. If used, SAS_REDIS_CLIENT_PRIV_KEY_FILE must also be specified.	Required if the server requires a client certificate (two-way TLS).
SAS_REDIS_CLIENT_PRIV_KEY_FILE	Specifies the client private key that is used for authentication in a two-way TLS connection.	Required if SAS_REDIS_CLIENT_CERT_FILE is set.
SAS_REDIS_SERVER_DOMAIN	Specifies the Server Name Indication (SNI).	No

For more information about TLS on a Redis server, see the Redis Security documentation.

About Setting Environment Variables

See your compute environment documentation (for example, SAS Micro Analytic Service, SAS Cloud Analytic Services (CAS), SAS Compute Server, SAS Container Runtime, and so on) for information about how to set an environment variable.

DECLARE PACKAGE Statement: RedisCli Package

Creates a package variable and enables you to create an instance of the RedisCli package.

Syntax

DECLARE PACKAGE REDISCLI *variable*();

Package Variable

variable
specifies a name that references the RedisCli package instance.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a RedisCli package to interface with Redis databases. The RedisCli package is predefined for DS2 programs.

When a package is declared, a variable is created that can reference an instance of the package. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a RedisCli package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package rediscli rds;
rds = _new_ rediscli();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package rediscli rds();
```

Note: Constructing a RedisCli package does not establish a connection to a Redis server. After instantiation, use the "CONNECT Method" to connect to a server.

See Also

- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: RedisCli Package" on page 1976

DELETEKEY Method

Removes the specified key.

Syntax

rc=*package*.**DELETEKEY** (*key*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Argument

key
specifies the string value that identifies the key to remove.

If the specified key does not exist, the command is ignored. An error does not occur if the key does not exist.

DISCONNECT Method

Disconnects from the Redis server.

Syntax

rc=*package*.**DISCONNECT**();

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Details

You do not have to disconnect from a Redis server before you destroy a package instance variable. Here are some examples of how an automatic disconnection can occur:

- When a package instance variable is destroyed.
- When a package instance variable goes out of scope or is set to null, and the DS2 infrastructure performs the garbage collection process.

EXISTS Method

Determines whether a specified key exists.

Syntax

rc=*package*.**EXISTS** (*key*, *isSet*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that identifies the key.

isSet
specifies the variable that is updated to indicate whether the key exists. If the key exists, the *isSet* variable is assigned a value of 1; otherwise, it is assigned a value of 0. This is an IN_OUT argument.

Data type INTEGER

Details

If a specified key does not exist, the value is not a BINARY type, or an error occurs, *isSet* is updated with a missing value.

Example

```
data _NULL_;
   method init();
      declare package rediscli redis();
      declare int rc;
      declare int isSet;
      rc = redis.connect();
      if (rc ^=0) then do;
         put 'Error connecting to redis';
         stop;
      end;
      rc = redis.exists("&key", isSet);
      if (rc ^= 0) then do;
         put 'Error checking if key exists';
         stop;
      end;
   end;
enddata;
```

GETBINARY Method

Gets the specified binary key and its assigned value.

Applies to: RedisCli Package

Syntax

rc=*package*.**GETBINARY** (*key*, *variable*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that identifies the key to retrieve.

variable
specifies the variable that is updated with the retrieved key value. This is an IN_OUT argument.

Data type VARBINARY, BINARY

Note VARBINARY is the preferred data type.

Details

If a specified key does not exist or an error occurs, *variable* is updated with a null value.

Example

Here is an example that uses the GETBINARY method.

```
proc ds2 libs=work;
   data _null_;
      dcl package logger logr( 'App.Test' );
      dcl package rediscli rds();
      method init();
         dcl int rc;
         dcl varchar(64) key;
         dcl varbinary(1) b1 b2;
         dcl int i32;
         rc = rds.connect();
         if rc then logr.log( 'e', 'connect error, rc=$s', rc );
         else do;
             key = 'mykey';
             b1 = x'FF';
             rc = rds.setBinary( key, b1, 'EX', 60 );
             if rc then logr.log( 'e', 'setBinary error, rc=$s', rc );
             else do;
                rc = rds.getBinary( key, b2 );
                if rc then logr.log( 'e', 'getBinary error, rc=$s',
rc );
                else do;
                   i32 = inputn( b2, 'PIB1.' );
                   logr.log( 'd', 'key=$s, i32=$s', key, i32 );
                end;
             end;
          end;
      end;
   enddata;
   run;
```

```
quit;
```

GETSTRING Method

Gets the specified string key and its assigned value.

Applies to: RedisCli Package

Syntax

rc=*package*.**GETSTRING** (*key*, *variable*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that identifies the key to retrieve.

variable
specifies the variable that is updated with the retrieved key value. This is an IN_OUT argument.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR

Details

If a specified key does not exist or an error occurs, *variable* is updated with a missing value.

HGET Method

Retrieves the value associated with the field in the hash that is stored at the specified key.

Syntax

rc=*package*.**HGET** (*key*, *field*, *variable*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that is the unique identifier for the hash.

field
specifies the string value that identifies the field from which to retrieve the value.

variable
specifies the variable that is updated with the retrieved field value. This is an IN_OUT argument.

Data type CHAR, NCHAR, VARCHAR, NVARCHAR, VARBINARY

Details

If a specified key or field does not exist or an error occurs, *variable* is updated with a missing value.

HGETALL Method

Retrieves all fields and values of the hash that is stored at the specified key, and then appends them to the given datagrid.

Syntax

rc=*package*.**HGETALL** (*key*, *datagrid*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string or binary value that is the unique identifier for the hash.

datagrid
specifies the datagrid package instance in which to store fields and values of the hash retrieved from the specified key. Note the following information about this operation:

- The retrieved field-value pairs are appended to the datagrid as an additional row.
- The HGETALL method attempts to match the data type of the existing column. If the value cannot be converted to the data type of the column, the assigned value is missing.
- If a field is retrieved and does not match an existing column, a new column is added to the datagrid.

  The new column is of type string.

Details

A row is not appended to the datagrid if an error occurs or if the specified key does not reference a hash on the Redis server.

HGETSUBSET Method

Adds a row to the given datagrid. Then, for each field in the hash that matches a column in the datagrid, adds the corresponding value to the newly added datagrid row.

Syntax

rc=*package*.**HGETSUBSET** (*key*, *datagrid*);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string or binary value that is the unique identifier for the hash.

datagrid
specifies the datagrid package instance that contains the columns to match and to then append values. Note the following information about this operation:

- The retrieved field values are appended to the datagrid as an additional row.
- The HGETSUBSET method attempts to match the data type of the existing column. If the value cannot be converted to the data type of the column, the assigned value is missing.
- If a field does not exist as a column in the specified datagrid, it is ignored.

Details

A row is not appended to the datagrid if an error occurs or if the specified key does not reference a hash on the Redis server.

HSET Method

Sets the specified fields to their respective values in the hash stored at the specified key.

Syntax

rc=*package*.**HSET** (*key*, *field*, *value*);

Return Value

rc
specifies the variable to hold the return code value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that is the unique identifier for the hash.

field
specifies the string value that identifies the field in which to assign a value.

value
specifies the value to assign to the specified field. You can specify a string, BINARY, VARBINARY, DOUBLE, BIGINT, or INTEGER value.

Note: If a missing numerical value is specified, a zero-length string value is set.

Details

This command overwrites the values of specified fields that exist in the hash. If a key does not exist, a new key holding a hash is created.

NEW Operator: RedisCli Package

Constructs an instance of a RedisCli package.

Syntax

package=**_NEW_REDISCLI**( );

Package Variable

package
specifies a name that references the RedisCli package instance.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

Note: Constructing a RedisCli package does not establish a connection to a Redis server. After instantiation, use the "CONNECT Method" to connect to a server.

You declare a RedisCli package variable using the DECLARE PACKAGE statement. After you declare a RedisCli package variable, use the _NEW_ operator to instantiate an instance of the RedisCli package and assign the new package instance to the RedisCli package variable.

```
declare package rediscli rds;
rds = _new_ rediscli();
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a RedisCli package, you can declare and instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package rediscli rds();
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

See Also

"Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

SELECT Method

Selects the logical database with the specified zero-based numeric index.

Syntax

rc=*package*.**SELECT** ([*logicalDB*]);

Return Value

rc
specifies the variable to hold the return code value. The return code is an INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies the name of the RedisCli package variable.

Optional Argument

logicalDB
specifies the numeric index of the logical database.

Details

If you do not specify the *logicalDB* argument, the value that is assigned to the SAS_REDIS_LOGICAL_DATABASE environment variable is used to select a logical database.

If you do not use the SELECT method, RedisCli connects to the default database. This is either logical database 0 (the default value) or what is specified for the SAS_REDIS_LOGICAL_DATABASE environment variable.

Note: See your compute environment documentation (for example, SAS Micro Analytic Service, SAS Cloud Analytic Services (CAS), SAS Compute Server, SAS Container Runtime, and so on) for information about how to set an environment variable.

SETBINARY Method

Sets a binary value.

Applies to: RedisCli Package

Syntax

rc=*package*.**SETBINARY** (*key*, *value* [,*options* [, *option_value*]]);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that identifies the key.

value
specifies the binary value to assign to the specified key.

Optional Arguments

options
any of the following option strings that modify the behavior of the method. If you specify more than one option, separate each option with a space.

GET
returns the existing BINARY stored at the specified key or null if the key did not exist. An error is returned and the SET operation is terminated if the value that is stored at the key is not a binary.

KEEPTTL
retains the time to live that is associated with the key.

NX | XX
NX sets the key only if it does not already exist. XX sets the key only if it already exists.

EX | PX | EXAT | PXAT
EX sets the expire time, in seconds. PX sets the expire time, in milliseconds.

EXAT sets the UNIX timestamp at which the key expires, in seconds. PXAT sets the UNIX timestamp at which the key expires, in milliseconds.

Note: If you use one of these time-based options, specify it as the last option if other options are also specified. This is required because a time-based option's corresponding *option_value* must immediately follow the option.

option_value
if EX, PX, EXAT, or PXAT is specified, specifies the value to assign to that option. The value that you specify must immediately follow the option, and be preceded by a comma. Here is an example:

```
rc = rds.setBinary( key, value, 'NX EX', 2 );
```

Example

Here is an example that uses the SETBINARY method.

```
proc ds2 libs=work;
   data _null_;
      dcl package logger logr( 'App.Test' );
      dcl package rediscli rds();
      method init();
         dcl int rc;
         dcl varchar(64) key;
         dcl varbinary(1) b1 b2;
         dcl int i32;
         rc = rds.connect();
         if rc then logr.log( 'e', 'connect error, rc=$s', rc );
         else do;
             key = 'mykey';
             b1 = x'FF';
             rc = rds.setBinary( key, b1, 'EX', 60 );
             if rc then logr.log( 'e', 'setBinary error, rc=$s', rc );
             else do;
                rc = rds.getBinary( key, b2 );
                if rc then logr.log( 'e', 'getBinary error, rc=$s',
rc );
```

```
                    else do;
                       i32 = inputn( b2, 'PIB1.' );
                       logr.log( 'd', 'key=$s, i32=$s', key, i32 );
                    end;
                 end;
              end;
           end;
        enddata;
        run;
     quit;
```

SETSTRING Method

Sets a string key and value.

Applies to: RedisCli Package

Syntax

rc=*package*.**SETSTRING** (*key*, *value* [, *options* [, *option_value*]]);

Return Value

rc
specifies the variable to hold the return code value. The return code is a 32-bit INTEGER value.

0
indicates success.

Nonzero
indicates failure.

Package Variable

package
specifies a name that references the RedisCli package instance.

Required Arguments

key
specifies the string value that identifies the key.

value
specifies the string value to assign to the specified key.

Optional Arguments

options

any of the following option strings that modify the behavior of the method. If you specify more than one option, separate each option with a space.

- **GET:** returns the existing binary stored at the specified key or null if the key did not exist. An error is returned and the SET operation is terminated if the value that is stored at the key is not a BINARY.
- **KEEPTTL:** retains the time to live that is associated with the key.
- **NX | XX:** NX sets the key only if it does not already exist. XX sets the key only if it already exists.
- **EX | PX | EXAT | PXAT:** EX sets the expire time, in seconds. PX sets the expire time, in milliseconds.

  EXAT sets the UNIX timestamp at which the key expires, in seconds. PXAT sets the UNIX timestamp at which the key expires, in milliseconds.

  Note: If you use one of these time-based options, specify it as the last option if other options are also specified. This is required because a time-based options corresponding *option_value* must immediately follow the option.

option_value

if EX, PX, EXAT, or PXAT is specified, the value to assign to that option. The value that you specify must immediately follow the option, and be preceded by a comma. Here is an example:

```
rc = rds.setString( key, 'risk1|west|ATM|0123|withdrawal|4', 'NX EX', 2 );
```

Details

You can specify only a single key-value pair. If the value that you specify is formatted as a delimited composite value, use the pipe character (|) as a delimiter. Here is an example that uses a delimited composite value:

```
proc ds2 libs=work;
   data _null_;
      dcl package logger logr( 'App.Test' );
      dcl package rediscli rds( 'my instance name' );
      dcl varchar(64) key strg;
      method init();
         dcl int rc;
         rc = rds.connect();
         key = 'group|region|type|terminal|trans:count';
         rc = rds.setString( key, 'risk1|west|ATM|0123|withdrawal|4',
'NX EX', 2 );
         rc = rds.getString( key, strg );
         if rc then logr.log( 'e', 'getString error, rc=$s', rc );
         else logr.log( 'd', 'getString, key=$s, strg=$s', key, strg );
      end;
   enddata;
```

```
   run;
quit;
```

DS2 SQLSTMT Package Methods, Operators, and Statements

Dictionary

BINDPARAMETERS Method

Binds a list of variables to the parameters in the FedSQL statement.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BINDPARAMETERS** ([*parameter-variable-list*]);

Required Argument

package
specifies an instance of the SQLSTMT package.

Optional Argument

[*parameter-variable-list*]
specifies a variable list or named variable list that contains the variables to bind to the FedSQL statement's parameters.

Requirement: Variables must be in the form of a variable list, which must be enclosed in brackets ([]) or a named variable list.

Tip: The number of variables in the variable list must match the number of parameters in the FedSQL statement.

See: "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*

Details

If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the SQLSTMT package's SET*type* methods.

The BINDPARAMETERS method binds the variables in the specified variable list to the parameters in the FedSQL statement.

Parameter values must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and a SET*type* method is invoked.

If the type of a bound variable differs from the corresponding parameter's type, the bound variable's value is converted to the parameter's type.

The BINDPARAMETERS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

A run-time error also results if the BINDPARAMETERS method is called after the FedSQL statement is executed.

See Also

- "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*

Methods:

- "BINDRESULTS Method" on page 1986
- SET "type" methods in this chapter

BINDRESULTS Method

Binds a list of variables to the columns of the result set of the FedSQL statement.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BINDRESULTS** (*parameter-variable-list*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

parameter-variable-list
specifies a variable list or named variable list that contains the variables to bind to the columns of the result set.

Requirement: Variables must be in the form of a variable list, which must be enclosed in brackets ([]) or a named variable list.

Tip: The number of variables in the variable list must match the number of columns in the result set.

See: "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*

Details

The FETCH method returns the next row of data from the result set. If variables are bound to the result set columns with the BINDRESULTS method, then the fetched data for each result set column is placed in the variable bound to that column. If the type of a variable differs from the corresponding column's type, the column data value is converted to the variable's type.

The result data must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

A run-time error results if the BINDRESULTS method is called after the result data is fetched.

The BINDRESULTS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

- "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*

Methods:

- "BINDPARAMETERS Method" on page 1984
- SET "type" methods in this chapter

BULKINSERTADDROW Method

Adds a row of data for bulk insertion.

Syntax

package.**BULKINSERTADDROW**();

Required Argument

package
specifies an instance of the SQLSTMT package.

Requirement The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

Details

The data for each insertion column is copied from the corresponding variable that is bound by the BULKINSERTBINDCOLUMNS method. If the insertion column's data type does not match the corresponding variable's data type, the copied data value is converted to the insertion column's data type.

A run-time error occurs if you call the BULKINSERTADDROW method before you call the BULKINSERTBINDCOLUMNS method.

The BULKINSERTADDROW method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

"BULKINSERTBINDCOLUMNS Method"

BULKINSERTBINDCOLUMNS Method

Binds a list of variables to the columns that are selected for bulk insertion.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BULKINSERTBINDCOLUMNS**(*variable-list*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

Requirement: The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes: The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION: **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

variable-list
specifies a variable list that contains the variables to bind to the columns.

Requirement: Variables must be in the form of a variable list, which must be enclosed in brackets ([]) or a named variable list.

Tip: The number of variables in the variable list must match the number of columns in the result set.

See: "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*

Details

The number of variables that are specified in *variable-list* must match the number of columns that are selected for bulk insertion. If the insertion column's data type does not match the corresponding variable's data type, the copied data value is converted to the insertion column's data type.

A run-time error occurs if you call the BULKINSERTBINDCOLUMNS method before the bulk insertion statement is prepared by the BULKINSERTPREPARE method.

The BULKINSERTBINDCOLUMNS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

- "BULKINSERTISPREPARED Method"
- "BULKINSERTPREPARE Method"

BULKINSERTFLUSH Method

Flushes all the rows in the bulk insertion row buffer.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BULKINSERTFLUSH**();

Required Argument

package
specifies an instance of the SQLSTMT package.

Requirement: The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes: The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

Details

The BULKINSERTFLUSH method performs a bulk insertion of all of the rows in the current row buffer.

An implicit flush of the current row buffer occurs in any of these scenarios:

- The bulk insertion row buffer is full.
- The SQL statement is deleted.

The BULKINSERTFLUSH method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

A run-time error occurs if you call the BULKINSERTFLUSH method before you call the BULKINSERTBINDCOLUMNS method.

See Also

"BULKINSERTBINDCOLUMNS Method"

BULKINSERTGETCOLUMNCOUNT Method

Returns the number of columns that are selected for bulk insertion.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BULKINSERTGETCOLUMNCOUNT**();

Required Argument

package
specifies an instance of the SQLSTMT package.

Requirement The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

Details

A run-time error occurs if you call the BULKINSERTGETCOLUMNCOUNT method before the bulk insertion statement is prepared by the BULKINSERTPREPARE method.

See Also

- "BULKINSERTISPREPARED Method"
- "BULKINSERTPREPARE Method"

BULKINSERTGETCOLUMNNAME Method

Returns the column name for the bulk insertion column at the specified index.

Restriction: This method is not supported on the CAS server.

Syntax

Form 1: *package*.**BULKINSERTGETCOLUMNNAME**(*index*);

Form 2: *package*.**BULKINSERTGETCOLUMNNAME**(*index*,*variable*,*rc*);

Required Arguments

index
specifies the column to return. The column index is ordered sequentially and starts at 1.

package
specifies an instance of the SQLSTMT package.

Requirement The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result column name is returned.

1
(ERROR) an error occurred during data retrieval.

variable
specifies the variable that will hold the returned column name.

Details

A run-time error occurs if you call the BULKINSERTGETCOLUMNNAME method before the bulk insertion statement is prepared by the BULKINSERTPREPARE method.

See Also

- BULKINSERTISPREPARED
- "BULKINSERTPREPARE Method"

BULKINSERTGETCOLUMNTYPENAME Method

Returns the type name of the bulk insertion column at the specified column index.

Restriction: This method is not supported on the CAS server.

Syntax

Form 1: *package*.**BULKINSERTGETCOLUMNTYPENAME**(*index*);

package.**BULKINSERTGETCOLUMNTYPENAME**(*index*,*variable*,*rc*);

Required Arguments

index

specifies the column to return. The column index is ordered sequentially and starts at 1.

package

specifies an instance of the SQLSTMT package.

Requirement The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

rc

specifies the variable in which to place the return code. The following values are possible:

0

(SUCCESS) the result column type name is returned.

1

(FAILURE) an error occurred during data retrieval.

variable

specifies the variable that will hold the returned column type name.

Details

A run-time error occurs if you call the BULKINSERTGETCOLUMNTYPENAME method before the bulk insertion statement is prepared by the BULKINSERTPREPARE method.

See Also

- "BULKINSERTISPREPARED Method"

■ "BULKINSERTPREPARE Method"

BULKINSERTISPREPARED Method

Returns a value that indicates whether the SQLSTMT package instance is prepared for bulk insertion.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BULKINSERTISPREPARED**();

Required Argument

package
specifies an instance of the SQLSTMT package.

Requirement: The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes: The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION: **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

Details

The BULKINSERTISPREPARED method returns a status indicator. Zero (FALSE) is returned if the SQLSTMT instance is not prepared for bulk insertion; a non-zero value (TRUE) is returned if the SQLSTMT package instance is prepared for bulk insertion.

See Also

"BULKINSERTPREPARE Method"

BULKINSERTPREPARE Method

Prepares an SQLSTMT package instance for a bulk insertion.

Restriction: This method is not supported on the CAS server.

Syntax

package.**BULKINSERTPREPARE**(*select-string*[, *connection-string*]);

Required Arguments

package
specifies an instance of the SQLSTMT package.

Requirement The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

CAUTION **Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used.** For more information, see *SAS FedSQL Language Reference*.

select-string
specifies a string that contains a FedSQL SELECT statement. The string can be a string literal.

Optional Argument

connection-string
contains a fully specified connection string.

Default If a connection string is not provided, the SQLSTMT package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.

Details

The columns that are selected by the FEDSQL SELECT statement specified by the *select-string* argument are selected as the columns for bulk insertion.

The BULKINSERTPREPARE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

"BULKINSERTPREPARE Method"

CLOSERESULTS Method

Releases the result set from the last execution of the statement.

Restriction: This method is not supported on the CAS server.

Syntax

package.**CLOSERESULTS**( );

Required Argument

package
specifies an instance of the SQLSTMT package.

Details

An SQLSTMT instance maintains only one result set. The result set is automatically released when the FedSQL statement is executed or deleted.

The CLOSERESULTS method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

See Also

"Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*

DECLARE PACKAGE Statement: SQLSTMT Package

Creates a package variable and enables you to create an instance of the SQLSTMT package.

Category: Local

Restriction: This statement is not supported on the CAS server.

Note: Braces in the syntax convention indicate a syntax grouping. The escape character (\ ) before a brace indicates that the brace is required in the syntax. *sql-text* must be enclosed in braces ({ }).

Syntax

Form 1: **DECLARE PACKAGE SQLSTMT** *variable* [('*sql-text*' [,\[*parameter-variable-list*\]])];

Form 2: **DECLARE PACKAGE SQLSTMT** *variable* [('*sql-text*' [, *connection-string*])];

Form 3: **DECLARE PACKAGE SQLSTMT** *variable* ( );

Form 4: **DECLARE PACKAGE SQLSTMT** *variable* ;

Required Argument

variable
specifies a name that can reference an instance of the SQLSTMT package.

Optional Arguments

'sql-text'
is a valid FedSQL statement or string variable that contains a FedSQL statement that inserts into, updates, selects from, or deletes rows from a table.

CAUTION
Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used. For more information, see *SAS FedSQL Language Reference*.

Requirement: The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes: The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables used in the SQLSTMT package, rather than the DS2 rules for

identifiers. This occurs because FedSQL parses the string containing the SQL statement rather than DS2.

[*parameter-variable-list*]
specifies variables that are bound to the parameters contained in the FedSQL statement.

Requirements Variables must be in the form of a variable list that must be enclosed in brackets ([]) or a named variable list.

Parameter data must be specified exclusively with either bound variables or exclusively with the SQLSTMT SET*type* methods.

See "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*

connection-string
contains the fully specified connection string.

Default If a connection string is not provided, the SQLSTMT package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.

Note The connection string is a string literal.

Tip A connection string defines how to connect to the data. A connection string identifies the query language to be submitted as well as the information required to connect to the data source or sources.

See This parameter is primarily designed for use with the SAS Federation Server. For more information about creating a fully specified connection string, see the *SAS Federation Server: Administrator's Guide*.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

The SQLSTMT package provides a way to pass FedSQL statements to a DBMS for execution. The FedSQL statements could create, modify, or delete tables. If the FedSQL statements selects rows from a table, the SQLSTMT package provides methods for interrogating the rows returned in a result set. The SQLSTMT package is predefined for DS2 programs.

You declare an SQLSTMT package by using the DECLARE PACKAGE statement. This associates an SQLSTMT package with an SQLSTMT name.

There are two ways to construct an instance of an SQLSTMT package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package sqlstmt sqlpkg;
sqlpkg = _new_ sqlstmt('update db2.dataset2 set y=? where x=?',[y x]);
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package sqlstmt sqlpkg('update db2.dataset2 set y=? where x=?',[y x]);
```

If the DECLARE statement includes arguments for construction within its parentheses (and no arguments is valid for the SQLSTMT package), then the package instance is allocated. If no parentheses are included, then a variable is created but the package instance is not allocated.

When an SQLSTMT instance is created with SQL text (Forms 1 and 2), the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the SQLSTMT package's SET*type* methods. The DECLARE PACKAGE statement binds the variables in the optional variable list to the parameters in the FedSQL statement.

When an SQLSTMT instance is created without FedSQL text (Form 3), the SQLSMT instance is allocated and left in an unprepared state. Use the PREPARE method to prepare the FedSQL statement at a later time.

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

For more information about SQLSTMT packages, see "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*.

- "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*

Methods:

- "BINDPARAMETERS Method" on page 1984
- "PREPARE Method" on page 2035
- SET "type" methods in this chapter

Operators:

- "_NEW_ Operator: SQLSTMT Package" on page 2033

DELETE Method: SQLSTMT Package

Deletes an instance of the SQLSTMT package.

Restriction: This method is not supported on the CAS server.

Note: The DELETE method is not required. When no SQLSTMT package variables reference an SQLSTMT package instance, the package instance is automatically deleted.

Syntax

package.**DELETE**( );

Required Argument

package
specifies an instance of the SQLSTMT package variable.

Details

When you no longer need the SQLSTMT package, delete it by using the DELETE method. If you attempt to use an SQLSTMT package after you delete it, an error will be written to the log.

See Also

- "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

EXECUTE Method

Executes the FedSQL statement.

Restriction: This method is not supported on the CAS server.

Syntax

package.**EXECUTE**( );

Required Argument

package
specifies an instance of the SQLSTMT package.

Details

The EXECUTE method executes the FedSQL statement and returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error; 2 is returned if there is no data (NODATA). The NODATA condition exists when a FedSQL UPDATE or DELETE statement does not affect any rows.

An SQLSTMT instance maintains only one result set. The result set from the previous execution, if any, is released before the FedSQL statement is executed.

The FedSQL statement executes dynamically at run time. Because the statement is prepared at run time, it can be built and customized dynamically during the execution of the DS2 program.

See Also

"Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*

FETCH Method

Fetches the next row of data from the result set of the FedSQL statement.

Restriction: This method is not supported on the CAS server.

Syntax

package.**FETCH** ([*result-variable-list*]);

Required Arguments

package
specifies an instance of the SQLSTMT package.

[*result-variable-list*]
specifies a variable list that contains the variables to bind to the columns of the result set.

Details

The FETCH method returns the next row of data from the result set. A status indicator is returned. Zero is returned for successful execution; 1 is returned if there is an error; 2 is returned if there is no data (NODATA). The NODATA condition exists if the next row to be fetched is located after the end of the result set.

If variables are bound to the result set columns with the BINDRESULTS method or by the FETCH method, then the fetched data for each result set column is placed in the variable bound to that column. If the variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

A run-time error results if FETCH is called before the statement is executed.

An SQLSTMT instance maintains only one result set. The result set from the previous execution, if any, is released before the FedSQL statement is executed. You can also use the CLOSERESULTS method to release the result set at any time.

See Also

- "Using the SQLSTMT Package" in *SAS DS2 Programmer's Guide*

Methods:

- "BINDRESULTS Method" on page 1986
- GET "type" methods in this chapter

GETBIGINT Method

Returns the value of the designated result set column as type BIGINT.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETBIGINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETBIGINT** (*index*);

package.**GETBIGINT** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that holds the value of the designated result set column.

Note If the designated result set column's type is not type BIGINT, the column value is converted to type BIGINT and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETBIGINT method returns the value of the designated result set column as type BIGINT. If the designated result set column's type is not type BIGINT, the column value is converted to type BIGINT and then returned.

A run-time error results if the GETBIGINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETBINARY Method

Returns the designated result set column as type BINARY.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETBINARY method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the *rc* status indicator.

Syntax

variable=*package*.**GETBINARY** (*index*);

package.**GETBINARY** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type BINARY, the column value is converted to type BINARY and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETBINARY method returns the value of the designated result set column as type BINARY. If the designated result set column's type is not type BINARY, the column value is converted to type BINARY and then returned.

A run-time error results if the GETBINARY method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETCHAR Method

Returns the designated result set column as type CHAR.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the *rc* status indicator.

Syntax

variable=*package*.**GETCHAR** (*index*);

package.**GETCHAR** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type CHAR, the column value is converted to type CHAR and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETCHAR method returns the value of the designated result set column as type CHAR. If the designated result set column's type is not type BIGINT, the column value is converted to type CHAR and then returned.

A run-time error results if the GETCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETCOLUMNCOUNT Method

Returns the number of columns in the result set.

Restriction: This method is not supported on the CAS server.

Syntax

variable=*package*.**GETCOLUMNCOUNT**();

Required Arguments

variable
specifies the variable that will hold the number of columns in the result set.

package
specifies an instance of the SQLSTMT package.

Details

A run-time error occurs if the GETCOLUMNCOUNT method is called before the SQLSTMT is prepared.

See Also

Methods:

- “GETCOLUMNNAME Method” on page 2008
- “GETCOLUMNTYPENAME Method” on page 2009

GETCOLUMNNAME Method

Returns the column name of the result set column with the designated index.

Restriction: This method is not supported on the CAS server.

Syntax

variable=*package*.**GETCOLUMNNAME**(*index*);

package.getColumnName(*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the name of the designated result set column.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

Details

A run-time error occurs if the GETCOLUMNNAME method is called before the SQLSTMT is prepared.

See Also

Methods:

- “GETCOLUMNCOUNT Method” on page 2007
- “GETCOLUMNTYPENAME Method” on page 2009

GETCOLUMNTYPENAME Method

Returns the data type of the result set column with the designated index.

Restriction: This method is not supported on the CAS server.

Syntax

variable=*package*.**GETCOLUMNTYPENAME**(*index*);

package.getColumnTypeName(*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the data type of the result set column.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

Details

GETCOLUMNTYPENAME returns only the data types that are supported by DS2. For more information, see "DS2 Data Types" in *SAS DS2 Programmer's Guide*.

A run-time error occurs if the GETCOLUMNTYPENAME method is called before the SQLSTMT is prepared.

See Also

Methods:

- "GETCOLUMNCOUNT Method" on page 2007

■ "GETCOLUMNTYPENAME Method" on page 2009

GETDATE Method

Returns the designated result set column as type DATE.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETDATE method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETDATE** (*index*);

package.**GETDATE** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type DATE, the column value is converted to type DATE and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETDATE method returns the value of the designated result set column as type DATE. If the designated result set column's type is not type DATE, the column value is converted to type DATE and then returned.

A run-time error results if the GETDATE method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETDECIMAL Method

Returns the designated result set column as type DECIMAL.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETDECIMAL method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETDECIMAL** (*index*);

package.**GETDECIMAL** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type DECIMAL, the column value is converted to type DECIMAL and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETDECIMAL method returns the value of the designated result set column as type DECIMAL. If the designated result set column's type is not type DECIMAL, the column value is converted to type DECIMAL and then returned.

A run-time error results if the GETDECIMAL method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETDOUBLE Method

Returns the designated result set column as type DOUBLE.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETDOUBLE method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETDOUBLE** (*index*);

package.**GETDOUBLE** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type DOUBLE, the column value is converted to type DOUBLE and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETDOUBLE method returns the value of the designated result set column as type DOUBLE. If the designated result set column's type is not type DOUBLE, the column value is converted to type DOUBLE and then returned.

A run-time error results if the GETDOUBLE method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETINTEGER Method

Gets the designated result set column as type INTEGER.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETINTEGER method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETINTEGER** (*index*);

package.**GETINTEGER** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type INTEGER, the column value is converted to type INTEGER and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETINTEGER method returns the value of the designated result set column as type INTEGER. If the designated result set column's type is not type INTEGER, the column value is converted to type INTEGER and then returned.

A run-time error results if the GETINTEGER method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETNCHAR Method

Gets the designated result set column as type NCHAR.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the *rc* status indicator.

Syntax

variable=*package*.**GETNCHAR** (*index*);

package.**GETNCHAR** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type NCHAR, the column value is converted to type NCHAR and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1 (ERROR) an error occurred during data retrieval.

2 (NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETNCHAR method returns the value of the designated result set column as type NCHAR. If the designated result set column's type is not type NCHAR, the column value is converted to type NCHAR and then returned.

A run-time error results if the GETNCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

GETNUMERIC Method

Returns the designated result set column as type NUMERIC.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETNUMERIC method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETNUMERIC** (*index*);

package.**GETNUMERIC** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type NUMERIC, the column value is converted to type NUMERIC and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETNUMERIC method returns the value of the designated result set column as type NUMERIC. If the designated result set column's type is not type NUMERIC, the column value is converted to type NUMERIC and then returned.

A run-time error results if the GETNUMERIC method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

Methods:

- "SETNUMERIC Method" on page 2049

GETNVARCHAR Method

Returns the designated result set column as type NVARCHAR.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETVARCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the *rc* status indicator.

Syntax

variable=*package*.**GETNVARCHAR** (*index*);

package.**GETNVARCHAR** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type NVARCHAR, the column value is converted to type NVARCHAR and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETNVARCHAR method returns the value of the designated result set column as type NVARCHAR. If the designated result set column's type is not type NVARCHAR, the column value is converted to type NVARCHAR and then returned.

A run-time error results if the GETNVARCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETREAL Method

Returns the designated result set column as type REAL.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETREAL method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETREAL** (*index*);

package.**GETREAL** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type REAL, the column value is converted to type REAL and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETREAL method returns the value of the designated result set column as type REAL. If the designated result set column's type is not type REAL, the column value is converted to type REAL and then returned.

A run-time error results if the GETREAL method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

GETSMALLINT Method

Returns the designated result set column as type SMALLINT.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETSMALLINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETSMALLINT** (*index*);

package.**GETSMALLINT** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type SMALLINT, the column value is converted to type SMALLINT and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETSMALLINT method returns the value of the designated result set column as type SMALLINT. If the designated result set column's type is not type SMALLINT, the column value is converted to type SMALLINT and then returned.

A run-time error results if the GETSMALLINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

Methods:

GETTIME Method

Returns the designated result set column as type TIME.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETTIME method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETTIME** (*index*);

package.**GETTIME** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type TIME, the column value is converted to type TIME and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1 (ERROR) an error occurred during data retrieval.

2 (NODATA) there is no more data to be retrieved.

Details

The GETTIME method returns the value of the designated result set column as type TIME. If the designated result set column's type is not type TIME, the column value is converted to type TIME and then returned.

A run-time error results if the GETTIME method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETTIMESTAMP Method

Returns the designated result set column as type TIMESTAMP.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETTIMESTAMP method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETTIMESTAMP** (*index*);

package.**GETTIMESTAMP** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type TIMESTAMP, the column value is converted to type TIMESTAMP and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETTIMESTAMP method returns the value of the designated result set column as type TIMESTAMP. If the designated result set column's type is not type TIMESTAMP, the column value is converted to type TIMESTAMP and then returned.

A run-time error results if the GETTIMESTAMP method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

GETTINYINT Method

Returns the designated result set column as type TINYINT.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETTINYINT method once to return the result set column data. Subsequent method calls result in a value of 2 (NODATA) for the *rc* status indicator.

Syntax

variable=*package*.**GETTINYINT** (*index*);

package.**GETTINYINT** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type TINYINT, the column value is converted to type TINYINT and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETTINYINT method returns the value of the designated result set column as type TINYINT. If the designated result set column's type is not type TINYINT, the column value is converted to type TINYINT and then returned.

A run-time error results if the GETTINYINT method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

GETVARBINARY Method

Returns the designated result set column as type VARBINARY.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETVARBINARY method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the *rc* status indicator.

Syntax

variable=*package*.**GETVARBINARY** (*index*);

package.**GETVARBINARY** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type VARBINARY, the column value is converted to type VARBINARY and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETVARBINARY method returns the value of the designated result set column as type VARBINARY. If the designated result set column's type is not type VARBINARY, the column value is converted to type VARBINARY and then returned.

A run-time error results if the GETVARBINARY method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

GETVARCHAR Method

Returns the designated result set column as type VARCHAR.

Restriction: This method is not supported on the CAS server.

Note: You can call the GETVARCHAR method repeatedly to return the result set column data. When all data has been retrieved, a value of 2 (NODATA) is returned for the *rc* status indicator.

Syntax

variable=*package*.**GETVARCHAR** (*index*);

package.**GETVARCHAR** (*index*, *variable*, *rc*);

Required Arguments

variable
specifies the variable that will hold the value of the designated result set column.

Note If the designated result set column's type is not type VARCHAR, the column value is converted to type VARCHAR and then returned.

package
specifies an instance of the SQLSTMT package.

index
specifies the result set column index ordered sequentially, starting at 1.

rc
specifies the variable in which to place the return code. The following values are possible:

0
(SUCCESS) the result set column data is retrieved.

1
(ERROR) an error occurred during data retrieval.

2
(NODATA) there is no more data to be retrieved.

Details

The FETCH method returns the next row of data from the result set. If variables are not bound to the result set columns, the fetched data can be returned by the GET*type* methods.

The GETVARCHAR method returns the value of the designated result set column as type VARCHAR. If the designated result set column's type is not type VARCHAR, the column value is converted to type VARCHAR and then returned.

A run-time error results if the GETVARCHAR method is called before the result set is fetched.

The result set must be accessed exclusively with bound variables or exclusively with the GET*type* methods. A run-time error results if variables are bound to result set columns and a GET*type* method is invoked.

For more information, see "Accessing Result Set Data" in *SAS DS2 Programmer's Guide*.

ISPREPARED Method

Returns a value that indicates whether the SQLSTMT package instance is prepared.

Restriction: This method is not supported on the CAS server.

Syntax

package.**ISPREPARED**( );

Required Argument

package
specifies an instance of the SQLSTMT package.

Details

The ISPREPARED method returns a value of 0 (false) if the SQLSTMT package instance is not prepared. A nonzero value (true) is returned if the SQLSTMT package instance is prepared.

See Also

Methods:

- "PREPARE Method" on page 2035

Statements:

- "DECLARE PACKAGE Statement: SQLSTMT Package" on page 1997

NEW Operator: SQLSTMT Package

Constructs an instance of an SQLSTMT package.

Restriction: This operator is not supported on the CAS server.

Notes: Braces in the syntax convention indicate a syntax grouping. The escape character (\ ) before a brace indicates that the brace is required in the syntax. *sql-text* must be enclosed in braces ({ }).

The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

Form 1: *package-variable*=**_NEW_ SQLSTMT** ('*sql-text*' [\[*parameter-variable-list*\]]);

Form 2: *package-variable*=**_NEW_ SQLSTMT** ('*sql-text*' [, *connection-string*]);

Form 3: *package-variable*=**_NEW_ SQLSTMT** ( );

Required Arguments

package-variable
specifies a name that can reference an instance of the SQLSTMT package.

'sql-text'
is a valid FedSQL statement that inserts into, updates, selects from, or deletes rows from a table.

CAUTION
Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used. For more information, see *SAS FedSQL Language Reference*.

Requirement: The FedSQL statement must be enclosed in single quotation marks (').

Notes: The statement can be a string literal, a string value generated from an expression, or a string value that is stored in a variable.

The rules for identifiers for the FedSQL language apply to variables used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL parses the string containing the SQL statement rather than DS2.

Optional Arguments

[*parameter-variable-list*]
specifies variables that are bound to the parameters contained in the FedSQL statement.

Requirements: Variables must be in the form of a variable list that must be enclosed in brackets ([]) or a named variable list.

Parameter values must be specified exclusively with either bound variables or exclusively with the SQLSTMT SET*type* methods.

See: "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*

connection-string
contains the fully specified connection string.

Default: If a connection string is not provided, the SQLSTMT package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.

Note: The connection string can be a string literal, a string value generated from an expression, or a string value that is stored in a variable.

Tip: A connection string defines how to connect to the data. A connection string identifies the query language to be submitted as well as the information required to connect to the data source or sources.

See: This parameter is primarily designed for use with the SAS Federation Server. For more information about creating a fully specified connection string, see the *SAS Federation Server: Administrator's Guide*.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use an SQLSTMT package to create and delete tables, select rows from a table, and access the returned result set. The SQLSTMT package is predefined for DS2 programs.

You can declare an SQLSTMT package by using the DECLARE PACKAGE statement. This associates an SQLSTMT package with an SQLSTMT name.

There are two ways to construct an instance of an SQLSTMT package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package sqlstmt sqlpkg;
sqlpkg = _new_ sqlstmt('update db2.dataset2 set y=? where x=?',[y x]);
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package sqlstmt sqlpkg('update db2.dataset2 set y=? where x=?',[y x]);
```

When an SQLSTMT instance is created with SQL text, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the SQLSTMT package's SET*type* methods. The DECLARE PACKAGE statement binds the variables in the optional variable list to the parameters in the FedSQL statement.

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

Methods:

- "BINDPARAMETERS Method" on page 1984

Statements:

- "DECLARE PACKAGE Statement: SQLSTMT Package" on page 1997

PREPARE Method

Prepares a FedSQL statement.

Restriction: This method is not supported on the CAS server.

Syntax

Form 1: **PREPARE** ('*sql-text*');

Form 2: **PREPARE** ('*sql-text*' , *connection-string*);

Required Arguments

'sql-text'
is a valid FedSQL statement or string variable that contains a FedSQL statement that inserts into, updates, selects from, or deletes rows from a table.

CAUTION

Only FedSQL statements can be used with the SQLSTMT package. DBMS-specific SQL cannot be used. For more information, see *SAS FedSQL Language Reference*.

Requirement The FedSQL statement must be enclosed in single quotation marks (') unless the statement is stored in a string variable.

Notes The statement is a string literal.

The rules for identifiers for the FedSQL language apply to variables that are used in the SQLSTMT package, rather than the DS2 rules for identifiers. This occurs because FedSQL (not DS2) parses the string containing the FedSQL statement.

connection-string
contains the fully specified connection string.

Default If a connection string is not provided, the SQLSTMT package instance uses the connection string that is generated by the HPDS2 procedure or the DS2 procedure by using the attributes of the currently assigned libref.

Note The connection string is a string literal.

Tip A connection string defines how to connect to the data. A connection string identifies the query language to be submitted as well as the information required to connect to the data source or sources.

See This parameter is primarily designed for use with the SAS Federation Server. For more information about creating a fully specified connection string, see *SAS Federation Server: Administrator's Guide*.

Details

The PREPARE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

A run-time error occurs if you call the PREPARE method and the FedSQL statement is already prepared.

See Also

Methods:

- "ISPREPARED Method" on page 2032

Statements:

- "DECLARE PACKAGE Statement: SQLSTMT Package" on page 1997

REGISTEROUTPARAMETER Method

Registers the designated parameter as an output parameter.

Restriction: This method is not supported on the CAS server.

Syntax

REGISTEROUTPARAMETER (*index*)

Required Argument

index
is the parameter index, ordered sequentially starting at 1.

Details

The REGISTEROUTPARAMETER is used to map output parameters in the FedSQL statement to IN_OUT parameters in a DS2 package METHOD statement.

The REGISTEROUTPARAMETER method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

Note: Parameter data must be specified exclusively with bound variables. A run-time error results if an SQLSTMT SET*type* method and the REGISTEROUTPARAMETER method are invoked.

Note: After the FedSQL statement is executed, the values of the statement's output parameters are retrieved and written to the bound variables.

Example

The following example illustrates how the SQLSTMT package can be used to execute a DS2 package METHOD statement. The example also shows how to map output parameters in the FedSQL statement to the IN_OUT parameters in the DS2 package METHOD statement.

```
proc ds2;
package swapper / overwrite=yes;
   method swap(in_out int x, in_out int y);
      dcl int t;
```

```
      t = x;
      x = y;
      y = t;
   end;
endpackage;
run;

data _null_;
   dcl int a b;
   method init();
      dcl package sqlstmt stmt();
      dcl int rc;

      rc = stmt.prepare('call swapper.swap(?, ?)');
      if (rc) then put 'TEST ERROR: prepare';

      rc = stmt.bindparameters([a, b]);
      if (rc) then put 'TEST ERROR: bindParameters';

      rc = stmt.registerOutParameter(1);
      if (rc) then put 'TEST ERROR: registerOutParameter';

      rc = stmt.registerOutParameter(2);
      if (rc) then put 'TEST ERROR: registerOutParameter';

      a = 42;
      b = 101;

      put 'Before executing swapper.swap:' a= b=;
      rc = stmt.execute();
      if (rc) then put 'TEST ERROR: execute';
      put 'After executing swapper.swap:' a= b=;
   end;
enddata;
run;
quit;
```

The following lines are written to the SAS log:

```
Before executing swapper.swap: a=42 b=101
After executing swapper.swap: a=101 b=42
```

See Also

Statements:

- “METHOD Statement” on page 1391

SETBIGINT Method

Sets the designated parameter to the specified value of type BIGINT.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETBIGINT** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type BIGINT, the BIGINT value is converted to the designated parameter's type. For example, if you use `setbigint(1, 3)` to set parameter 1 to BIGINT value 3, and parameter 1 is type CHAR, the BIGINT value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETBIGINT method is invoked.

The SETBIGINT method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETBINARY Method

Sets the designated parameter to the specified value of type BINARY.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETBINARY** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for

the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type BINARY, the BINARY value is converted to the designated parameter's type. For example, if you use `setbinary(1, 0110)` to set parameter 1 to BINARY value 0110, and parameter 1 is type CHAR, the BINARY value 0110 is converted to the CHAR value 0110 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETBINARY method is invoked.

The SETBINARY method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETCHAR Method

Sets the designated parameter to the specified value of type CHAR.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETCHAR** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or an expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type CHAR, the CHAR value is converted to the designated parameter's type. For example, if you use `setchar(1, 3)` to set parameter 1 to CHAR value 3, and parameter 1 is type INTEGER, the CHAR value 3 is converted to the INTEGER value 3 and the INTEGER value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETCHAR method is invoked.

The SETCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

- "SETNVARCHAR Method" on page 2050
- "SETVARCHAR Method" on page 2059

SETDATE Method

Sets the designated parameter to the specified value of type DATE.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETDATE** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type DATE, the DATE value is converted to the designated parameter's type.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETDATE method is invoked.

The SETDATE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

- "GETTIME Method" on page 2024
- "GETTIMESTAMP Method" on page 2025
- "SETTIME Method" on page 2054
- "SETTIMESTAMP Method" on page 2055

SETDECIMAL Method

Sets the designated parameter to the specified value of type DECIMAL.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETDECIMAL** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type DECIMAL, the DECIMAL value is converted to the designated parameter's type. For example, if you use `setdecimal(1, 13.4)` to set parameter 1 to DECIMAL value 13.4, and parameter 1 is type CHAR, the DECIMAL value 13.4 is converted to the CHAR value 13.4 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETDECIMAL method is invoked.

The SETDECIMAL method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

Methods:

- "GETDECIMAL Method" on page 2011

SETDOUBLE Method

Sets the designated parameter to the specified value of type DOUBLE.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETDOUBLE** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type DOUBLE, the DOUBLE value is converted to the designated parameter's type. For example, if you use `setdouble(1, 33443452)` to set parameter 1 to DOUBLE value 33443452, and parameter 1 is type CHAR, the DOUBLE value 33443452 is converted to the CHAR value 33443452 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETDOUBLE method is invoked.

The SETDOUBLE method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

Methods:

- "GETDOUBLE Method" on page 2013

SETINTEGER Method

Sets the designated parameter to the specified value of type INTEGER.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETINTEGER** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type INTEGER, the INTEGER value is converted to the designated parameter's type. For example, if you use `setinteger(1, 3)` to set parameter 1 to INTEGER value 3, and parameter 1 is type CHAR, the INTEGER value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETINTEGER method is invoked.

The SETINTEGER method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETNCHAR Method

Sets the designated parameter to the specified value of type NCHAR.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETNCHAR** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type NCHAR, the NCHAR value is converted to the designated parameter's type. For example, if you use `setnchar(1, 3)` to set parameter 1 to NCHAR value 3, and parameter 1 is type INTEGER, the NCHAR value 3 is converted to the INTEGER value 3 and the INTEGER value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETNCHAR method is invoked.

The SETNCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETNUMERIC Method

Sets the designated parameter to the specified value of type NUMERIC.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETNUMERIC** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for

the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type NUMERIC, the NUMERIC value is converted to the designated parameter's type. For example, if you use `setnumeric(1, 3)` to set parameter 1 to NUMERIC value 3, and parameter 1 is type CHAR, the NUMERIC value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETNUMERIC method is invoked.

The SETNUMERIC method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

Methods:

- "GETNUMERIC Method" on page 2017

SETNVARCHAR Method

Sets the designated parameter to the specified value of type NVARCHAR.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETNVARCHAR** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type NVARCHAR, the NVARCHAR value is converted to the designated parameter's type. For example, if you use `setnvarchar(1, 3)` to set parameter 1 to NVARCHAR value 3, and parameter 1 is type INTEGER, the NVARCHAR value 3 is converted to the INTEGER value 3 and the INTEGER value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETNVARCHAR method is invoked.

The SETNVARCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETREAL Method

Sets the designated parameter to the specified value of type REAL.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETREAL** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type REAL, the REAL value is converted to the designated parameter's type. For example, if you use `setreal(1, 3)` to set parameter 1 to REAL value 3, and parameter 1 is type CHAR, the REAL value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETREAL method is invoked.

The SETREAL method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

Methods:

- "GETREAL Method" on page 2021

SETSMALLINT Method

Sets the designated parameter to the specified value of type SMALLINT.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETSMALLINT** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type SMALLINT, the SMALLINT value is converted to the designated parameter's type. For example, if you use `setsmallint(1, 3)` to set parameter 1 to SMALLINT value 3, and parameter 1 is type CHAR, the SMALLINT value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETSMALLINT method is invoked.

The SETSMALLINT method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETTIME Method

Sets the designated parameter to the specified value of type TIME.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETTIME** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type TIME, the TIME value is converted to the designated parameter's type.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETTIME method is invoked.

The SETTIME method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETTIMESTAMP Method

Sets the designated parameter to the specified value of type TIMESTAMP.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETTIMESTAMP** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type TIMESTAMP, the TIMESTAMP value is converted to the designated parameter's type.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETTIMESTAMP method is invoked.

The SETTIMESTAMP method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

■ "SETTIME Method" on page 2054

SETTINYINT Method

Sets the designated parameter to the specified value of type TINYINT.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETTINYINT** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type TINYINT, the TINYINT value is converted to the designated parameter's type. For example, if you use `settinyint(1, 3)` to set parameter 1 to TINYINT value 3, and parameter 1 is type CHAR, the TINYINT value 3 is converted to the CHAR value 3 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETTINYINT method is invoked.

The SETTINYINT method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

- "SETSMALLINT Method" on page 2053

SETVARBINARY Method

Sets the designated parameter to the specified value of type VARBINARY.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETVARBINARY** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type VARBINARY, the VARBINARY value is converted to the designated parameter's type. For example, if you use `setvarbinary(1, 0110)` to set parameter 1 to VARBINARY value 0110, and parameter 1 is type CHAR, the VARBINARY value 0110 is converted to the CHAR value 0110 and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETVARBINARY method is invoked.

The SETVARBINARY method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

For more information, see "Specifying FedSQL Statement Parameter Values" in *SAS DS2 Programmer's Guide*.

SETVARCHAR Method

Sets the designated parameter to the specified value of type VARCHAR.

Restriction: This method is not supported on the CAS server.

Syntax

package.**SETVARCHAR** (*index*, *value*);

Required Arguments

package
specifies an instance of the SQLSTMT package.

index
specifies the parameter index ordered sequentially, starting at 1.

value
specifies the value to which to set the designated parameter. The designated parameter is specified by *index*.

Tip *value* can be a literal, variable, or expression.

Details

When an SQLSTMT instance is created, the FedSQL statement is allocated and prepared. If the FedSQL statement contains parameters, values to substitute for the parameters must be obtained to execute the FedSQL statement. The substitution values can be specified with either the current values of bound variables or with the package's SET*type* methods.

If the designated parameter's type is not type VARCHAR, the VARCHAR value is converted to the designated parameter's type. For example, if you use `setvarchar(1, pass)` to set parameter 1 to VARCHAR value **`pass`**, and parameter 1 is type CHAR, the VARCHAR value **`pass`** is converted to the CHAR value **`pass`** and the CHAR value is used to set the parameter.

Parameter data must be specified exclusively with bound variables or exclusively with the SET*type* methods. A run-time error results if variables are bound to parameters and the SETVARCHAR method is invoked.

The SETVARCHAR method returns a status indicator. Zero is returned for successful execution; 1 is returned if there is an error.

DS2 TZ Package Methods, Operators, and Statements

Dictionary

DECLARE PACKAGE Statement: TZ Package

Creates a package variable and enables you to create an instance of the TZ package.

Category: Local

Syntax

DECLARE PACKAGE TZ *variable* ([*time-zone-id*]);

Required Argument

variable
specifies a name that can reference an instance of the TZ package.

Optional Argument

time-zone-id
specifies a time zone ID.

Default The value specified in the TIMEZONE= system option.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You use a TZ package for time zone processing. The TZ package is predefined for DS2 programs. For more information about time zones in SAS , see *SAS National Language Support (NLS): Reference Guide*.

You declare a TZ package by using the DECLARE PACKAGE statement. This associates a TZ package with a time zone name. After you declare the new TZ package, you can format your date and time data accordingly.

When a package is declared, a variable is created that can reference an instance of the package. If constructor arguments are provided with the package variable declaration, then a package instance is constructed and the package variable is set to reference the constructed package instance. Multiple package variables can be created and multiple package instances can be constructed with a single DECLARE PACKAGE statement, and each package instance represents a completely separate copy of the package.

There are two ways to construct an instance of a TZ package.

- Use the DECLARE PACKAGE statement along with the_NEW_ operator:

```
declare package tz tzpkg;
tzpkg = _new_ tz();
```

- Use the DECLARE PACKAGE statement along with its constructor syntax:

```
declare package tz tzpkg();
```

See Also

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*

- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Operators:

- "_NEW_ Operator: TZ Package" on page 2073

System Options:

- "TIMEZONE= System Option" in *SAS System Options: Reference*

GETLOCALTIME Method

Returns current local time.

Syntax

variable=*package*.**GETLOCALTIME** ([*time-zone-ID*]);

Required Arguments

variable
specifies the variable that will hold the value of the time zone ID of required local time.

package
specifies an instance of the TZ package.

Optional Argument

time-zone-ID
specifies the time zone ID of the required local time.

Example

The following example uses multiple time zones.

```
data _null_ ;
   method init();
      dcl package tz tokyo('Asia/Tokyo')
         london('Europe/London')
         new_york('America/New_York') ;
      dcl double tokyo_time london_time new_york_time utc_time ;
      dcl integer tokyo_off london_off new_york_off ;

      tokyo_time = tokyo.getLocalTime();
      tokyo_off = tokyo.getOffset();
      london_time = london.getLocalTime() ;
```

```
      london_off = london.getOffset() ;
      new_york_time = new_york.getLocalTime() ;
      new_york_off = new_york.getOffset();

      utc_time = tokyo.getUTCTime(); /* can use any timezone */

      put utc_time = datetime. ;
      put tokyo_time = datetime. tokyo_off time5.;
      put london_time = datetime. london_off time5. ;
      put new_york_time = datetime. new_york_off time5. ;

   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
utc_time=08APR15:12:48:41
tokyo_time=08APR15:21:48:41  9:00
london_time=08APR15:13:48:41  1:00
new_york_time=08APR15:08:48:41 -4:00
```

Methods:

- "GETUTCTIME Method" on page 2072

GETOFFSET Method

Returns the time zone offset of the time zone from Universal Coordinated Time (UTC) at the specified local time. If local time is not specified, current local time is used.

Syntax

Form 1: *variable*=*package*.**GETOFFSET** ( );

Form 2: *variable*=*package*.**GETOFFSET** (*local-time*);

Form 3: *variable*=*package*.**GETOFFSET** (*time-zone-ID*);

Form 4: *variable*=*package*.**GETOFFSET** (*local-time*, *time-zone-ID*);

Required Arguments

variable
specifies the variable that will hold the value of the time zone offset.

package
specifies an instance of the TZ package.

local-time
specifies the local time used to get the time zone offset.

Default If local time is not specified, the current local time is used.

Tip *localTime* is a SAS date time value. It is used as the number of seconds since January 1, 1960 00:00:00 local time.

time-zone-ID
specifies the time zone ID of the required time zone offset.

See "Time Zone IDs and Time Zone Names" in *SAS National Language Support (NLS): Reference Guide*

Details

UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form *yyyymmdd*T*hhmmss*+|–*hhmm* or the ISO 8601 extended form *yyyy-mm-dd*T*hh*:*mm*:*ss*+|–*hh*:*mm*.

The time zone offset specifies the number of hours and minutes that a time zone is off from the UTC in the form +|–*hhmm* or +|–*hh*:*mm*

Example

The following example returns the offset from the 'Asia/Tokyo' time zone to the 'America/New_York' time zone. The example also illustrates the different ways in which the time zone ID can be expressed.

```
data _null_;
   method init();

      declare package tz tzone('asia/tokyo');
      dcl double new_york;
      dcl char(40) cstr;

      new_york = tzone.getOffset('America/New_York');
      put new_york time.;

      new_york = tzone.getOffset(n'America/New_York');
      put new_york time.;

      cstr = 'America/New_York';
```

```
      new_york = tzone.getOffset(cstr);
      put new_york time.;

   end;
 enddata;
run;
```

The following lines are written to the SAS log.

```
-4:00:00
-4:00:00
-4:00:00
```

Methods:

- "GETOFFSETUTC Method" on page 2068

GETOFFSETUTC Method

Returns the time zone offset of the time zone from UTC at the specified UTC time.

Syntax

variable=*package*.**GETOFFSETUTC** (*UTC-time*, *time-zone-ID*);

Without Arguments

If no arguments are specified, the GETOFFSETUTC method returns the time zone offset for the specified TIMEZONE= system option.

Required Arguments

variable
specifies the variable that will hold the value of the time zone offset.

package
specifies an instance of the TZ package.

UTC-time
specifies the UTC time used to get the time zone offset.

Tip *UTC-time* is a SAS datetime value at UTC. It is stored as the number of seconds since January 1, 1960 00:00:00 at UTC.

time-zone-ID
specifies the time zone ID of the required time zone offset.

See "Time Zone IDs and Time Zone Names" in *SAS National Language Support (NLS): Reference Guide*

Details

UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form *yyyymmdd*T*hhmmss*+|–*hhmm* or the ISO 8601 extended form *yyyy-mm-dd*T*hh*:*mm*:*ss*+|–*hh*:*mm*.

The time zone offset specifies the number of hours and minutes that a time zone is off from the UTC in the form +|–*hhmm* or +|–*hh*:*mm*

See Also

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETOFFSET Method" on page 2066

GETTIMEZONEID Method

Returns the current time zone ID.

Syntax

variable=*package*.**GETTIMEZONEID** ( );

Required Arguments

package
specifies an instance of the TZ package.

variable
specifies the variable that will hold the value of the time zone ID of the TZ package instance.

Details

The time zone ID specifies a region or area value that is defined by SAS. For more information about time zone IDs, see *SAS National Language Support (NLS): Reference Guide*.

Example

The following example uses the TZ package to calculate time durations.

```
options timezone='asia/tokyo';  /* TIMEZONE ID of origin */

data _null_;
   method route(package tz origin,
      package tz dest,
      timestamp departure,
      time duration);

      dcl nvarchar(50) tzid dest_tzid;
      dcl nvarchar(8)  tzname dest_tzname home_tzn;
      dcl double dept dur arrival utc;
      dcl double home_dept home_arr;

      declare package tz home();

      utc = origin.toUTCTime(departure);
      dur = TO_DOUBLE(duration);
      arrival = dest.toLocalTime(utc+dur);
      tzid = origin.getTimezoneID();
      tzname = origin.getTimezoneName();
      dest_tzid = dest.getTimezoneID();
      dest_tzname = dest.getTimezoneName();

      home_dept = home.toLocalTime(utc);
      home_arr = home.toLocalTime(utc+dur);
      home_tzn = home.getTimezoneName();

      put 'Time Zone: ' tzid 'to' dest_tzid;
      put 'Departure Time: ' departure datetime.  tzname  '/'
         home_dept datetime. home_tzn;
      put '   Arrial Time: ' arrival datetime.  dest_tzname  '/'
        home_arr datetime. home_tzn;
      put;

   end ;
   method init();

      /* print itinerary */
      declare package tz NRT('Asia/Tokyo');
      declare package tz ORD('America/Chicago');
      declare package tz RDU('America/New_York');
      route(NRT,ORD,timestamp '2014-10-19 10:45:00',time '11:35:00');
      route(ORD,RDU,timestamp '2014-10-19 11:03:00',time '01:56:00');
```

```
      route(RDU,ORD,timestamp '2014-10-25 07:45:00',time '02:02:00');
      route(ORD,NRT,timestamp '2014-10-25 10:50:00',time '12:55:00');

   end;
enddata;
run;
```

The following lines are written to the SAS log.

```
Time Zone:  Asia/Tokyo to America/Chicago
Departure Time:  19OCT14:10:45:00JST / 19OCT14:10:45:00JST
   Arrial Time:  19OCT14:08:20:00CDT / 19OCT14:22:20:00JST

Time Zone:  America/Chicago to America/New_York
Departure Time:  19OCT14:11:03:00CDT / 20OCT14:01:03:00JST
   Arrial Time:  19OCT14:13:59:00EDT / 20OCT14:02:59:00JST

Time Zone:  America/New_York to America/Chicago
Departure Time:  25OCT14:07:45:00EDT / 25OCT14:20:45:00JST
   Arrial Time:  25OCT14:08:47:00CDT / 25OCT14:22:47:00JST

Time Zone:  America/Chicago to Asia/Tokyo
Departure Time:  25OCT14:10:50:00CDT / 26OCT14:00:50:00JST
   Arrial Time:  26OCT14:13:45:00JST / 26OCT14:13:45:00JST
```

- "Time Zone IDs and Time Zone Names" in *SAS National Language Support (NLS): Reference Guide*

Methods:

- "GETTIMEZONENAME Method" on page 2071

GETTIMEZONENAME Method

Returns the current time zone name.

Syntax

variable=*package*.**GETTIMEZONENAME** ( );

Required Arguments

package
specifies an instance of the TZ package.

variable
specifies the variable that will hold the value of the time zone name of the TZ package instance.

Details

The time zone name specifies a region or area value that is defined by SAS. For more information about time zone names, see *SAS National Language Support (NLS): Reference Guide*.

Example

See the example in "GETTIMEZONEID Method" on page 2069.

See Also

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*
- "Time Zone IDs and Time Zone Names" in *SAS National Language Support (NLS): Reference Guide*

Methods:

- "GETTIMEZONEID Method" on page 2069

GETUTCTIME Method

Returns the current UTC time.

Syntax

variable=*package*.**GETUTCTIME** ( );

Required Arguments

variable
specifies the variable that will hold the value of the current UTC time.

package
specifies an instance of the TZ package.

See Also

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*

Methods:

- "GETLOCALTIME Method" on page 2065

NEW Operator: TZ Package

Constructs an instance of a TZ package.

Note: The escape character (\ ) before the bracket indicates that the bracket is required in the syntax.

Syntax

package-variable = **_NEW_ TZ**([*time-zone-id*]);

Required Argument

package-variable
specifies a name that can reference an instance of the package.

Optional Argument

time-zone-id
specifies a time zone ID.

Default The value specified in the TIMEZONE= system option.

Details

A DS2 package is a collection of variables and methods of which particular instances can be constructed and used in other DS2 programs.

You declare a TZ package variable using the DECLARE PACKAGE statement. After you declare a TZ package variable, use the _NEW_ operator to instantiate an instance of the TZ package and assign the new package instance to the TZ package variable.

```
declare package tz localtz;
localtz = _new_ tz( );
```

As an alternative to the two-step process of using the DECLARE PACKAGE and the _NEW_ operator to declare and instantiate a TZ package, you can declare and

instantiate the package in one step by using the DECLARE PACKAGE statement as a constructor method. Here is the same example using only the DECLARE PACKAGE statement.

```
declare package tz localtz( );
```

Note: Package variables are subject to all variable scoping rules. For more information, see "Packages, Scope, and Lifetime" in *SAS DS2 Programmer's Guide*.

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*
- "Package Constructors and Destructors" in *SAS DS2 Programmer's Guide*

Statements:

- "DECLARE PACKAGE Statement: TZ Package" on page 2063

TOISO8601 Method

Converts local time to an ISO8601 string with time zone offset.

Syntax

Form 1: *variable*=*package*.**TOISO8601** (*local-time*);

Form 2: *variable*=*package*.**TOISO8601** (*local-time*, *time-zone-ID*);

Required Arguments

variable
specifies the variable that will hold the value of an ISO8601 string such as '2014-10-10T00:01:02.00+09:00'.

package
specifies an instance of the TZ package.

local-time
specifies the local time to convert. *local-time* can be DOUBLE or TIMESTAMP format.

time-zone-ID
specifies the time zone ID of the required local time. Time zone ID 'UTC' can be used to specify UTC time.

See Also

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*
- "Time Zone IDs and Time Zone Names" in *SAS National Language Support (NLS): Reference Guide*

Methods:

- "TOLOCALTIME Method" on page 2075
- "TOTIMESTAMPZ Method" on page 2076
- "TOUTCTIME Method" on page 2077

TOLOCALTIME Method

Converts UTC time to local time.

Syntax

Form 1: *variable*=*package*.**TOLOCALTIME** (*UTC-time*);

Form 2: *variable*=*package*.**TOLOCALTIME** (*UTC-time*, *time-zone-ID*);

Required Arguments

variable
specifies the variable that will hold the value of the local time that is converted from the specified UTC time.

package
specifies an instance of the TZ package.

UTC-time
specifies the current UTC time in DOUBLE or TIMESTAMP format.

time-zone-ID
specifies the time zone ID of the required local time.

Details

UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form *yyyymmdd*T*hhmmss*+|–*hhmm* or the ISO 8601 extended form *yyyy-mm-dd*T*hh*:*mm*:*ss*+|–*hh*:*mm*.

Example

See the example in "GETTIMEZONEID Method" on page 2069.

See Also

Methods:

- "TOISO8601 Method" on page 2074
- "TOTIMESTAMPZ Method" on page 2076
- "TOUTCTIME Method" on page 2077

TOTIMESTAMPZ Method

Converts local time to a TIMESTAMP string with time zone.

Syntax

variable=*package*.**TOTIMESTAMPZ** (*local-time*[, *time-zone-ID*]);

Required Arguments

variable
specifies the variable that will hold the value of a string such as '2014-10-14 00:01:20 Asia/Tokyo'.

package
specifies an instance of the TZ package.

local-time
specifies the local time to convert. *local-time* can be DOUBLE or TIMESTAMP format.

Optional Argument

time-zone-ID
specifies the time zone ID of the required local time. Time zone ID 'UTC' can be specified to use UTC time.

See Also

- "Using the TZ Package" in *SAS DS2 Programmer's Guide*

Methods:

- "TOISO8601 Method" on page 2074
- "TOLOCALTIME Method" on page 2075
- "TOUTCTIME Method" on page 2077

TOUTCTIME Method

Converts local time to UTC time.

Syntax

Form 1: *variable*=*package*.**TOUTCTIME** (*local-time*);

Form 2: *variable*=*package*.**TOUTCTIME** (*local-time*, *time-zone-ID*);

Required Arguments

variable
specifies the variable that will hold the value of the current UTC time in DOUBLE or TIMESTAMP format.

package
specifies an instance of the TZ package.

local-time
specifies the local time to convert. *local-time* can be DOUBLE or TIMESTAMP format.

time-zone-ID
specifies the time zone ID of the required local time.

Details

UTC specifies the time at the zero meridian, near Greenwich, England. UTC is a datetime value that uses the ISO 8601 basic form *yyyymmdd*T*hhmmss*+|–*hhmm* or the ISO 8601 extended form *yyyy-mm-dd*T*hh*:*mm*:*ss*+|–*hh*:*mm*.

PART 4

Appendixes

Appendix 1

Data Type Reference

Data Types for SAS Data Sets

The following table lists the data type support for a SAS data set.

The BINARY and VARBINARY data types are not supported for data definition.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for SAS Data Sets in *SAS Cloud Analytic Services: User's Guide*.

Table A21.1 *Mapping of FedSQL Data Types to Data Types Used by SAS Data Sets*

Data Type Definition Keyword [1]	SAS Data Set Data Type	Description	Data Type Returned
BIGINT[2]	DOUBLE	A 64-bit double precision, floating-point number. **Note:** There is potential for loss of precision.	DOUBLE
CHAR(*n*)	CHAR(*n*)	A fixed-length character string. **Note:** Cannot contain ANSI SQL null values.	CHAR(*n*)
DATE [3]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATE9 SAS format.	DOUBLE
DECIMAL| NUMERIC(*p*,*s*)[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
DOUBLE[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
FLOAT[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
INTEGER[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE

Data Type Definition Keyword [1]	SAS Data Set Data Type	Description	Data Type Returned
NCHAR(*n*)	CHAR(*n*)	A fixed-length character string. By default, sets the encoding to Unicode UTF-8. [4]	CHAR(*n*)
NVARCHAR(*n*)	CHAR(*n*)	A fixed-length character string. By default, sets the encoding to Unicode UTF-8. [4]	CHAR(*n*)
REAL[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
SMALLINT[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
TIME(*p*)[3]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the TIME8 SAS format.	DOUBLE
TIMESTAMP(*p*)[3]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATETIME19.2 SAS format.	DOUBLE
TINYINT[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
VARCHAR(*n*)	CHAR(*n*)	A fixed-length character string. **Note:** Cannot contain ANSI SQL null values.	CHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 Do not apply date and time SAS formats to a numeric data type. For date and time values, use the DATE, TIME, or TIMESTAMP data types.

3 Because the values are stored as a double precision, floating-point number, you can use the values in arithmetic expressions.

4 UTF-8 is an MBCS encoding. Depending on the operating environment, UTF-8 characters are of varying width, from one to four bytes. The value for *n*, which is the maximum number of multibyte characters to store, is multiplied by the maximum length for the operating environment. Note that when you are transcoding, such as from UTF-8 to Wlatin2, the variable lengths (in bytes) might not be sufficient to hold the values, and the result is character data truncation.

Data Types for SPD Engine Data Sets

The following table lists the data type support for an SPD Engine data set.

The BINARY, DECIMAL, NUMERIC, NCHAR, NVARCHAR, and VARBINARY data types are not supported for data type definition.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for SPD Engine Files in *SAS Cloud Analytic Services: User's Guide*.

Table A21.2 *Mapping of FedSQL Data Types to Data Types Used by SPD Engine Data Sets*

Data Type Definition Keyword	SPD Data Set Data Type	Description	Data Type Returned
BIGINT[1]	DOUBLE	A 64-bit double precision, floating-point number. **Note:** There is potential for loss of precision.	DOUBLE
CHAR(*n*)	CHAR(*n*)	A fixed-length character string. **Note:** Cannot contain ANSI SQL null values.	CHAR(*n*)
DATE [2]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATE9 SAS format.	DOUBLE
DOUBLE[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
FLOAT[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
INTEGER[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
REAL[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
SMALLINT[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
TIME(*p*)[2]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the TIME8 SAS format.	DOUBLE
TIMESTAMP(*p*)[2]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATETIME19.2 SAS format.	DOUBLE
TINYINT[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
VARCHAR(*n*)	CHAR(*n*)	A fixed-length character string. **Note:** Cannot contain ANSI SQL null values.	CHAR(*n*)

1 Do not apply date and time SAS formats to a numeric data type. For date and time values, use DATE, TIME, or TIMESTAMP data types.

2 Because the values are stored as double precision, floating-point numbers, you can use the values in arithmetic expressions.

Data Types for SPD Server Tables

The following table lists the data type support for an SPD Server table.

The BINARY, DECIMAL, NUMERIC, NCHAR, NVARCHAR, and VARBINARY data types are not supported for data type definition.

Note: This data source is not supported on the CAS server.

Table A21.3 *Mapping of FedSQL Data Types to Data Types Used by SPD Server Tables*

Data Type Definition Keyword	SPD Data Set Data Type	Description	Data Type Returned
BIGINT[1]	DOUBLE	A 64-bit double precision, floating-point number. **Note:** There is potential for loss of precision.	DOUBLE
CHAR(*n*)	CHAR(*n*)	A fixed-length character string. **Note:** Cannot contain ANSI SQL null values.	CHAR(*n*)
DATE [2]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATE9 SAS format.	DOUBLE
DOUBLE[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
FLOAT [1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
INTEGER[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE

Data Type Definition Keyword	SPD Data Set Data Type	Description	Data Type Returned
REAL[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
SMALLINT[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
TIME(*p*)[2]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the TIME8 SAS format.	DOUBLE
TIMESTAMP(*p*)[2]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATETIME19.2 SAS format.	DOUBLE
TINYINT[1]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
VARCHAR(*n*)	CHAR(*n*)	A fixed-length character string. **Note:** Cannot contain ANSI SQL null values.	CHAR(*n*)

1 Do not apply date and time SAS formats to a numeric data type. For date and time values, use DATE, TIME, or TIMESTAMP data types.

2 Because the values are stored as double precision, floating-point numbers, you can use the values in arithmetic expressions.

Data Types for CAS

The following table lists the data type support for a CAS table.

The BINARY, DECIMAL/NUMERIC, and REAL data types are not supported.

In order to read or update a CAS table that contains a BINARY column with DS2, you must drop the BINARY column from the table first. DS2 returns an error when it encounters a BINARY column in a CAS table.

Table A21.4 *Mapping of FedSQL Data Types to Data Types Used by CAS Tables*

Data Type Definition Keyword[1]	CAS Data Type	Description	Data Type Returned
BIGINT[2]	INT64	A large signed, exact whole number, with a precision of 19 digits. The range of integers is -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807. Integer data types do not store decimal values; fractional portions are discarded. A DS2 value that corresponds to the most negative possible BIGINT (INT64) value in a BIGINT column in a CAS table is treated as a SAS missing or null value.	BIGINT
CHAR(*n*)	CHAR(*n*)	A fixed-length character string. When a string value is less than *n* in length, the value is blank-padded to *n*. [4] **Note:** ANSI SQL null values in a string are converted to SAS missing values.	CHAR(*n*) [5]
DATE [3]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATE9. SAS format.	DOUBLE
DOUBLE[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
FLOAT[2]	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
INTEGER[2]	INT32	A regular signed, exact whole number, with a precision of 10 digits. The range of integers is -2,147,483,648 to 2,147,483,647. Integer data types do not store decimal values; fractional portions are discarded. A DS2 value that corresponds to the most negative possible INTEGER (INT32) value in an INTEGER column in a CAS table is treated as a SAS missing or null value.	INTEGER
NCHAR(*n*)	CHAR(*n*)	A fixed-length national character string. If a string value is less than *n* in length, the value is blank-padded to *n*. [4] **Note:** ANSI SQL null values in a string are converted to SAS missing values.	CHAR(*n*)

Data Type Definition Keyword[1]	CAS Data Type	Description	Data Type Returned
NVARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string. *n* is the maximum length of the string that can be stored.[6] **Note:** ANSI SQL null values in a string are converted to SAS missing values.	VARCHAR(*n*)
SMALLINT[2]	INT32	A small signed, exact whole number.	INTEGER
TIME(*p*)[3]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the TIME8. SAS format.	DOUBLE
TIMESTAMP(*p*)[3]	DOUBLE	A 64-bit double precision, floating-point number. By default, applies the DATETIME25.6 SAS format.	DOUBLE
TINYINT[2]	INT32	A very small signed, exact whole number.	INTEGER
VARBINARY	VARBINARY	Varying-length binary opaque data. This data type is used to store image data, audio, documents, and other unstructured data.	VARBINARY
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string. *n* is the maximum length of the string that can be stored.[6] **Note:** ANSI SQL null values in a string are converted to SAS missing values.	VARCHAR(*n*)[5]

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 Do not apply date and time SAS formats to a numeric data type. For date and time values, use the DATE, TIME, or TIMESTAMP data types.

3 Because the values are stored as a double precision, floating-point number, you can use the values in arithmetic expressions.

4 For a DS2 CHAR and NCHAR character data types, the value for *n* is the number of characters to store. For CAS CHAR and NCHAR character types, the value for *n* is the number of bytes to store. CAS tables use the UTF-8 character set. UTF-8 is a multibyte character set encoding. UTF-8 characters are of varying width, from 1 to 4 bytes. When a DS2 character value is saved to a CAS character column, the string data is truncated if the value requires more than *n* bytes in its UTF-8 encoded representation. When a DS2 character value is used to read a CAS character column, the string data is truncated if the value requires more than *n* characters in the active session encoding.

5 DS2 character types use the session encoding by default. This data type enables you to specify an alternate character set encoding when defining columns. When the DS2 data type specifies an encoding other than UTF-8 in a DS2 CAS action, the data is transcoded to and from UTF-8 when data is written to or read from CAS.

6 For DS2 and CAS NVARCHAR and VARCHAR data types, the value for *n* is the number of characters to store.

Data Types for Amazon Redshift

The following table lists the data type support for an Amazon Redshift database.

The BINARY, TINYINT, and VARBINARY data types are not supported for data type definition.

For data source-specific information about Redshift data types, see the Amazon Redshift database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Amazon Redshift in *SAS Cloud Analytic Services: User's Guide*.

Table A21.5 *Mapping of FedSQL Data Types to Data Types Used by Amazon Redshift*

Data Type Definition Keyword [1]	Amazon Redshift Data Type	Description	Data Type Returned
BIGINT	BIGINT	A signed eight-byte integer.	BIGINT
[2]	BOOLEAN	A logical Boolean (true/ false) value.	[2]
CHAR(*n*)	CHAR	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	DECIMAL, NUMERIC	A signed, fixed-point decimal number.	DECIMAL| NUMERIC(*p*,*s*)[4]
DOUBLE	DOUBLE PRECISION	A signed, double precision, floating-point number.	DOUBLE
FLOAT	FLOAT	A signed, double precision, floating-point number.	DOUBLE
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER

Data Type Definition Keyword [1]	Amazon Redshift Data Type	Description	Data Type Returned
NCHAR	NCHAR	A fixed-length Unicode character string.	CHAR
NVARCHAR	NVARCHAR	A varying length Unicode character string.	CHAR
REAL	REAL	A signed, single precision floating-point number.	REAL
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
TIME(*p*)	[3]	A time value.	TIMESTAMP
TIMESTAMP(*p*)	TIMESTAMP	A date and time value.	TIMESTAMP(*p*)
[2]	TIMESTAMPZ	A date and time value with time zone.	[2]
VARCHAR(*n*)	VARCHAR	A varying-length character string.	CHAR

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Amazon Redshift data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 Amazon Redshift does not support the TIME(*p*) data type. When you define a column of type TIME, a column of type TIMESTAMP is created instead.

4 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for DB2 under UNIX and PC Hosts

The following table lists the data type support for a DB2 database under UNIX and PC hosts.

The NCHAR, NVARCHAR, and TINYINT data types are not supported for data type definition.

For data source-specific information about the DB2 database data types, see the DB2 database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for DB2 in *SAS Cloud Analytic Services: User's Guide*.

Table A21.6 *Mapping of FedSQL Data Types to Data Types Used by DB2 under UNIX and PC Hosts*

Data Type Definition Keyword[1]	DB2 Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	CHAR(*n*) FOR BIT DATA	A fixed-length binary string.	BINARY(*n*)
[2]	BLOB(*n*[K|M|G])	A binary large object string of varying length.	[2]
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
[2]	CLOB(*n*[K|M|G])	A varying-length character large object string.	[2]
DATE	DATE	A date value.	DATE
[2]	DBCLOB(*n*[K|M|G])	A varying-length, double-byte character large object.	[2]
DECIMAL|NUMERIC(*p*,*s*)	DECIMAL|NUMERIC(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL|NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE	A signed, double precision, floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A signed, double precision, floating-point number.	DOUBLE
[2]	GRAPHIC(*n*)	A fixed-length graphic string.	[2]
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER

Data Type Definition Keyword[1]	DB2 Data Type	Description	Data Type Returned
[2]	LONG VARCHAR [FOR BIT DATA]	A varying-length character or binary string.	[2]
[2]	LONG VARGRAPHIC(*n*)	A varying-length graphic string.	[2]
REAL	REAL	A signed, single precision, floating-point number.	REAL
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
VARBINARY(*n*)	VARCHAR(*n*) FOR BIT DATA	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string.	VARCHAR(*n*)
[2]	VARGRAPHIC(*n*)	A varying-length graphic string.	[2]

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The DB2 data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Google BigQuery

The following table lists the data type support for a Google BigQuery project.

The Google BigQuery ARRAY, STRUCT, and GEOGRAPHY data types are not supported.

For data source-specific information about Google BigQuery data types, see the Google BigQuery documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Google BigQuery in *SAS Cloud Analytic Services: User's Guide*.

Table A21.7 *Mapping of FedSQL Data Types to Data Types Used by Google BigQuery*

Data Type Definition Keyword	BigQuery Data Type	BigQuery Description	Data Type Returned
BIGINT	INT64	A large signed, exact whole number, with a range of -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.	BIGINT
[1]	BIGNUMERIC(*p,s*)	A double precision, floating-point number.	DOUBLE[4, 5]
BINARY	BYTES	A varying-length binary string.	VARBINARY[2]
[1]	BOOL	A Boolean value represented as True or False (case-insensitive).	[1]
CHAR(*n*)	STRING	A varying-length Unicode character string.	VARCHAR[3]
DATE	DATE	A date value from 0001-01-01 to 9999-12-31.	DATE
DOUBLE	FLOAT64	A double precision, floating-point number.	DOUBLE
FLOAT	FLOAT64	A double precision, floating-point number.	DOUBLE
INTEGER	INT64	A regular signed, exact whole number.	BIGINT
NCHAR	STRING	A fixed-length Unicode character string.	VARCHAR
NUMERIC(*p,s*)	NUMERIC(*p,s*)	A double precision, floating-point number.	DOUBLE[4, 5]
NVARCHAR	STRING	A varying-length Unicode character string.	VARCHAR
SMALLINT	INT64	A small signed, exact whole number.	BIGINT

Data Type Definition Keyword	BigQuery Data Type	BigQuery Description	Data Type Returned
TIME(*p*)	TIME	A time value in hours, minutes, and seconds, in the range 00:00:00 to 23:59:59.999999.	TIME(*p*)
[1]	TIMESTAMP	A date and time value.	[1]
TIMESTAMP(*p*)	DATETIME	A date and time value with microsecond precision, independent of any time zone or convention such as Daylight Saving Time. Supported values are 0001-01-01 00:00:00 to 9999-12-31 23:59:59.999999 UTC.	TIMESTAMP(p)
TINYINT	INT64	A very small signed, exact whole number.	BIGINT
VARBINARY(*n*)	BYTES	A varying-length binary string.	VARBINARY [2]
VARCHAR(*n*)	STRING	A varying-length Unicode character string.	VARCHAR[3]

1 The BigQuery data type cannot be defined and when data is retrieved, the native data type is mapped to a similar data type.

2 Length is determined by the MAX_BINARY_LEN= LIBNAME option. If MAX_BINARY_LEN= is not set, the default length is 2,000 bytes.

3 The default length is 16,384 characters unless the MAX_CHAR_LEN= LIBNAME option or SCANSTRINGCOLUMNS table option is set.

4 Starting in 2024.09, Google BigQuery NUMERIC(p,s) and BIGNUMERIC(p,s) columns are treated as DOUBLEs, which map to the BigQuery FLOAT64 type. The FETCH_NUMERIC_TYPE= table option is provided to enable you to request that these types be treated as standard NUMERIC(p,s) types.

5 When FETCH_NUMERIC_TYPE=NUMERIC is set, the NUMERIC(p,s) and BIGNUMERIC(p,s) types are supported in requests that can be fully passed down to the data source. NUMERIC(p,s) and BIGNUMERIC(p,s) columns in requests that cannot be fully passed down to the data source are handled as DOUBLE. For more information, see "What Are the Data Types?" in *SAS DS2 Programmer's Guide*.

Data Types for Greenplum

The following table lists the data type support for a Greenplum database.

The BINARY, NCHAR, NVARCHAR, and TINYINT data types are not supported for data type definition.

For data source-specific information about Greenplum data types, see the Greenplum database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Greenplum in *SAS Cloud Analytic Services: User's Guide*.

Table A21.8 *Mapping of FedSQL Data Types to Data Types Used by Greenplum*

Data Type Definition Keyword[1]	Greenplum Data Type	Description	Data Type Returned
BIGINT	INT8	A large signed, exact whole number.	BIGINT
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
DECIMAL|NUMERIC(*p*,*s*)	DECIMAL(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL|NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE	A floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A floating-point number.	DOUBLE
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER
REAL	REAL	A floating-point number.	REAL
SMALLINT	INT8	A small signed, exact whole number.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value in hours, minutes, and seconds.	TIME(*p*)[2]
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
VARBINARY(*n*)	BYTEA	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 Due to the ODBC-style interface that is used to communicate with the Greenplum server, fractional seconds are lost in the data transfer from server to client.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Hive

The following table lists the data type support for Hive.

The NCHAR and NVARCHAR data types are not available for data definition.

The Hive complex data types can be read, but they are not available for data definition.

For data source-specific information about Hive data types, see the Hive database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Hadoop in *SAS Cloud Analytic Services: User's Guide*.

Table A21.9 *Mapping of FedSQL Data Types to Data Types Used by Hive*

Data Type Definition Keyword	Hive Data Type	Description	Data Type Returned
[1, 4]	ARRAY<*data-type*>	An array of integers (indexable lists).	STRING[8]
BIGINT	BIGINT	A signed eight-byte integer, from -9,223,372,036,854,775,807 to 9,223,372,036,854,775,807.	BIGINT
BINARY(*n*)	BINARY	A varying-length binary string up to 32K.	BINARY
[1]	BOOLEAN	A textual true or false value.	TINYINT
CHAR(*n*)	CHAR(n)	A character string up to 255 characters. If you specify CHAR with a value greater than 255 characters, the column is created as VARCHAR(n) instead.	CHAR
DATE	DATE[2]	An ANSI SQL date type.	DATE
DECIMAL/ NUMERIC(*p*,*s*)	DECIMAL	A fixed-point decimal number, with 38 digits precision.	DECIMAL(*p*,*s*)[3]

Data Type Definition Keyword	Hive Data Type	Description	Data Type Returned
DOUBLE	DOUBLE	An eight-byte, double precision floating-point number.	DOUBLE
FLOAT	FLOAT	An eight-byte, double precision floating-point number.	DOUBLE
INTEGER	INTEGER	A regular size signed, exact whole number, with a precision of 10 digits. The range of integers is -2,147,483,647 to 2,147,483,647.	INTEGER
[1, 4]	MAP<*primitive-type*, *data-type*>	An associative array of key-value pairs.	STRING[8]
REAL	DOUBLE	A A 64-bit double precision, floating-point number.	DOUBLE
SMALLINT	SMALLINT	A signed two-byte integer, from -32,767 to 32,767.	SMALLINT
[1, 4]	STRING	A varying-length character string.	VARCHAR(n)[6]
[1, 4]	STRUCT<*col-name*: *data-type*>	A structure with established column elements and data types. Column elements and data types are mapped using a double-dot (:) notation.	STRING[8]
TIME(*p*)	[7]	A time value.	STRING
TIMESTAMP(*p*)	TIMESTAMP	A UNIX timestamp with optional nanosecond precision.	TIMESTAMP[(*p*)]
TINYINT	TINYINT	A signed one-byte integer, from -127 to 127.	TINYINT
[1, 4]	UNION<*data-type*, *data-type-n*>	A type that can hold one of several specified data types.	STRING[8]
VARCHAR(*n*)[5]	VARCHAR(*n*)	A varying-length character string.	STRING

Data Type Definition Keyword	Hive Data Type	Description	Data Type Returned
VARBINARY	BINARY	A varying-length binary string up to 32K.	BINARY

1 The Hive data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

2 The supported date values are between October 15, 1582 and December 31, 9999. Date values containing years earlier than 1582 return an error. Date values later than 9999 are read back as null values.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

4 String and Hive complex types are loaded as VARCHAR(*n*), whose length is determined by the DBMAX_TEXT= data source connection option.

5 VARCHAR columns with values greater than 65,535 characters are created as STRING.

6 SASFMT TableProperties are applied when reading STRING columns.

7 Hive does not support the TIME(p) data type. When data is read from Hive, STRING columns that have SASFMT TableProperties defined that specify the SAS TIME8. format are converted to the TIME(*p*) data type. When the TIME type is used for data definition, it is mapped to a STRING column with SASFMT TableProperties. Fractional seconds are not preserved. For more information about SASFMT TableProperties, see "SAS Table Properties for Hive and HADOOP" in *SAS/ACCESS for Relational Databases: Reference*.

8 The complex types ARRAY, MAP, STRUCT, and UNION are read as their STRING representation of the underlying complex type. ARRAY values are read back within brackets, for example: [1, 2, 4]. STRUCT and MAP values are read back within braces, for example: {"firstname":"robert","nickname":"bob"}.

Data Types for Impala

The following table lists the data type support for Impala.

The BINARY, DECIMAL(*p.s*)/NUMERIC, NCHAR, NVARCHAR, and VARBINARY data types are not available for data definition.

For data source-specific information about Impala data types, see the vendor documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Impala in *SAS Cloud Analytic Services: User's Guide*.

Table A21.10 *Mapping of FedSQL Data Types to Data Types Used by Impala*

Data Type Definition Keyword	Impala Data Type	Description	Data Type Returned
BIGINT	BIGINT	A signed eight-byte integer, from	BIGINT

Data Type Definition Keyword	Impala Data Type	Description	Data Type Returned
		-9,223,372,036,854,775,807 to 9,223,372,036,854,775,807.	
CHAR(*n*)	CHAR[1]	A fixed-length character string up to 255 characters.	CHAR
DATE	[2]	An ANSI SQL date type.	TIMESTAMP
DOUBLE	DOUBLE	An eight-byte, double precision floating-point number.	DOUBLE
FLOAT	FLOAT	An eight-byte, double precision floating-point number.	DOUBLE
INTEGER	INT	A signed four-byte integer, from -2,147,483,647 to 2,147,483,647.	INTEGER
REAL	DOUBLE	An eight-byte, double precision floating-point number.	DOUBLE
SMALLINT	SMALLINT	A signed two-byte integer, from -32,767 to 32,767.	SMALLINT
TIME	[2]	A time value.	TIMESTAMP
TIMESTAMP	TIMESTAMP	A UNIX timestamp with optional nanosecond precision.	TIMESTAMP
TINYINT	TINYINT	A signed one-byte integer, from -127 to 127.	TINYINT
VARCHAR(*n*)	VARCHAR[1]	A varying-length character string.	VARCHAR

1 Support for this data type is available in CDH 5.2 and later. In environments that use earlier CDH versions, which do not support the CHAR and VARCHAR types, columns defined as CHAR or VARCHAR are mapped to STRING.

2 Impala does not support this data type. When a DATE or TIME column is defined, it is created as a column of type TIMESTAMP.

Data Types for JDBC

The following table lists the data type support for JDBC.

For data source-specific information about JDBC data types, see the database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for JDBC in *SAS Cloud Analytic Services: User's Guide*.

Table A21.11 *Mapping of FedSQL Data Types to Data Types Supported by JDBC*

Data Type Definition Keyword	JDBC SQL Identifier	Description	Data Type Returned
BIGINT	SQL_BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	SQL_BINARY	A fixed-length binary string.	BINARY(*n*)
[1]	SQL_BIT	A single-bit binary value.	[1]
CHAR(*n*)[2]	SQL_CHAR	A fixed-length character string.	CHAR(*n*)
DATE	SQL_TYPE_DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	SQL_DECIMAL| SQL_NUMERIC	A signed, fixed-point decimal number.	DECIMAL| NUMERIC(*p*,*s*)[3]
DOUBLE	SQL_DOUBLE	A signed, double precision, floating-point number.	DOUBLE
FLOAT	SQL_FLOAT	A signed, double precision, floating-point number.	DOUBLE
[1]	SQL_GUID	A globally unique identifier.	[1]

Data Type Definition Keyword	JDBC SQL Identifier	Description	Data Type Returned
INTEGER	SQL_INTEGER	A regular signed, exact whole number.	INTEGER
[1]	SQL_INTERVAL	An interval between two years, months, days, dates or times.	[1]
[1]	SQL_LONGVARBINARY	A varying-length binary string.	[1]
[1]	SQL_LONGVARCHAR	A varying-length Unicode character string.	[1]
NCHAR(*n*)	SQL_WCHAR	A fixed-length Unicode character string.	NCHAR(*n*)
NVARCHAR(*n*)	SQL_WVARCHAR	A varying-length Unicode character string.	NVARCHAR(*n*)
REAL	SQL_REAL	A signed, single precision, floating-point number.	REAL
SMALLINT	SQL_SMALLINT	A small signed, exact whole number.	SMALLINT
TIME(*p*)	SQL_TYPE_TIME	A time value.	TIME(*p*)
TIMESTAMP(*p*)	SQL_TYPE_TIMESTAMP	A date and time value.	TIMESTAMP(*p*)
TINYINT	SQL_TINYINT	A very small signed, exact whole number.	TINYINT
VARBINARY(*n*)	SQL_VARBINARY	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)[2]	SQL_VARCHAR	A varying-length character string.	VARCHAR(*n*)

Data Type Definition Keyword	JDBC SQL Identifier	Description	Data Type Returned
[1]	SQL_WLONGVARCHAR	A varying-length Unicode character string.	[1]

1 The JDBC SQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.
2 When you use the CHAR(n) or VARCHAR(n) data type to store multibyte data, you must specify the encoding in the CLIENT_ENCODING= connection option. Or, to avoid having to set the encoding, use the NCHAR or NVARCHAR data types for multibyte data instead.
3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for MDS

The following table lists the data type support for the in-memory database.

Note: This data source is not supported on the CAS server.

Table A21.12 *Mapping of FedSQL Data Types to Data Types Used by MDS Tables*

Data Type Definition Keyword [2]	MDS Data Type	Description	Data Type Returned
BIGINT	BIGINT	A 64-bit, signed integer.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY(*n*)
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	NUMERIC(*p*,*s*)	An exact whole number with fixed precision and scale.	DECIMAL/ NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE	An eight-byte IEEE floating-point value. **Note:** Supports ANSI SQL null values.	DOUBLE

Data Type Definition Keyword [2]	MDS Data Type	Description	Data Type Returned
FLOAT	DOUBLE	An eight-byte IEEE floating-point value. **Note:** Supports ANSI SQL null values.	DOUBLE
INTEGER	INTEGER	A 32-bit, signed integer.	INTEGER
NCHAR(*n*)	NCHAR(*n*)	A fixed-length Unicode character string.	NCHAR(*n*)
NVARCHAR(*n*)	NVARCHAR(*n*)	A varying-length Unicode character string.	NVARCHAR(*n*)
REAL	DOUBLE	An eight-byte IEEE floating-point value. **Note:** Supports ANSI SQL null values.	DOUBLE
SMALLINT	INTEGER	A 32-bit, signed integer.	INTEGER
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
TINYINT	INTEGER	A 32-bit, signed integer.	INTEGER
[1]	UBIGINT	A 64-bit, unsigned integer.	BIGINT
[1]	UINTEGER	A 32-bit, unsigned integer.	INTEGER
VARCHAR(*n*)	VARCHAR(n)	A varying-length character string.	VARCHAR(*n*)
VARBINARY(n)	VARBINARY(n)	A varying-length binary string.	VARBINARY(n)

1 The MDS SQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

2 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Microsoft SQL Server

The following table lists the data type support for a Microsoft SQL Server database.

For data source-specific information about the Microsoft SQL Server data types, see the Microsoft SQL Server database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Microsoft SQL Server in *SAS Cloud Analytic Services: User's Guide*.

Table A21.13 *Mapping of FedSQL Data Types to Data Types Used by Microsoft SQL Server*

Data Type Definition Keyword[1]	SQL Server SQL Identifier	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY(*n*)
[2]	BIT	A single-bit binary value.	[2]
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
[2]	DATETIME	A date and time value with fractional seconds that is based on a 24-hour clock.	TIMESTAMP(*p*)
[2]	DATETIME2(*p*)	An extended DATETIME value with a larger date range, a larger default fractional precision, and optional user-specified precision.	TIMESTAMP(*p*)

Data Type Definition Keyword[1]	SQL Server SQL Identifier	Description	Data Type Returned
[2]	DATETIMEOFFSET(*p*)	A date and time value with time zone awareness.	[2]
DECIMAL| NUMERIC(*p*,*s*)	DECIMAL| NUMERIC(*p*,*s*)	A signed, number with fixed-precision and scale.	DECIMAL| NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE	A signed, double precision, floating-point number.	DOUBLE
FLOAT	FLOAT	A signed, double precision, floating-point number.	DOUBLE
[2]	IMAGE	A varying-length binary value.	[2]
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER
[2]	MONEY	An eight-byte currency value.	DECIMAL(19,4)[3]
NCHAR(*n*)	NCHAR	A fixed-length Unicode character string.	NCHAR(*n*)
NVARCHAR(*n*)	NVARCHAR	A varying-length Unicode character string.	NVARCHAR(*n*)
REAL	REAL	A signed, single precision, floating-point number.	REAL
[2]	SMALLDATETIME	A date and time value without fractional seconds.	TIMESTAMP(*p*)
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
[2]	SMALLMONEY	A four-byte currency value.	DECIMAL(10,4)[3]

Data Type Definition Keyword[1]	SQL Server SQL Identifier	Description	Data Type Returned
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	BINARY(8)	A date and time value.	TIMESTAMP(*p*)
TINYINT	TINYINT	A very small signed, exact whole number.	TINYINT
[2]	UNIQUEIDENTIFIER	A globally unique identifier.	CHAR(36)
VARBINARY(*n*)	VARBINARY	A varying-length binary string.	VARBINARY(*n*)
[2]	VARBINARY(MAX)	A varying-length binary string. Maximum 2GB.	[2]
VARCHAR(*n*)	VARCHAR(*n*), TEXT	A varying-length character string.[2]	VARCHAR(*n*)
[2]	VARCHAR(MAX)	A varying-length Unicode character string. Maximum 2GB.	[2]

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Microsoft SQL Server data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for MongoDB

The following table lists the data type support for a MongoDB non-relational database.

The MongoDB types Timestamp, Min key, and Max key are internal to MongoDB. Therefore, they are not read by SAS.

The FedSQL BINARY, DECIMAL, FLOAT, NCHAR, NVARCHAR, REAL, SMALLINT, TINYINT, and VARBINARY data types are not supported for data definition.

For data source-specific information about MongoDB data types, see the MongoDB documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for MongoDB in *SAS Cloud Analytic Services: User's Guide*.

Table A21.14 *Mapping of FedSQL Data Types to Data Types Used by MongoDB*

Data Type Definition Keyword	MongoDB Data Type	Description	Data Type Returned
[1]	Array	An array.	VARCHAR(n)
BIGINT	int	A regular 64-bit exact whole number.	BIGINT
[2]	BinData	A binary value.	VARCHAR[3]
[2]	Bool	A Boolean value.	INTEGER
CHAR(*n*)	String	A fixed-length UTF-8 character string.	CHAR(*n*)
DATE	Date	A date and time value.	DATE
[2]	Decimal	A Decimal128 value.	DOUBLE
DOUBLE	Double	A signed double precision, floating-point number.	DOUBLE
INTEGER	Int	A regular 32-bit exact whole number.	INTEGER
[2]	Javascript	A Javascript string.	[1]
[2]	Long	A large signed, exact whole number.	BIGINT
[2]	Null	A null value.	VARCHAR
[1]	Object	A JSON object.	VARCHAR(n)
[2]	ObjectId[4]	An object identifier.	VARCHAR
[2]	Regex	A regular expression string.	VARCHAR
TIME	Date	A time value.	TIME
TIMESTAMP	Date	A date and time value.	TIMESTAMP

Data Type Definition Keyword	MongoDB Data Type	Description	Data Type Returned
VARCHAR	String	A varying-length UTF-8 character string.	VARCHAR, CHAR(*n*)[5]

1 The array and object types are modeled as separate child tables. For more information, see the documentation for MongoDB in *SAS/ACCESS for Nonrelational Databases: Reference*. The Javascript type is mapped to VARCHAR.

2 The MongoDB data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 Contains a hexadecimal string representation of binary data.

4 You cannot define or duplicate an ObjectId field in a MongoDB table. However, you can insert and update values in ObjectId fields that already exist in a MongoDB collection.

5 You can customize the default MongoDB schema to use CHAR(n). For more information, see the documentation for MongoDB in *SAS/ACCESS for Nonrelational Databases: Reference*.

Data Types for MySQL

The following table lists the data type support for a MySQL database.

The NCHAR, NVARCHAR, REAL, and VARBINARY data types are not supported for data type definition.

For data source-specific information about MySQL data types, see the MySQL database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for MySQL in *SAS Cloud Analytic Services: User's Guide*.

Table A21.15 *Mapping of FedSQL Data Types to Data Types Used by MySQL*

Data Type Definition Keyword[1]	MySQL Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY(*n*)
[2]	BLOB	A binary large object string.	[2]
CHAR(*n*)	CHAR(*n*)[3]	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE

Data Type Definition Keyword[1]	MySQL Data Type	Description	Data Type Returned
[2]	DATETIME	A date and time value.	[2]
DECIMAL| NUMERIC(*p*,*s*)	DECIMAL(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL(*p*,*s*)[4]
DOUBLE	DOUBLE	A signed, double precision, floating-point number.	DOUBLE
[2]	ENUM(*values*)	A character value from a list of allowed values.	[2]
FLOAT	FLOAT(*p*)	A signed, double precision, floating-point number.	DOUBLE
INTEGER	INT	A regular signed, exact whole number.	INTEGER
[2]	JSON	A varying-length character string in JSON format.	VARCHAR
[2]	LONGBLOB	A binary large object string of varying length.	[2]
[2]	LONGTEXT	A text string of varying length.	[2]
[2]	MEDIUMBLOB	A binary large object string of varying length.	[2]
[2]	MEDIUMINT	A regular signed, exact whole number.	[2]
[2]	MEDIUMTEXT	A varying-length character string.	[2]
[2]	SET(*values*)	A character value from a list of allowed values.	[2]
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
[2]	TEXT	A text string.	[2]
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	DATETIME(*p*)	A date and time value.	TIMESTAMP(*p*)
[2]	TINYBLOB	A binary large object string of varying length.	[2]

Data Type Definition Keyword[1]	MySQL Data Type	Description	Data Type Returned
TINYINT	TINYINT	A very small signed, exact whole number.	TINYINT
[2]	TINYTEXT	A text string of varying length.	[2]
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The MySQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 DS2 uses ANSI SQL rules for handling blank spaces in fixed character values. MySQL 8 treats trailing blank spaces as significant values by default. This difference interferes with character comparisons that are performed when using FedSQL statements in DS2. When using DS2 to issue FedSQL statements on MySQL 8 CHAR() data, it is necessary to use the TRIM function in the FedSQL statement to ensure that the data is read correctly. For information about the locations in which FedSQL statements are supported in DS2, see "Using DS2 and FedSQL" in *SAS DS2 Programmer's Guide*.Also see: "Example: Filter Trailing Spaces from MySQL 8 CHAR() Data" on page 2229. MySQL 8 uses utf8mb4_0900_ai_ci as the default collation for comparisons.

4 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Netezza

The following table lists the data type support for a Netezza database.

The BINARY and VARBINARY data types are not supported for data type definition.

For data source-specific information about Netezza data types, see the Netezza database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Netezza in *SAS Cloud Analytic Services: User's Guide*.

Table A21.16 *Mapping of FedSQL Data Types to Data Types Used by Netezza*

Data Type Definition Keyword[1]	Netezza Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number.	BIGINT

Data Type Definition Keyword[1]	Netezza Data Type	Description	Data Type Returned
CHAR(*n*)	CHAR(*n*)	A fixed-length character string data.	CHAR(*n*)
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	DECIMAL(*p*,*s*)	A fixed-point decimal number.	DECIMAL(*p*,*s*)[3]
DOUBLE	DOUBLE	A floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A 64-bit double precision, floating-point number.	DOUBLE
INTEGER	INTEGER	A large integer.	INTEGER
NCHAR(*n*)	NCHAR(*n*)	A fixed-length Unicode character string.	NCHAR(*n*)
NVARCHAR(*n*)	NVARCHAR(*n*)	A varying-length Unicode character string.	NVARCHAR(*n*)
REAL	REAL	A floating-point number.	REAL
SMALLINT	SMALLINT	A small integer.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)[2]
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
TINYINT	BYTEINT	A tiny integer.	TINYINT
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string data.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 Due to the ODBC-style interface that is used to communicate with the Netezza server, fractional seconds are lost in the data transfer from server to client.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for ODBC

The following table lists the data type support for a data source that is compliant with ODBC.

For data source-specific information about ODBC SQL data types, see the specific ODBC data source documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for ODBC in *SAS Cloud Analytic Services: User's Guide*.

Table A21.17 *Mapping of FedSQL Data Types to Data Types Supported by ODBC*

Data Type Definition Keyword[1]	ODBC SQL Identifier	Description	Data Type Returned
BIGINT	SQL_BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	SQL_BINARY	A fixed-length binary string.	BINARY(*n*)
[2]	SQL_BIT	A single-bit binary value.	[2]
CHAR(*n*)[3]	SQL_CHAR	A fixed-length character string.	CHAR(*n*)
DATE	SQL_TYPE_DATE	A date values.	DATE
DECIMAL|NUMERIC(*p*,*s*)	SQL_DECIMAL|SQL_NUMERIC	A signed, fixed-point decimal number.	DECIMAL|NUMERIC(*p*,*s*)[4]
DOUBLE	SQL_DOUBLE	A signed, double precision, floating-point number.	DOUBLE
FLOAT	SQL_FLOAT	A signed, double precision, floating-point number.	DOUBLE

Data Type Definition Keyword[1]	ODBC SQL Identifier	Description	Data Type Returned
[2]	SQL_GUID	A globally unique identifier.	[2]
INTEGER	SQL_INTEGER	A regular signed, exact whole number.	INTEGER
[2]	SQL_INTERVAL	An interval between two years, months, days, dates or times.	[2]
[2]	SQL_LONGVARBINARY	A varying-length binary string.	[2]
[2]	SQL_LONGVARCHAR	A varying-length Unicode character string.	[2]
NCHAR(*n*)	SQL_WCHAR	A fixed-length Unicode character string.	NCHAR(*n*)
NVARCHAR(*n*)	SQL_WVARCHAR	A varying-length Unicode character string.	NVARCHAR(*n*)
REAL	SQL_REAL	A signed, single precision, floating-point number.	REAL
SMALLINT	SQL_SMALLINT	A small signed, exact whole number.	SMALLINT
TIME(*p*)	SQL_TYPE_TIME	A time value.	TIME(*p*)
TIMESTAMP(*p*)	SQL_TYPE_TIMESTAMP	A date and time value.	TIMESTAMP(*p*)
TINYINT	SQL_TINYINT	A very small signed, exact whole number.	TINYINT
VARBINARY(*n*)	SQL_VARBINARY	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)[3]	SQL_VARCHAR	A varying-length character string.	VARCHAR(*n*)

Data Type Definition Keyword[1]	ODBC SQL Identifier	Description	Data Type Returned
2	SQL_WLONGVARCHAR	A varying-length Unicode character string.	2

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The ODBC SQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 When you use the CHAR(*n*) or VARCHAR(*n*) data type to store multibyte data in a DB2, Greenplum, or Oracle database, you must specify the encoding in the CLIENT_ENCODING= connection option. Or, for Oracle only, to avoid having to set the encoding, use the NCHAR or NVARCHAR data types for multibyte data instead.

4 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Oracle

The following table lists the data type support for an Oracle database.

For data source-specific information about Oracle data types, see the Oracle database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Oracle in *SAS Cloud Analytic Services: User's Guide*.

Table A21.18 *Mapping of FedSQL Data Types to Data Types Used by Oracle*

Data Type Definition Keyword[1]	Oracle Data Type	Description	Data Type Returned
BIGINT	NUMBER	A large signed, exact whole number.	BIGINT
BINARY(*n*)	RAW(*n*)	A fixed or varying-length binary string.	BINARY(*n*)
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	TIMESTAMP(*p*)[3]

Data Type Definition Keyword[1]	Oracle Data Type	Description	Data Type Returned
DECIMAL| NUMERIC(*p*,*s*)	NUMBER(*p*,*s*)	A signed, fixed-point decimal number.	DOUBLE[4]
DOUBLE	BINARY_DOUBLE	A signed, double precision floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A signed, double precision floating-point number.	DOUBLE
INTEGER	NUMBER(*p*,*s*)	A regular signed, exact whole number.	INTEGER
[2]	LONG	A varying-length character string.	[2]
NCHAR(*n*)	NCHAR(*n*)	A fixed-length Unicode character string.	NCHAR(*n*)
NVARCHAR(*n*)	NVARCHAR(*n*)	A varying-length Unicode character string.	NVARCHAR(*n*)
REAL	FLOAT	A signed, single precision floating-point number.	REAL
SMALLINT	NUMBER	A small signed, exact whole number.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIMESTAMP(*p*)[3]
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
TINYINT	NUMBER	A very small signed, exact whole number.	TINYINT
VARBINARY(*n*)	RAW(*n*)	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	VARCHAR2(*n*)[5]	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Oracle data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 The timestamp returned by the DATE and TIME data types can be changed to date and time values by using the DATEPART function with the PUT function.

4 The ORNUMERIC= connection argument and table option determine how numbers read from or inserted into the Oracle NUMBER column are treated. ORNUMERIC=YES, which is the default, indicates that non-integer values with explicit precision are treated as NUMERIC values. When BULKLOAD=YES, ORNUMERIC defaults to NO.

5 The VARCHAR2(*n*) type is supported for up to 32,767 bytes if the Oracle version is 12c and the Oracle MAX_STRING_SIZE= parameter is set to EXTENDED.

Data Types for PostgreSQL

The following table lists the data type support for a PostgreSQL database.

The BINARY, NCHAR, NVARCHAR, TINYINT, and VARBINARY data types are not supported for data type definition.

For data source-specific information about PostgreSQL data types, see the PostgreSQL database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for PostgreSQL in *SAS Cloud Analytic Services: User's Guide*.

Table A21.19 *Mapping of FedSQL Data Types to Data Types Used by PostgreSQL*

Data Type Definition Keyword[1]	PostgreSQL Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number or signed eight-byte integer.	BIGINT
[2]	BIGSERIAL	An auto-incrementing eight-byte integer.	[2]
[2]	BIT(*n*)	A fixed-length bit string.	[2]
[2]	BIT VARYING(*n*)	A varying-length bit string.	[2]
[2]	BOOLEAN	A logical Boolean (true/false) value.	[2]
[2]	BOX	A rectangular box on a plane.	[2]
[2]	BYTEA	A byte array.	[2]
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
[2]	CIDR	An IPv4 or IPv6 network address.	[2]
[2]	CIRCLE	A circle on a plane.	[2]

Data Type Definition Keyword[1]	PostgreSQL Data Type	Description	Data Type Returned
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	NUMERIC(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL| NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE PRECISION	A signed, double precision, floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A signed, double precision, floating-point number.	DOUBLE
[2]	INET	An IPv4 or IPv6 host address.	[2]
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER
[2]	INTERVAL	A time span.	[2]
[2]	LINE	An infinite line on a plane.	[2]
[2]	LSEG	A line segment on a plane.	[2]
[2]	MACADDR	A Media Access Control address.	[2]
[2]	MONEY	A currency amount.	[2]
[2]	PATH	A geometric path on a plane.	[2]
[2]	POINT	A geometric point on a plane.	[2]
[2]	POLYGON	A closed geometric path on a plane.	[2]
REAL	REAL	A signed, single precision floating-point number.	REAL
[2]	SERIAL	An auto-incrementing four-byte integer.	[2]
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
[2]	SMALL SERIAL	An auto-incrementing two-byte integer.	[2]

Data Type Definition Keyword[1]	PostgreSQL Data Type	Description	Data Type Returned
[2]	TEXT	A varying-length character string.	[2]
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
[2]	TSQUERY	A text search query.	[2]
[2]	TSVECTOR	A text search document.	[2]
[2]	TXID_SNAPSHOT	User-level transaction ID snapshot.	[2]
[2]	UUID	A universally unique identifier.	[2]
VARCHAR(*n*)	CHARACTER VARYING(*n*)	A varying-length character string.	VARCHAR(*n*)
[2]	XML	XML data.	[2]

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The PostgreSQL data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Reading from Salesforce

The following table lists the data type support for reading from Salesforce. SAS/ACCESS software uses the Salesforce SOAP API to read from Salesforce. The Salesforce SOAP API returns primitive types.

The Salesforce calculated type and compound types are not supported. Examples of compound types are address and location.

For more information, see documentation for the Salesforce SOAP API.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about

CAS data type conversions, see the documentation for the SAS Data Connector for Salesforce in *SAS Cloud Analytic Services: User's Guide*.

Table A21.20 *Data Type Mapping When Reading from Salesforce*

Salesforce Field or Primitive Type	Description	Data Type Returned by FedSQL
anyType	A polymorphic data type that can be used differently throughout the interface based on context.	VARCHAR(*n*)
base64	Base-64 binary data, including attachment records, document records, and scontrol records. The Body/Binary field contains data. The BodyLength field defines length of data.	VARCHAR(*n*)[1]
boolean	A Boolean value.	TINYINT
byte	A set of bits.	TINYINT
combobox	A set of enumerated values that allows the user to define a value that is not in the list.	VARCHAR(*n*)
currency	A currency value.	DOUBLE
DataCategoryGroupReference	A reference to a data category group or category unique name on Article and Question objects.	VARCHAR(*n*)
date	A date value.	DATE[2]
dateTime	A timestamp.	TIMESTAMP[2]
double	A signed, double precision, floating-point number.	DOUBLE[3]
email	An email address.	VARCHAR(*n*)
encryptedstring	An encrypted text string. The strings have a maximum length of 175 characters.	VARCHAR(*n*)
ID	A primary key field for the object.	VARCHAR(*n*)
int	A regular signed, exact whole number whose size varies depending on field settings.	BIGINT

Salesforce Field or Primitive Type	Description	Data Type Returned by FedSQL
JunctionIdList	A string array of referenced IDs values that represents the many-to-many relationship of an underlying junction entity.	VARCHAR(*n*)
masterrecord	Identifier of a record that is merged and the original records are deleted.	VARCHAR(*n*)
multipicklist	A set of enumerated values from which multiple values can be selected. The selected values are returned as a string of semicolon-separated values.	VARCHAR(*n*)
percent	A percentage value.	DOUBLE
phone	A phone number.	CHAR(40)
picklist	A set of enumerated values from which one value can be selected.	VARCHAR(*n*)
reference	A cross-reference for a different object. Analogous to a foreign key in SQL.	VARCHAR(*n*)
String	A text string whose maximum size varies depending on field settings.	CHAR(*n*)
textarea	A string that is displayed as a multiline text field.	VARCHAR(*n*)
Time	A time value.	TIME[2]
url	A Uniform Resource Locator (URL) value.	VARCHAR(*n*)

1 base64 fields remain in base64 format as a VARCHAR type.

2 The earliest valid date is 1700-01-01T00:00:00Z GMT, or just after midnight on January 1, 1700. The latest valid date is 4000-12-31T00:00:00Z GMT, or just after midnight on December 31, 4000. These values are offset by time zone. For example, in the Pacific time zone, the earliest valid date is 1699-12-31T16:00:00, or 4:00 PM on December 31, 1699.

3 double columns that match the precision and scale described for the numeric types in "Data Types for Writing to Salesforce" on page 2121 are mapped as shown in that table. For example, a double column that has a precision of 10 and scale of 0 is mapped to INTEGER.

Data Types for Writing to Salesforce

The following table lists the data type support for writing to Salesforce.

SAS supports the Winter '19 release of Salesforce and later.

The BINARY, FLOAT, and VARBINARY data types are not supported for data definition.

For more information, see documentation for the Salesforce Metadata API.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Salesforce in *SAS Cloud Analytic Services: User's Guide*.

Table A21.21 *Data Type Mapping When Writing to Salesforce*

Data Type Definition Keyword	Salesforce Custom Field Type	Description	Data Type Returned by CREATE TABLE with AS Expression
BIGINT	Number	A number with precision 18, scale 0.	BIGINT
CHAR(*n*)[1]	Text	A character string that is less than or equal to 255 characters.	CHAR(*n*)
DATE	Date	A date value.[2]	DATE
DECIMAL| NUMERIC(*p,s*)	Number	A number with precision and scale.	DOUBLE
DOUBLE	Number	A number with precision 18, scale 4.	DOUBLE
INTEGER	Number	A number with precision 10, scale 0.	INTEGER
NCHAR(*n*)	Text	A Unicode character string of fixed length.	CHAR(*n*)
NVARCHAR(*n*)	Text	A Unicode character string of varying length.	VARCHAR(*n*)
REAL	Number	A number with precision 18, scale 4.	DOUBLE

Data Type Definition Keyword	Salesforce Custom Field Type	Description	Data Type Returned by CREATE TABLE with AS Expression
SMALLINT	Number	A number with precision 5, scale 0.	SMALLINT
TIME	Time	A time value. [2]	TIME
TIMESTAMP	Datetime	A timestamp. [2]	TIMESTAMP
TINYINT	Number	A number with precision 3, scale 0.	TINYINT
VARCHAR(*n*)[3]	LongTextArea	A character string that is greater than 255 characters and less than 32K characters.	VARCHAR(*n*)

1 CHAR(*n*) values where *n* is greater than 255 characters are created as VARCHAR(*n*).

2 The earliest valid date is 1700-01-01T00:00:00Z GMT, or just after midnight on January 1, 1700. The latest valid date is 4000-12-31T00:00:00Z GMT, or just after midnight on December 31, 4000. These values are offset by time zone. For example, in the Pacific time zone, the earliest valid date is 1699-12-31T16:00:00, or 4:00 PM on December 31, 1699.

3 VARCHAR(*n*) values where *n* is less than or equal to 255 characters are created as CHAR(*n*).

Data Types for SAP

The following table lists the data type support for an SAP system.

For an SAP system, no data types are supported for column definition. Native ABAP SAP data types are mapped to similar data types for data retrieval only.

For data source-specific information about the ABAP SAP data types, see the SAP system database documentation.

Note: This data source is not supported on the CAS server.

Table A21.22 *Mapping of SAP Data Types to FedSQL Data Types*

ABAP SAP Data Type	Description	FedSQL Data Type Used For Data Retrieval
ACCP	A posting period.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system

ABAP SAP Data Type	Description	FedSQL Data Type Used For Data Retrieval
CHAR	A fixed-length character string.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system
CLNT	A client field.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system
CUKY	A currency key. Fields of this type are referenced by fields of type CURR.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system
CURR	A currency field. Corresponds to the DEC field. Field refers to a field of type CUKY.	CHAR(*n*)
DATS	A date value.	DATE
DEC	A signed, fixed-point decimal number.	CHAR(*n*)
FLTP	A floating-point number.	DOUBLE
INT1	A very small signed, exact whole number.	TINYINT
INT2	A small signed, exact whole number.	SMALLINT
INT4	A regular signed, exact whole number.	INTEGER
INT8	A large signed, exact whole number.	BIGINT
LANG	A language key, which has its own field format for special functions. The conversion exit ISOLA converts the value to be displayed to that of the database and the opposite is true.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system
LCHR	A fixed-length character string.	VARCHAR(*n*) for non-Unicode SAP system; NVARCHAR(*n*) for Unicode SAP system
LRAW	An un-interpreted varying-length byte string.	VARBINARY(*n*)

ABAP SAP Data Type	Description	FedSQL Data Type Used For Data Retrieval
NUMC	A text string.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system
PREC	The precision of a QUAN field.	CHAR(*n*)
QUAN	A quantity that corresponds to the DEC field.	CHAR(*n*)
RAW	An un-interpreted byte string.	BINARY
TIMS	A time value.	TIME(*p*)
UNIT	A units key that is referenced by a QUAN data type.	CHAR(*n*) for non-Unicode SAP system; NCHAR(*n*) for Unicode SAP system
VARC	A varying-length character string data. As of SAP release 3.0, creating fields of this data type is no longer supported. Existing fields with this data type can be used, except in a WHERE condition in the SELECT statement.	VARCHAR(*n*) for non-Unicode SAS system; NVARCHAR(*n*) for Unicode SAP system

Data Types for SAP HANA

The following table lists the data type support for an SAP HANA database.

For data source-specific information about the SAP HANA data types, see the SAP HANA database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for SAP HANA in *SAS Cloud Analytic Services: User's Guide*.

Table A21.23 *Mapping of FedSQL Data Types to Data Types Used by SAP HANA*

Data Type Definition Keyword [1]	SAP HANA Data Type	Description	Data Type Returned
[2]	ALPHANUM(*n*)	A varying-length character string.	NVARCHAR(*n*)
BIGINT	BIGINT	A 64-bit integer.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary value.	BINARY(*n*)
[2]	BLOB	A varying-length binary large object string.	[2]
CHAR(*n*)	CHAR(*n*)	A varying-length character string.	CHAR(*n*)
[2]	CLOB	A varying-length character large object string.	[2]
DATE	DATE	A year, month, and day value.	DATE
DECIMAL| NUMERIC(**p**,*s*)	DECIMAL(*p*,*s*)	A signed, exact, fixed-point decimal number.	DECIMAL(*p*,*s*)[3]
DOUBLE	DOUBLE	A double precision floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A double precision floating-point number.	DOUBLE
INTEGER	INTEGER	A 32-bit integer.	INTEGER
NCHAR(*n*)	NCHAR(*n*)	A fixed-length Unicode character string.	NCHAR(*n*)
[2]	NCLOB	A fixed-length character large object string.	[2]
NVARCHAR(*n*)	NVARCHAR(*n*)	A varying-length Unicode character large object string.	NVARCHAR(*n*)
REAL	REAL	A floating-point number.	REAL
[2]	SECONDATE	A date and time value.	[2]

Data Type Definition Keyword [1]	SAP HANA Data Type	Description	Data Type Returned
[2]	SHORTTEXT(*n*)	A varying-length character string.	NVARCHAR(*n*)
[2]	SMALLDECIMAL(*p*,*s*)	A floating-point decimal number.	DECIMAL(*p*,*s*)[3]
SMALLINT	SMALLINT	A 16-bit integer.	SMALLINT
[2]	TEXT	A varying-length Unicode character large object string.	[2]
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
TINYINT	TINYINT	An unsigned 8-bit integer.	TINYINT
VARBINARY(*n*)	VARBINARY(*n*)	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The SAP HANA data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for SAP IQ

The following table lists the data type support for an SAP IQ database.

For data source-specific information about the SAP IQ database data types, see the SAP IQ database documentation.

Note: This data source is not supported on the CAS server.

Table A21.24 Mapping of FedSQL Data Types to Data Types Used by SAP IQ

Data Type Definition Keyword[1]	SAP IQ Data Type	Description	Data Type Returned
BIGINT	BIGINT	64-bit integer.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY(*n*)
[3]	BIT	Integer that stores only the values 0 or 1.	[3]
CHAR(*n*)	CHAR(*n*)	A varying-length character string.	VARCHAR(*n*)
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p,s*)	DECIMAL(*p,s*)	A signed, exact, fixed-point decimal number.	DECIMAL(*p,s*)[4]
DOUBLE	DOUBLE	Double-precision floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	Double-precision floating-point number.	DOUBLE
INTEGER	INTEGER	32-bit integer.	INTEGER
[2]	LONG BINARY	A varying-length binary string.	VARBINARY(*n*)
REAL	REAL	A floating-point number.	REAL
SMALLINT	SMALLINT	16-bit integer.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
TINYINT	TINYINT	An unsigned eight-bit integer.	TINYINT
VARBINARY(*n*)	VARBINARY(*n*)	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	CHAR(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The SAP IQ data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 The SAP IQ data type cannot be defined or retrieved.

4 The DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision.

Data Types for SingleStore

The following table lists the data type support for a SingleStore database.

The NCHAR, NVARCHAR, REAL, and VARBINARY data types are not supported for data type definition.

For data source-specific information about SingleStore data types, see the SingleStore database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for SingleStore in *SAS Cloud Analytic Services: User's Guide*.

Table A21.25 *Mapping of FedSQL Data Types to Data Types Used by SingleStore*

Data Type Definition Keyword[1]	SingleStore Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY(*n*)
[2]	BLOB	A binary large object string.	[2]
CHAR(*n*)	CHAR(*n*)[3]	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
[2]	DATETIME	A date and time value.	[2]
DECIMAL| NUMERIC(*p*,*s*)	DECIMAL(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL(*p*,*s*)[4]
DOUBLE	DOUBLE	A signed, double precision, floating-point number.	DOUBLE

Data Type Definition Keyword[1]	SingleStore Data Type	Description	Data Type Returned
[2]	ENUM(*values*)	A character value from a list of allowed values.	[2]
FLOAT	FLOAT(*p*)	A signed, double precision, floating-point number.	DOUBLE
INTEGER	INT	A regular signed, exact whole number.	INTEGER
[2]	JSON	A varying-length character string in JSON format.	VARCHAR
[2]	LONGBLOB	A binary large object string of varying length.	[2]
[2]	LONGTEXT	A text string of varying length.	[2]
[2]	MEDIUMBLOB	A binary large object string of varying length.	[2]
[2]	MEDIUMINT	A regular signed, exact whole number.	[2]
[2]	MEDIUMTEXT	A varying-length character string.	[2]
[2]	SET(*values*)	A character value from a list of allowed values.	[2]
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
[2]	TEXT	A text string.	[2]
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	DATETIME(*p*)	A date and time value.	TIMESTAMP(*p*)
[2]	TINYBLOB	A binary large object string of varying length.	[2]
TINYINT	TINYINT	A very small signed, exact whole number.	TINYINT

Data Type Definition Keyword[1]	SingleStore Data Type	Description	Data Type Returned
[2]	TINYTEXT	A text string of varying length.	[2]
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The SingleStore data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 DS2 uses ANSI SQL rules for handling blank spaces in fixed character values. MySQL 8 treats trailing blank spaces as significant values by default. This difference interferes with character comparisons that are performed when using FedSQL statements in DS2. When using DS2 to issue FedSQL statements on MySQL 8 CHAR() data, it is necessary to use the TRIM function in the FedSQL statement to ensure that the data is read correctly. For information about the locations in which FedSQL statements are supported in DS2, see "Using DS2 and FedSQL" in *SAS DS2 Programmer's Guide*.Also see: "Example: Filter Trailing Spaces from MySQL 8 CHAR() Data" on page 2229. MySQL 8 uses utf8mb4_0900_ai_ci as the default collation for comparisons.

4 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Snowflake

The following table lists the data type support for Snowflake.

The FedSQL NCHAR, NVARCHAR, and TINYINT data types are not supported for data definition.

For data source-specific information about the Snowflake data types, see the Snowflake documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Snowflake in *SAS Cloud Analytic Services: User's Guide*.

Table A21.26 *Mapping of FedSQL Data Types to Data Types Used by Snowflake*

Data Type Definition Keyword	Snowflake Data Type	Description	Data Type Returned
[1]	ARRAY	A dense or sparse array of arbitrary size whose	VARCHAR

Data Type Definition Keyword	Snowflake Data Type	Description	Data Type Returned
		values are a value of the VARIANT type.	
BIGINT	BIGINT	A 64-bit integer.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY
[1]	BOOLEAN	A true, false, or unknown (null) value.	BINARY
CHAR(*n*)	VARCHAR(1)	A fixed-length character string.	VARCHAR
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	NUMBER(*p*,*s*)	A signed, exact, fixed-point decimal number.	DECIMAL(*p*,*s*)[2]
DOUBLE	FLOAT	A double precision floating-point number.	DOUBLE
FLOAT	FLOAT, FLOAT4, FLOAT8	A double precision floating-point number.	DOUBLE
INTEGER	NUMBER without precision and scale	A 32-bit integer.	INTEGER
[1]	OBJECT	A collection of key-value pairs, where the key is a non-empty string, and the value is a value of the VARIANT type.	VARCHAR
REAL	FLOAT	A floating-point number.	FLOAT
SMALLINT	NUMBER without precision and scale	A 16-bit integer.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP, TIMESTAMP_LTZ, TIMESTAMP_NTZ, TIMESTAMP_TZ	A date and time value.	TIMESTAMP(*p*)

Data Type Definition Keyword	Snowflake Data Type	Description	Data Type Returned
VARBINARY(*n*)	VARBINARY	A varying-length binary string.	BINARY
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string. The default (and maximum) length is 16,777,216.	VARCHAR
[1]	VARIANT	A universal data type that can store values of any other Snowflake data type, including OBJECT and ARRAY, up to 16 MB.	VARCHAR

1 The Snowflake data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

2 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Spark

The following table lists the data type support for Apache Spark.

The NCHAR and NVARCHAR data types are not available for data definition.

For data source-specific information about Spark SQL data types, see the Spark SQL documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Spark in *SAS Cloud Analytic Services: User's Guide*.

Table A21.27 *Mapping of FedSQL Data Types to Data Types Used by Apache Spark*

Data Type Definition Keyword	Spark Data Type	Description	Data Type Returned
[1]	ARRAY<*data-type*>	An array of integers (indexable lists).	STRING[5, 7]

Data Type Definition Keyword	Spark Data Type	Description	Data Type Returned
BIGINT	BIGINT	A signed eight-byte integer, from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.	BIGINT
BINARY(*n*)	BINARY	A varying-length binary string up to 32K.	BINARY
[1]	BOOLEAN	A textual true or false value.	TINYINT
CHAR(*n*)	CHAR(*n*)[9]	A character string up to 255 characters. [3]	CHAR
DATE	DATE[2]	An ANSI SQL date value.	DATE
DECIMAL/ NUMERIC(*p,s*)	DECIMAL	A fixed-point decimal number, with 38 digits precision.	DECIMAL(*p,s*)[4]
DOUBLE	DOUBLE	An eight-byte, double precision floating-point number.	DOUBLE
FLOAT	FLOAT	An eight-byte, double precision floating-point number.	DOUBLE
INTEGER	INTEGER	A signed four-byte integer.	INTEGER
[1]	MAP<*primitive-type*, *data-type*>	An associative array of key-value pairs.	STRING[5, 7]
REAL	DOUBLE	A 64-bit double precision, floating-point number.	DOUBLE
SMALLINT	SMALLINT	A signed two-byte integer, from -32,768 to 32,767.	SMALLINT
[1]	STRING	A varying-length character string.	VARCHAR(*n*)[5, 6]

Data Type Definition Keyword	Spark Data Type	Description	Data Type Returned
[1]	STRUCT<*col-name*: *data-type*>	A structure with established column elements and data types. Column elements and data types are mapped using a double-dot (:) notation.	STRING[5, 7]
TIME(*p*)	[8]	A time value.	STRING
TIMESTAMP(*p*)	TIMESTAMP	A UNIX timestamp with optional nanosecond precision.	TIMESTAMP[(*p*)]
[1]	TIMESTAMP_NTZ[10]	Timestamp with no timezone.	TIMESTAMP
TINYINT	TINYINT	A signed one-byte integer, from -128 to 127.	TINYINT
VARBINARY	BINARY	A varying-length binary string up to 32K.	BINARY
VARCHAR(*n*)	VARCHAR(*n*)[9]	A varying-length character string.	VARCHAR(*n*)[5]

1 The Spark data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

2 The supported date values are between January 1, 0001 and December 31, 9999. Date values later than 9999 are read back as null values.

3 If you specify CHAR with a value greater than 255 characters, the column is created as VARCHAR(*n*) instead.

4 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

5 The maximum length of VARCHAR(*n*) and the Hive complex types is determined by the DBMAX_TEXT= data source connection option.

6 SASFMT TableProperties are applied when reading STRING columns.

7 The complex types ARRAY, MAP, STRUCT are read as their STRING representation of the underlying complex type. ARRAY values are read back within brackets, for example: [1, 2, 4]. STRUCT and MAP values are read back within braces, for example: {"firstname":"robert","nickname":"bob"}.

8 Spark does not support the TIME(*p*) data type. When data is read from Spark, STRING columns that have SASFMT TableProperties defined that specify the SAS TIME8. format are converted to the TIME(*p*) data type. When the TIME type is used for data definition, it is mapped to a STRING column with SASFMT TableProperties. Fractional seconds are not preserved. For more information about SASFMT TableProperties, see "SAS Table Properties for Spark and Hadoop" in *SAS/ACCESS for Relational Databases: Reference*.

9 In Apache Spark 2.0.0, the maximum number of columns allowed in a Spark table might be limited by https://issues.apache.org/jira/browse/SPARK-18016 .

10 The TIMESTAMP_NTZ type is supported with Databricks only and when using Databricks Runtime 13.3 LTS and above.

Data Types for Teradata

The following table lists the data type support for a Teradata database.

The NCHAR, NVARCHAR, and REAL data types are not supported for data type definition.

For data source-specific information about the Teradata data types, see the Teradata database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Teradata in *SAS Cloud Analytic Services: User's Guide*.

Table A21.28 *Mapping of FedSQL Data Types to Data Types Used by Teradata*

Data Type Definition Keyword[1]	Teradata Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number.	BIGINT
BINARY(*n*)	BYTE(*n*)	A fixed-length binary string.	BINARY(*n*)
[2]	BLOB	A large binary object.	[2]
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
[2]	CLOB	A large character object.	[2]
DATE	DATE	A date value.	DATE
DECIMAL(*p*,*s*)	DECIMAL(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL(*p*,*s*)[3]
NUMERIC(*p*,*s*)	NUMBER(*p*,*s*)	A signed, varying-length decimal number.	NUMERIC(*p*,*s*)[3]
DOUBLE	FLOAT	A signed, double precision, floating-point number.	DOUBLE
FLOAT	FLOAT(*p*)	A signed, double precision, floating-point number.	DOUBLE

Data Type Definition Keyword[1]	Teradata Data Type	Description	Data Type Returned
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER
[2]	LONG VARCHAR	A varying-length character string.	[2]
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
TINYINT	BYTEINT	A very small signed, exact whole number.	TINYINT
VARBINARY(*n*)	VARBYTE(*n*)	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	VARCHAR(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Teradata data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL and NUMERIC data types are supported in requests that can be fully passed down to the data source. DECIMAL and NUMERIC columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Vertica

The following table lists the data type support for a Vertica database.

The NCHAR and NVARCHAR data types are not supported for data definition.

For data source-specific information about Vertica data types, see the Vertica database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Vertica in *SAS Cloud Analytic Services: User's Guide*.

Table A21.29 *Mapping of FedSQL Data Types to Data Types Used by Vertica*

Data Type Definition Keyword [1]	Vertica SQL Identifier	Description	Data Type Returned
BIGINT	BIGINT	A signed 64-bit integer, requiring 8 bytes of storage.	BIGINT
BINARY(*n*)	BINARY(*n*)	A fixed-length binary string.	BINARY(*n*)
[2]	BOOLEAN	A logical Boolean (true/false) value.	[2]
[2]	BYTEA	A varying-length binary string.	[2]
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
[2]	DATETIME	A date and time value with or without time zone.	TIMESTAMP(*p*)
DECIMAL|NUMERIC(*p*,*s*)	DECIMAL|NUMERIC(*p*,*s*)	A signed, fixed precision and scale numbers. Default precision and scale: 37, 15.	DECIMAL|NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE PRECISION	A signed 64-bit IEEE floating point number, requiring 8 bytes of storage.	DOUBLE
FLOAT	FLOAT, FLOAT8	A signed 64-bit IEEE floating point number, requiring 8 bytes of storage.	DOUBLE
INTEGER	INTEGER	A signed 64-bit integer, requiring 8 bytes of storage.	BIGINT
[2]	INTERVAL	A time span.	[2]
[2]	INTERVAL DAY TO SECOND	A time span.	[2]

Data Type Definition Keyword [1]	Vertica SQL Identifier	Description	Data Type Returned
[2]	INTERVAL YEAR TO MONTH	A time span.	[2]
[2]	LONG VARCHAR	A varying-length, raw byte value, such as spatial data.	[2]
[2]	LONG BINARY	A long, varying-length binary string.	[2]
[2]	MONEY(*p*,*s*)	A money or currency value of signed, fixed precision and scale. Default precision and scale: 18, 4.	[2]
[2]	NUMBER(*p*,*s*)	A signed, fixed precision and scale numbers. Default precision and scale: 38,0.	[2]
[2]	RAW	A varying-length binary string.	[2]
REAL	REAL	A signed 64-bit IEEE floating point number, requiring 8 bytes of storage.	DOUBLE
[2]	SMALLDATETIME	A date and time value with or without time zone.	TIMESTAMP(*p*)
SMALLINT	SMALLINT	A signed 64-bit integer, requiring 8 bytes of storage.	BIGINT
TIME(*p*)	TIME(*p*)	A time value without time zone.	TIME(*p*)
[2]	TIMETZ	A time value with time zone.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP	A date and time value without time zone.	TIMESTAMP(*p*)

Data Type Definition Keyword [1]	Vertica SQL Identifier	Description	Data Type Returned
[2]	TIMESTAMPTZ	A date and time value with time zone.	TIMESTAMP(*p*)
TINYINT	TINYINT	A signed 64-bit integer, requiring 8 bytes of storage.	BIGINT
VARBINARY(*n*)	VARBINARY	A varying-length binary string.	VARBINARY(*n*)
VARCHAR(*n*)	VARCHAR(*n*), TEXT	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Vertica data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Data Types for Yellowbrick

The following table lists the data type support for a Yellowbrick database.

The BINARY, NCHAR, NVARCHAR, TINYINT, and VARBINARY data types are not supported for data type definition.

For data source-specific information about Yellowbrick data types, see the Yellowbrick database documentation.

Note: The information in this table does not apply to data that is processed in CAS. Data that is loaded into CAS is converted to CAS data types. For information about CAS data type conversions, see the documentation for the SAS Data Connector for Yellowbrick in *SAS Cloud Analytic Services: User's Guide*.

Table A21.30 Mapping of FedSQL Data Types to Data Types Used by Yellowbrick

Data Type Definition Keyword[1]	Yellowbrick Data Type	Description	Data Type Returned
BIGINT	BIGINT	A large signed, exact whole number or a signed eight-byte integer.	BIGINT
[2]	BOOLEAN	A logical Boolean (true/false) value.	[2]
CHAR(*n*)	CHAR(*n*)	A fixed-length character string.	CHAR(*n*)
DATE	DATE	A date value.	DATE
DECIMAL| NUMERIC(*p*,*s*)	NUMERIC(*p*,*s*)	A signed, fixed-point decimal number.	DECIMAL| NUMERIC(*p*,*s*)[3]
DOUBLE	DOUBLE PRECISION	A signed, double precision, floating-point number.	DOUBLE
FLOAT	DOUBLE PRECISION, FLOAT, FLOAT8	A signed, double precision, floating-point number.	DOUBLE
INTEGER	INTEGER	A regular signed, exact whole number.	INTEGER
[2]	MACADDR, MACADDR8	A Media Access Control address.	[2]
REAL	REAL, FLOAT4	A signed, single precision floating-point number.	REAL
SMALLINT	SMALLINT	A small signed, exact whole number.	SMALLINT
TIME(*p*)	TIME(*p*)	A time value.	TIME(*p*)
TIMESTAMP(*p*)	TIMESTAMP(*p*)	A date and time value.	TIMESTAMP(*p*)
[2]	UUID	A universally unique identifier.	[2]
VARCHAR(*n*)	CHARACTER VARYING(*n*)	A varying-length character string.	VARCHAR(*n*)

1 The CT_PRESERVE= connection argument, which controls how data types are mapped, can affect whether a data type can be defined. The values FORCE (default) and FORCE_COL_SIZE do not affect whether a data type can be defined. The

values STRICT and SAFE can result in an error if the requested data type is not native to the data source, or the specified precision or scale is not within the data source range.

2 The Yellowbrick data type cannot be defined, and when data is retrieved, the native data type is mapped to a similar data type.

3 In FedSQL, the DECIMAL data type is supported in requests that can be fully passed down to the data source. DECIMAL columns in requests that cannot be fully passed down to the data source are handled as DOUBLE, which can affect precision. For more information, see "Data Types" in *SAS FedSQL Language Reference*.

Appendix 2

DS2 Expressions

What Is an Expression?

An expression is a programming element that produces a data value. Expressions include operands and optional operators that form a set of instructions and resolve to a value.

An operand can be a single constant or variable, or it can be an expression. Operators are the symbols that request either a calculation, comparison, or concatenation of operands.

Here are some examples of DS2 expressions:

```
3
"col1"
a = b * c
s || 1 || z
a >= b**(c - 8)
system.put(a*5,hex.)
x'ff00effc'
```

Types of Expressions

Overview of Expressions

The basic type of expression is the primary expression. Expressions that combine expressions (primary or compound) using operators are compound expressions. Expressions can invoke a DS2 construct, such as a function expression, or a method expression. Expressions can affect the scope of a function or variable, such as the "SYSTEM Expression" and the THIS expression. The IN expression returns a truth value based on whether the result of an expression is contained in a list.

Whether an expression is simple or compound, invokes a construct, or is global in scope, all expressions have a value and a data type. The data type of an expression constrains the values that an expression, such as a variable or function, might take. When DS2 encounters a compound expression, it follows rules to determine the order in which to evaluate each part of the expression.

Note: In logical operations, a missing value in any expression, such as an IF expression, evaluates to False in SAS mode. A null value evaluates to neither true nor false in ANSI mode. If you run this example in SAS mode, `False` is written to the SAS log. If you run this example is ANSI mode, `Null` is written to the SAS log.

```
proc ds2;
data _null_;
   declare double d;
   method init();
     if d then put 'True';
       else if not d then put 'False';
       else put 'Null';
   end;
   enddata;
run;
quit;
```

Primary Expression

In their simplest form, primary expressions are identifiers, numbers, character strings, binary and hexadecimal constants, literal values, date and time values, and null values.

```
a
"var_a"
5.33
'Company'
date '2007-08-24'
```

The following table shows the basic primary expressions, their data type(s), and an example.

Table A22.1 *Data Types and Examples of Primary Expressions*

Type of Expression	Short Description	Data Type	Example
Binary Constant	Binary and hexadecimal constants	VARBINARY	`x'FE'` `b'01000011'`
Character Constant	Character string	CHAR, VARCHAR	`'New Report'` `a='Stock';` `b='Report';` `1`
National Character Constant	National Character string	NCHAR, NVARCHAR	`n'New Report'` `a=n'Stock';` `b=n'Report';` `1`
SYSTEMTHIS	System, THIS	The resolved type of the expression	`system.put(x,5.)` `this.s`
Date / time Constant	Date and time values	DATE, TIME, TIMESTAMP[2]	`date'2023-01-01'` `time'20:44:59'` `timestamp'2023-02-07 07:00:00.7569'`
Identifier	Provides a name for various language elements	The declared or default type. The default is DOUBLE.	`a` `"part1"`
Integer Constant	Integer numbers	INTEGER, BIGINT	`123`

Type of Expression	Short Description	Data Type	Example
New	Instantiates a package method	The resolved type of the expression	`a=_new_ package-name();` [1]
Fractional Constant	Floating point numbers	DOUBLE, FLOAT, REAL	`5.` `4.3`
Null Constant	Null expression	none	`NULL`
Parentheses	Operator and operands enclosed in parentheses for higher evaluation precedence	The resolved type of the expression enclosed in parentheses.	`(x)` `(a + b) - c` [1]
Missing Constant	SAS missing numeric expression	DOUBLE	`.` `.A`
Numeric Constant	Exact numeric numbers	DECIMAL, NUMERIC	`99n` `12345678901234567890123456789012345678901234567890.12N`

1 For the purpose of the example, the primary expression is contained in an expression or an assignment statement. The example expression is highlighted.

2 The TO_DOUBLE function can be used in a compound expression to generate a DOUBLE value that encodes a SAS date, time, or datetime value.

Compound Expression

A compound expression combines expressions and operators to create a more expansive expression, as in these expressions:

```
a + b * -c - 5
a = b = 5
x | y & a < c * d
x**y**z - 9 >= f
z >< c + e <> u**y * 10
x || c + 7
a in (1,2,3)
```

Evaluation of compound expressions is based on the operator order of precedence, as shown in Table A2.7 on page 2171, and the data types of the primary expressions. Before any calculations can be done, operand data types must be the same general data type: numeric, character, binary, or date/time. If the data types are the same, processing continues. If they are not the same, the operand data types are converted based on the operator and the data type of the operands.

To understand how the operator order of precedence and data types of the primary expressions are evaluated, consider the expression `a + b / -c - 5`. This expression has four operators:

- binary + operator
- binary / operator
- unary - operator
- binary - operator

Operator precedence determines the order of evaluation of the operations. Looking at Table A2.7 on page 2171, the unary - operator has order of precedence 2, the binary / operator has order of precedence 3, and the binary + operator and binary - operator both have order of precedence 4. When two operators have the same order of precedence, the associativity rule determines the order of evaluation. The binary + operator and the binary - operator have left to right associativity. Therefore, the above expressions are grouped for evaluation as follows:

```
((a + (b / (-c))) - 5)
```

Type conversion also affects the evaluation of an operation. In binary arithmetic operations, both operands must be the same type. If the operands are not the same type, the DS2 compiler converts one operand to the same type as the other operand using the type conversion for arithmetic expressions precedence rules.

Table A22.2 *Data Type Conversions for Arithmetic Operations*

Precedence	Data Type of Either Operand	Expression Data Type
1	DOUBLE, REAL	DOUBLE
2	DECIMAL, NUMERIC	DECIMAL, NUMERIC
3	BIGINT	BIGINT
4	all other numeric data types	INTEGER

Assuming the following:

- a is a DOUBLE variable with value 1.35
- b is an INTEGER variable with value 2
- c is an INTEGER variable with value 3

Here is how the expression is evaluated:

1. Since c is the INTEGER value 3, -c evaluates to the INTEGER value -3.
2. Since b is the INTEGER value 2 and -c evaluated to the INTEGER value -3, the expression `b/-c` becomes `2/-3`, which evaluates to INTEGER value 0.
3. Since a is the DOUBLE value 1.35 and the expression `b/-c` evaluated to the INTEGER value 0, the INTEGER value 0 is converted to a DOUBLE value 0.0. The expression `a + b/-c` becomes `1.35 + 0.0`, which evaluates to the DOUBLE value 1.35.
4. Since the expression `a + b /-c` evaluated to the DOUBLE value 1.35 and 5 is an INTEGER value, the INTEGER value 5 is converted to the DOUBLE value 5.0.

The expression `a + b/-c - 5` becomes `1.35 - 5.0`, which evaluates to the DOUBLE value -3.65.

A non-numeric operand in an arithmetic operation is coerced to DOUBLE. CHAR + INT have an expression type of DOUBLE, because the CHAR operand is coerced to DOUBLE. DOUBLE + INT results in an expression data type of DOUBLE, because DOUBLE has a higher precedence than INTEGER.

For more information about data type conversion, see "DS2 Type Conversions" in *SAS DS2 Programmer's Guide*.

As another example, consider the expression `a = b = 5`. The first equal sign (=) is an assignment operator. The second equal sign is a logical equality operator. If `b` is a value other than 5, then `b=5` is evaluated to 0. Therefore, `a` is assigned a value of 0. For more information, see "Example 2: Using an Expression with Multiple Equal Signs" on page 1317.

DOT Operator Expression

A dot operator expression accesses package data from code that is outside of the package.

The syntax for a DOT operator expression is as follows:

package-variable.[*package-attribute* | *package-method(arguments)*]

package-variable1.*package-variable2*....*package-variableN*.[*package-attribute* | *package-method(arguments)*]

. (dot)
accesses the package attribute or calls the package method that is specified as the right-hand operand from the package variable that is referenced by the left-hand operand.

package-attribute
specifies an attribute of the package that is referenced by the left-hand operand. A package attribute is a global variable that is defined within the package. This global variable can be a scalar variable or an array variable of the package. Dot notation supports accessing variable array attributes, standard temporary array attributes, and dynamic temporary array attributes.

package-variable
specifies an instantiation of a package whose attribute or method you want to access.

Note This can be a scalar package variable or an element of an array package variable. For more information, see "DECLARE PACKAGE Statement".

package-method(arguments)
specifies a method of the package variable that is referenced by the left-hand operand.

The left-hand operand of the dot operator must be a scalar package variable or an element of an array package variable. If the left-hand operand is null (that is, the

package variable does not reference a package instance), then a fatal runtime error results from the dot operation.

The right-hand operand of the dot operator must be either an attribute or a method of the package that is referenced by the left-hand operand. If the right-hand operand of a dot operator is an attribute that is a scalar package variable or an element of an array package variable, then the result of the dot operator can itself be used as the left-hand operand of a subsequent dot operation. An expression that specifies a package variable as the left-hand operand is a nested dot notation expression.

Nested dot notation supports accessing package data within a hierarchy of packages. An unlimited number of nested dot operations are supported as long as each left-hand operand of a nested dot operator resolves to a package variable or an element of a package array variable.

For more information, see "Dot Notation in DS2 Packages" in *SAS DS2 Programmer's Guide*.

Function Expression

A function expression invokes a function within a DS2 program. To invoke a function, use this syntax:

function-name ([*argument* [, ...*argument*]])

Functions might require arguments. If the function expression contains arguments, the argument data types are converted, if necessary, to the data types of the function **signature**, which is the argument order and data type for a function. Parentheses in the function call are required, whether the function takes arguments or the function does not take arguments. For example, the TIME function does not take arguments:

```
t = time();
```

A function expression resolves to the value returned by the function. In the function expression above, `time()` resolves to the current time of day.

Methods and functions are similar. Functions have a global scope. Methods are programming blocks and have local scope.

If the name of a function is identical to a method name, DS2 invokes the method. Functions with the same name as a method can be invoked only by using a SYSTEM expression. For more information, see "SYSTEM Expression" on page 2164.

For a list of DS2 functions, see "DS2 Functions" on page 233.

IF Expression

Overview of the IF Expression

The conditional IF expression is used to select between two values based on whether a conditional expression evaluates to true (a nonzero value) or false (zero).

To invoke an IF expression, use this syntax:

IF *expression-1* **THEN** *expression-2* **ELSE** *expression-3*

If *expression-1* is a nonzero value, the result of the IF expression is the value of *expression-2*. Otherwise, the result of the IF expression is the value of *expression-3*. Here is an example.

```
m=(if missing(u) then 0 else u);
```

The IF expression can be used wherever any other expression can be used. The precedence of an IF expression is lower than the arithmetic and logic operators; therefore, parentheses are necessary in mixed expressions like this one.

```
r = 25.5 + (if sum < 15 then -a else b*2);
```

Without the parentheses, the plus (+) operator would be evaluated first resulting in a parse error from the subexpression `25.5 + if`.

Nested IF Expressions

IF expressions can be nested to select between many values for a multi-way decision.

IF *condition-expression-1***THEN** *result-expression-1*

ELSE IF *condition-expression-2* **THEN** *result-expression-2*

...

ELSE IF *condition-expression-n* **THEN** *result-expression-n*

ELSE *result-expression-default*

The condition expressions are evaluated in order. The result of the nested IF expression chain is the associated *result-expression* of the first *condition-expression* that evaluates to true (a nonzero value). If all the *condition-expressions* evaluate to false (zero), the result of the IF expression is the *result-expression-default*. Here is an example.

```
grade = if score >= 90 then 'A'
   else if score >= 80 then 'B'
   else if score >= 70 then 'C'
   else if score >= 60 then 'D'
```

```
else if score >= 0  then 'F'
else NULL;
```

Note: Use a SELECT statement rather than a series of IF-THEN/ELSE statements when you have a long series of mutually exclusive conditions. A large number of nested IF-THEN/ELSE statements could cause an internal error. By contrast, the SELECT statement is evaluated only once, which could improve performance without causing errors.

For example, assume that a program contains many ELSE IF constructs like the following program.

```
if (e1) then …
else if (e2) then …
…
else if (en) then …
else …
```

Use this SELECT statement instead.

```
select;
when (e1): …
when (e2): …
…
when (en): …
otherwise: …
```

IF Expression Data Type

The data type of an IF expression is determined by examining the type of the first result expression, *expression-2*.

IF *expression-1* **THEN** *expression-2* **ELSE** *expression-3*

If *expression-2* is not a numeric data type, then the IF expression is assigned the type of *expression-2*.

If *expression-2* is a numeric data type, then the IF expression is assigned the wider numeric data type of *expression-2* and *expression-3*. For example, if *expression-2* is an SMALLINT and *expression-3* is a DOUBLE, then the IF expression is assigned type DOUBLE. If *expression-2* is a numeric data type and *expression-3* is not a numeric data type, then the IF expression is assigned the type of *expression-2*.

If the first result expression in a nested IF expression chain is a numeric data type, then all the result expressions are examined to find the widest numeric data type to assign as the type of the nested IF expression chain. In the following example, **t** is a TINYINT, **b** is a BIGNINT, and **d** is a DECIMAL(10,5). The 0 in the ELSE is assigned type BIGINT. Therefore, the nested IF expression chain is assigned the type decimal(10,5), the widest numeric type of TINYINT, BIGINT, and DECIMAL(10,5).

```
r = if n < 0 then t
   else if n = 0 then b
   else if n > 0 then d
```

```
   else 0;
```

Note: If 0.0 had been used for the ELSE value instead of 0, then the ELSE result would have been assigned type DOUBLE instead of type BIGINT. With the type DOUBLE ELSE expression, the widest numeric type of the result expressions would be type DOUBLE. Therefore, the nested IF expression chain would be assigned type DOUBLE instead of type decimal(10,5).

Lazy Evaluation of IF Expressions

The IF expression uses lazy evaluation for the result expressions.

IF *expression-1* **THEN** *expression-2* **ELSE** *expression-3*

For example, you could use this code to check for division by zero.

```
a = if c ne 0 then b/c else null;
```

Expression *expression-1* is always evaluated, but only one of *expression-2* or *expression-3* is evaluated. The expression that is not selected as the result of the IF expression is not evaluated. Thus, if *expression-1* is a nonzero value (true), then only *expression-2* is evaluated. If *expression-1* is zero (false), then only *expression-3* is evaluated.

Lazy evaluation also applies to the result expressions of nested IF expression chains.

```
IF condition-expression-1 THEN result-expression-1
   ELSE IF condition-expression-2 THEN result-expression-2
   ...
   ELSE IF condition-expression-n THEN result-expression-2
   ELSE result-expression-default
```

The selected result expression is the only result expression evaluated. Lazy evaluation also applies to the condition expressions. Condition expressions are evaluated in order until a condition evaluates to true (nonzero) or all conditions are evaluated. If the IF expression has *n* condition expressions and the *i*th condition is the first nonzero condition, then only the first 1 to *i* conditions are evaluated. The *i* +1 to *n* conditions are not evaluated.

IN Expression

An IN expression determines whether an expression is contained in a constant list. See "Constant List" in *SAS DS2 Programmer's Guide*.

Here is the syntax of an IN expression:

search-expression [*not-operator*] **IN** *constant-list*

The search expression matches the constant list when the search expression is equal to any of the constants in the constant list. When the NOT operator (or its aliases ~ and ^) are specified before the IN operator, the result of the IN expression is the logical negation of whether the search expression matches (see rules for the logical NOT expression on page 2172).

The result of an IN expression always has a type of INTEGER, and its value is either 1 (TRUE), 0 (FALSE), or null (unknown). The following table describes how a search match is determined.

Table A22.3 *Result Criteria for the IN Expression*

TRUE	The search expression compares equal to one or more constants in the constant list.
FALSE	The search expression compares unequal to all the constants in the constant list.
UNKNOWN	Neither of the above is true, and at least one test for equality was unknown. Typically, this happens when the search expression resolves to a value of null.

When determining whether the search expression is equal to a constant in the constant list, DS2 uses the same rules that it does in the ordinary equality expression (=). When the value of either item being compared is unknown (represented by the null value), the result of the comparison is unknown.

Special considerations for SAS mode:

- When the data type is CHAR or DOUBLE and the search expression equals the SAS missing value, it matches a missing value in the constant list.
- When a null value is specified in the constant list, it is converted to a SAS missing value.
- When the search expression must be converted to DOUBLE to match the type of one or more constants in the constant list, and the search expression has a value of null, converting the null value to a DOUBLE results in a SAS missing value. In this case, when the constant list contains a missing value, the result of the IN expression is TRUE.

In ANSI mode, it is not useful to specify a missing value in the constant list because ANSI mode converts the missing value in the constant list to a null, which is treated as an unknown value.

For more information about how DS2 processes nulls and SAS missing values, see "DS2 Modes for Nonexistent Data" in *SAS DS2 Programmer's Guide*.

The following table illustrates the processing of the IN expression in various cases, depending on whether SAS or ANSI mode is in effect. These examples assume the following variable declarations:

```
dcl char(10) my_char;
dcl double my_double;
dcl integer my_int;
```

Table A22.4 Examples of IN Expressions

Mode	Input Values	IN Expression	Result	Explanation
Either	`my_char = '3.14'`	`my_char in (3.14, 'def', 'ghi')`	1	3.14 in constant list is converted to string '3.14'
SAS	`my_double = .;`	`my_double in (., 2, 3)`	1	Missing value of search expression matches missing value in the constant list.
SAS	`my_double = .;`	`my_double in (1, 2, 3)`	0	Missing value of search expression does not match nonmissing values.
ANSI	`my_double = null;`	`my_double in (1, 2, 3)`	null	When the search expression is unknown, the value of the IN expression is unknown, regardless of the constant list.
ANSI	`my_int = -1;`	`my_int in (1, 2, 'not a number')`	null	The attempt to convert the string 'not a number' to a BIGINT type fails and results in a null value. Since there are no matches and at least one unknown comparison, the value of the entire IN expression is unknown.
SAS	`my_int = null;`	`my_int in (3, 3.14, .)`	1	The constant list must be promoted to DOUBLE to represent a fractional value; consequently, the search argument must also be converted to DOUBLE. The result is a missing value, which matches a constant in the list.

LIKE Expression

Overview of the LIKE Expression

A LIKE expression determines whether a character string matches a pattern-matching specification.

Here is the syntax of a LIKE expression:

expression [NOT] **LIKE** *pattern-matching-expression* [ESCAPE *character-expression*]

The expressions can be any character string or binary string data type.

When *expression* matches the pattern specified by *pattern-matching-expression*, a value of 1 (true) is returned. Otherwise, a value of 0 (false) is returned.

NOT LIKE returns the inverse value of LIKE. For example, if `x like y` is true, then `x not like y` is false.

The ESCAPE argument is used to search for literal instances of the percent (%) and underscore (_) characters, which are usually used for pattern matching.

Patterns for Searching

Patterns consist of three classes of characters.

Table A22.5 *Pattern-matching Characters*

Character	Description
underscore (_)	matches any single character
percent sign (%)	matches any sequence of zero or more characters **Note:** Be aware of the effect of trailing blanks. To match values, you might have to use the TRIM function to remove trailing blanks.
any other character	matches that character

Searching for Literal % and _

Because the % and _ characters have special meaning in the context of the LIKE expression, you must use the ESCAPE argument to search for these character literals in the input character string.

These examples use the values **app**, **a_%**, **a__**, **bbaa1**, and **ba_1**.

- The condition `like 'a_%'` matches **app**, **a_%**, and **a__**. The underscore (_) in the search pattern matches any single character (including the underscore), and the percent (%) in the search pattern matches zero or more characters, including '%' and '_'.
- The condition `like 'a_^%' escape '^'` matches only **a_%**. The escape character (^) specifies that the pattern search for a literal '%'.
- The condition `like 'a_%' escape '_'` matches none of the values. The escape character (_) specifies that the pattern search for an 'a' followed by a literal '%', which does not apply to any of these values.

Searching for Mixed-Case Strings

The DS2 LIKE expression is case sensitive. To search for mixed-case strings, use the UPCASE function as the following example shows:

```
upcase(str) like 'SM%'
```

LIKE Expression Examples

The following table shows examples of the matches that would result when searching these strings: `Smith, Smooth, Smothers, Smart, Smuggle`.

Table A22.6 *Examples of LIKE Expressions*

LIKE Expression Example	Matching Results
`str like 'Sm%'`	`Smith, Smooth, Smothers, Smart, Smuggle`
`str like '%th'`	`Smith, Smooth`
`str LIKE 'S__gg%'`	`Smuggle`
`str like 'S_o'`	(no matches)
`str like 'S_o%'`	`Smooth, Smothers`

LIKE Expression Example	Matching Results
`str like 'S%th'`	`Smith, Smooth`
`str not like 'Z'`	`Smith, Smooth, Smothers, Smart, Smuggle`

Method Expression

A method expression invokes a method that has been defined by the METHOD statement.

To invoke a method, use this syntax:

method-name ([*expression*[, ... *expression*]])

Methods are invoked based on the method name and signature. DS2 first identifies the method name. If a method name is identical to a function name, DS2 invokes the method. A function with the same name as a method can be invoked by using a SYSTEM expression. For more information, see "SYSTEM Expression" on page 2164.

Because DS2 allows overloaded methods, DS2 invokes the method whose arguments best match the number of arguments and the argument data types in the method signature, which is the argument order and data type for the method. The best match is the one for which the number of method parameters is equal to the number of arguments, and such that no other method signature has as many exact parameter type matches for the given argument list. If a best match is not found, an error occurs.

> **TIP** DS2 methods can support up to 1000 arguments. A DS2 method that has more than 1000 arguments can generate a compilation error.

Once the method to execute is identified, DS2 converts argument data types to the data type of the corresponding method parameter, if necessary. The method then executes.

A method expression resolves to the value returned by the method.

In the following example, methods CONCAT and ADD are defined and then invoked in the INIT() method. The highlighted expressions in the INIT() method are method expressions:

```
method concat(char(100) x, char(100) y) returns char(200);
   return trim(x)|| y;
end;

method add(double x, double y) returns double;
   return x + y;
end;

method init();
```

```
   dcl char(200) r;
   r = concat('abc', 'def');
   d = add(100,101);
end;
```

In this next example, the D method is an overloaded method. DS2 must compare the method expression arguments to the method signatures to find the best match:

```
method d(double x, double y) returns double;
   return x + y;
end;

method d(int x, int y) returns int;
   return x + y;
end;

method init();
   dcl double r;
   dcl int i;
   r = d(1.2345, 5.6789);
   i = d(99, 100);
end;
```

The first method calls the D method whose signature requires values with DOUBLE data types. The second method calls the D method whose signature requires values with INTEGER data types.

This final example shows that DS2 cannot determine whether the values in the method expression have a data type of INTEGER or DOUBLE. Because it is ambiguous, DS2 issues an error:

```
method d(int x, double y) returns double;
   return x + y;
end;

method d(double x, int y) returns double;
   return x + y;
end;

method run();
   d = d(100, 102);
end;
```

For more information, see the "METHOD Statement" on page 1391.

OF Operator

Overview and Basic Syntax

The OF operator enables you to specify variable lists and variable arrays as arguments to a function call. Submitting variable groupings as arguments to functions is the only purpose of the OF operator in a compound expression.

The syntax of the OF operator is as follows:

OF *variable-array*[*] | *variable-list*

A *variable-array*[*] is a grouping of global variables of homogenous data types. The asterisk in the subscript operator, which is required, specifies that all elements in the variable array are to be passed to the function.

A *variable-list* is an abbreviated specification that selects one or more global variables that match the abbreviation. DS2 supports several types of abbreviated variable lists. For more information, see "Types of Abbreviated Variable Lists" in *SAS DS2 Programmer's Guide*.

The OF operator transforms each element in the variable array or variable list into a comma-separated list of variable names, which become arguments to the function call. For example:

- The OF expression `OF x1-x5` is transformed into the argument list: `x1, x2, x3, x4, x5`.
- An array defined as `VARARRAY double a[6] u v w x y z;` and referenced by the OF operator as `OF a[*]` transforms into the argument list: `u, v, w, x, y, z`.

The OF operator can be interleaved with other arguments in a function call. For example, the function call

```
MAX(v1, v2, OF x1-x5, OF a[*], v3)
```

transforms to the following list of variables:

```
MAX(v1, v2, x1, x2, x3, x4, x5, u, v, w, x, y, z, v3)
```

The arguments of a function call can be any type of expression. An individual argument could be an OF operation, a subscript operation, or a more complex expression. For example, the following function call is valid:

```
MAX(OF a[*], a[1], y[3], a[1] + y[3] * 100)
```

The arguments in this function call expand to include the following:

- all elements of variable array `a`.
- the value of element 1 from array `a`. The subscripted 1 in the expression is an index to a variable in the grouping.
- the value of element 3 from an array named `y`.
- the result of the arithmetic expression a[1] + y[3] * 100.

Restrictions on the OF Operator

The *variable-array* operand of the `OF variable-array[*]` syntax must be a global variable array. The *variable-array* operand cannot be a temporary array, a varlist, or a variable array that is a parameter of a method.

Other restrictions on the OF operator include:

- can be used only with calls to DS2 functions (cannot be used with calls to user-defined methods or package methods).
- can be used only in functions that take a varying number of parameters or in functions where the number of parameters matches the number of elements in the OF list. When the function takes a fixed number of arguments, the total number of arguments after all OF lists are expanded must match the number of arguments that the function takes.
- cannot be used with functions that are specified in a WHERE clause.
- cannot be used with the DIF and LAG functions.
- The OF *variable-array*[*] syntax cannot be used as array indices. Subscript operations cannot be operands of the OF operator. When a subscript operation is preceded by the OF operator, DS2 returns the error: `Parse encountered constant when expecting '*'`. This is an example of what is not supported:

  ```
  OF a[1]
  OF v[3]
  ```

  In this example, `a` is a variable array element. That is, the subscripted 1 is an index to a variable in the grouping. `v` is a varlist. The subscripted 3 is an index to a variable in the grouping.

  Note: Only functions in the variable information category can receive an element of a varlist as an argument.

Position of the OF Operator Within Function Calls

The position of the OF operator in a function call is flexible. Each variable array and variable list can be preceded by the OF operator in an argument list. However, a single OF operator is sufficient to expand all of the variable arrays and variable lists in the argument list.

When OF is specified once and it is the first argument in the argument list, most global scalar variables in the argument list can be separated by spaces instead of commas. For example, the syntax of both of the following SUM and MAX function calls is valid:

```
SUM (OF x -- z, OF a -- c)
SUM (OF x -- z a -- c)

MAX(z, OF a[*], y)
MAX(OF z a[*] y)
```

However, function arguments that are local variables and subscript operations still need to be identified as distinct from the OF operation by using a comma. Here is an example of a function call that illustrates when commas are required:

```
proc ds2;
data _null_;
  dcl int i1 i2 i j k;
  dcl double d1 d2 d3 x y z;
  vararray double v[3] d1 d2 d3;
```

```
  varlist a [x y z i j k];
  method init();
    VSETMISSING (OF z y i:, v[1], a[3]);
  end;
enddata;
run;
quit;
```

In this example, the OF operation has three operands: `z`, `y`, and `i:`. The OF operation expands to the argument list: `z`, `y`, `i1`, `i2`, `i`. The VSETMISSING function is then called with seven arguments: `z`, `y`, `i1`, `i2`, `i`, `v[1]`, `a[3]`. Variable `d1` is the first element of variable array `v`, and variable `z` is the third element of array `a`, so VSETMISSING sets the values of variables `z`, `y`, `i1`, `i2`, `i`, `d1`, and z to missing. Because subscript operations are not operands of the OF operator, the subscript operations must be separated from the OF operator, from other arguments, and from each other using commas, even when the other arguments are separated by spaces. The commas stop the variable expansion.

Note: For some functions, the reordering of arguments can change the behavior of the function call.

Type Variable Lists and the OF Operator

Type variable lists are supported with the OF operator:

```
(OF double)
```

The OF *variable-array*[*] syntax also supports variable arrays that have a type variable list specification. Here is a variable array that has a type variable list specification. The specification selects variables of type INT:

```
vararray int x[*] int;
```

In addition, the OF *variable-array*[*] syntax supports variable arrays that have an upper bound based on the DIM of another array's bound that contains a type variable list specification. Here is a variable array that has an upper bound based on the DIM of another array's bound that contains a type variable list specification:

```
vararray int x[*] int;
vararray int  y[dim(x)];
```

Use of the OF operator is not supported when there are undeclared variables and a type variable list in any form. All variables in a DS2 program must be declared for the OF operator with a type variable list to succeed. Even if an undeclared variable is not referenced by an OF operation, the existence of the undeclared variable prevents the use of the OF operation with type variable lists.

Here is a log output of a variable list request that is not allowed:

```
20         proc ds2;
21           data _null_;
22             method init();
23               dcl double total;
24               x = 10.0; /* undeclared variable */
```

```
25              y = 20.0; /* undeclared variable */
26              total = sum(OF double);
27            end;
28          enddata;
29        run;
ERROR: Compilation error.
ERROR: Line 26: OF operator with undeclared variables and type
variable list specification is not supported.
NOTE: PROC DS2 has set option NOEXEC and will continue to prepare
statements.
```

Here is a log output of a variable array request that is not allowed:

```
1        proc ds2;
2         data _null_;
3         vararray double x[*] double;
4
5         method init();
6         a = 1.0;
7         b = 2.0;
8
9         VSETMISSING(OF x[*]);
10         end;
11         enddata;
12         run;
ERROR: Compilation error.
ERROR: Line 9: OF operator with undeclared variables and type variable list
specification is not supported.
```

Difference between the DS2 and DATA Step OF Operators

The functionality of the DS2 OF operator is similar to that of the DATA step operator. However, there are some cases where the DS2 OF operator gives different results from the DATA step OF operator. This is because of how the variable list is processed in each language. The DATA step takes only the variables up to the point of the function call. DS2 takes all the variables that match across the whole program. Here is an example where the SUM function in the DATA step program uses only the variables A1 and A4. The SUM function in the DS2 program uses the variables A1, A4, and A2.

```
/* DATA step program */
/* sums A1 and A4 with a result of 4 */
data _null_;
A1 = 1.0;
A4 = 3.0;
y = 1;
lab:
if (y = 2) then
X = SUM(OF A: );
A2 = 2.0;
if (y = 1) then do;
```

```
y = 2;
goto lab;
end;
put X=;
;
run;

/* DS2 program */
/* sums A1, A4, and A2 with a result of 6*/
proc ds2;
data X (overwrite=yes);
dcl double x A1 A2 A4 y;
method run();
A1 = 1.0;
A4 = 3.0;
y = 1;
lab:
if (y = 2) then
X = SUM(OF A: );
A2 = 2.0;
if (y = 1) then do;
y = 2;
goto lab;
end;
put X=;
end;
enddata;
run;
quit;
```

Package Method Expression

A package method expression instantiates a method that is defined in a package.

To invoke a package method expression, use this syntax:

package-variable.*method*(*method-arguments*)

The package variable can be a scalar variable or an element of an array package variable. An array package variable is a temporary array that can group multiple package instances, each of which are accessed as array elements. For more information, see the DECLARE PACKAGE statement. A package instance from an array package variable is referenced in a package method expression as follows:

package-array\[*index*\].*method*(*method-arguments*)

Note: Square brackets in the syntax convention indicate optional arguments. The escape character (\ ) before a square bracket indicates that the square bracket is required in the syntax. Array bounds must be contained by square brackets ([ ]).

Package method expressions execute in a manner similar to method expressions. That is, after DS2 has determined that the package and the method exist, the best

match of method signatures is determined, argument data types are converted if necessary, and the method executes.

> **TIP** DS2 methods can support up to 1000 arguments. A DS2 method that has more than 1000 arguments can generate a compilation error.

In the following example, the highlighted expressions are package method expressions that use a scalar package variable as the package variable:

```
declare package myadd a1() a2();
a1.sale(3,4);
a1.add(1,2);
a2.bonus(5,12);
a2.add(10,20);
```

The DECLARE PACKAGE statement declares and instantiates two package instances named a1 and a2. The first two package method expressions invoke the SALE and ADD methods in the A1 package, which was instantiated from the MYADD package. The last two package method expressions invoke the BONUS and ADD methods in the A2 package.

For an example of how an array package variable can be used, see "Declaring and Using a Packages Array".

Note: You can invoke a DS2 package method expression as a function in a FedSQL SELECT statement. For more information, see "Using DS2 Packages in Expressions" in *SAS FedSQL Language Reference*.

For information about packages, see the "PACKAGE Statement" on page 1406 and "DS2 Packages" in *SAS DS2 Programmer's Guide*.

SYSTEM Expression

When a method and a function have identical names, the method call takes precedence over the function call. The function can then be invoked only by using a SYSTEM expression.

To invoke a SYSTEM expression, use this syntax:

SYSTEM.*function-expression*

A SYSTEM expression prepends a function expression with the dot notation, `system.`. For example, if SUM is the name of a method as well as the name of a function, the SUM function only can be invoked by using the SYSTEM expression: `system.sum(a,b,c)`.

THIS Expression

A THIS expression provides an alternate method to simultaneously declare and use a global scalar variable from anywhere within a DS2 program. A THIS expression is used to circumvent the standard variable lookup. In a THIS expression, DS2 searches for a scalar variable declaration of the identifier in global scope. If there is no such declaration, DS2 declares the identifier in global scope with DOUBLE type. Global variables can be referenced by all programming blocks in a DS2 program.

To invoke a THIS expression, use this syntax:

THIS.*variable-name*

A THIS expression prepends a variable with the dot notation, `THIS.`.

Note: DS2 stores `THIS.variable-name` only as *variable-name*. If you have a local variable with the same name as the global scalar variable and DS2 issues a diagnostic message about the variable, you will not be able to distinguish which variable is a problem. For example, if DS2 issues a warning message that **x** is not declared, you would not know whether the message refers to the global variable, **THIS.x**, or the local variable, **x**.

In the following example, the variable `s` becomes a global variable by using a THIS expression:

```
method init();
  this.s = sum(a,b,c,d,e);
end;
method run();
   t = put(this.s 5.4);
end;
```

The THIS expression provides a method to access a global variable that is hidden by a local variable with the same name. Here is an example.

```
proc ds2;
data;
   declare double x;    /* declare global x */

   method run();
      declare double x;  /* declare local x */

      /* Two variables exist with same name, "x". */
      /* Identifier "x" refers to local x in      */
      /* scope of run method.  Global x is hidden */
      /* by local x.                              */

      this.x = 1.0;    /* assign 1.0 to global x   */
      x = 0.0;         /* assign 0.0 to local x    */

      output;          /* global x with 1.0 output */
    end;
```

```
   enddata;
   run;
   quit;
```

SELECT Expression

Overview of the SELECT Expression

A SELECT expression is used to select between multiple expressions based on the values of other expressions.

To invoke a SELECT expression, use this syntax:

SELECT [(*select-expression*)]

WHEN (*when-expression*) [...WHEN (*when-expression*)] *result-expression*

[...WHEN (*when-expression*) [...WHEN (*when-expression*)] *result-expression*]

OTHERWISE [*default-result-expression*]

END

The SELECT expression evaluates each WHEN expression in order until a matching expression is found. Then the associated *result-expression* is evaluated as the result of the SELECT expression.

The SELECT expression can be used wherever any other expression can be used. Here is an example.

```
r = 25.5 + select (t) when (1) -a when (3) b*2 end;
```

SELECT Expression with a Selection Expression

If a selection expression is present, then it is evaluated. Then the WHEN expressions are evaluated in order. The result of the SELECT expression is the result expression of the first WHEN expression that evaluates to the same value as the selection expression. If all the WHEN expressions evaluate to different values than the selection expression, the result of the SELECT expression is the default result expression if present. Otherwise, it is a missing or null value. Here is an example.

```
s = select (t)
   when (1) x*10
   when (3) x
   when (5) x*100
   when (0) 0
   otherwise .
end;
```

If `t` is 5, then the SELECT expression evaluates to 'x*100'.

SELECT Expression without a Selection Expression

If a selection expression is not present, then the WHEN expressions are evaluated in order. The result of the SELECT expression is the result expression of the first WHEN expression that evaluates to true (a nonzero value). If all the WHEN expressions evaluate to false (zero), the result of the select expression is the default result expression if present. Otherwise, it is a missing or null value. Here is an example.

```
grade = select
  when (score >= 90) 'A'
  when (score >= 80) 'B'
  when (score >= 70) 'C'
  when (score >= 60) 'D'
  when (score >= 0 ) 'F'
end;
```

If **score** is 76, then the first *when-expression* to evaluate to true is **score>=70**. The *select-expression* evaluates to 'C'.

Optional Otherwise Expression

If an otherwise default result expression is not supplied, then DS2 provides a default result value to select when none of the WHEN expressions are selected. If the SELECT expression has type DOUBLE or CHAR in SAS mode, the default result value is a missing value (.). For all other data types in either mode, the default result value is NULL.

Result Expression with Multiple When Expressions

Multiple WHEN expressions can be associated with a single result expression. The WHEN expressions are listed consecutively followed by the single result expression. If any of the WHEN expressions associated with a result expression is the first matching WHEN expression, then the result of the SELECT expression is the result expression.

For example, the following SELECT expression evaluates to 'airplane' if the value of variable **t** is either 'A', 'a', 'P', or 'p'.

```
s = select (t)
   when ('A')
   when ('a')
   when ('P')
   when ('p') 'airplane'
   when ('C')
   when ('c') 'car'
   when ('T')
   when ('t') 'train'
```

```
   otherwise  'walk'
 end;
```

SELECT Expression Data Type

The type of a SELECT expression is determined by examining the type of the first result expression. If the first result expression is not a numeric data type, then the SELECT expression is assigned the type of the first result expression.

If the first result expression is a numeric data type, then all the result expressions are examined to find the widest numeric data type to assign as the type of the SELECT expression.

In the following example, **t** is a TINYINT, **b** is a BIGINT, **d** is a DECIMAL(10,5), and **s** is a CHAR(10). The select expression is assigned the type DECIMAL(10,5), the widest numeric type of TINYINT, BIGINT, DECIMAL(10,5), and CHAR(10).

```
r = select (t)
   when (1) t
   when (2) b
   when (3) d
   otherwise s
end;
```

Note: If **s** had been assigned to the first result expression, then the type of the SELECT expression would have been CHAR(10). If the first result expression has a non-numeric type, then the non-numeric type is assigned as the type of the SELECT expression.

Lazy Evaluation of the SELECT Expression

The SELECT expression uses lazy evaluation for the WHEN expressions. The WHEN expressions are evaluated in order until a matching WHEN expression is found or all when expressions are evaluated. If the SELECT expression has *n* WHEN expressions and the *i*th WHEN expression is selected, then only the first 1 to *i* WHEN expressions are evaluated. The *i*+1 to n when expressions are not evaluated.

Lazy evaluation also applies to the result expressions of the SELECT expression. The selected result expression is the only result expression evaluated.

In the following example, if `n[i]` equals 0, then only the first two WHEN expressions (`n[i] < 0` and `n[i] = 0`) are evaluated and only the second result expression `(y*10-r2)` is evaluated.

```
m(select
    when (n[i] < 0) y*100-r1
    when (n[i] = 0) y*10-r2
    when (n[i] > 0) y*10
 end);
```

Subscript Operator

The subscript operator enables you to access an element of a DS2 array or varlist.

The syntax for the subscript operation consists of an array or varlist identifier followed by an index expression for each dimension in the array or varlist. The syntax has the following form:

identifier \[*index-expression*[,...*index-expression*] \]

Note: Square brackets in syntax convention indicate optional syntax. The escape character (\) before a square bracket indicates that the square bracket is required for the syntax. Indexes in a subscript operator must be contained by square brackets ([ ]).

The data type of *index-expression* is INTEGER. If the specified *index-expression* is not an integer, it is coerced to INTEGER.

By default, indices are 1-based. A varlist has a lower bound of 1. An array has a lower bound of 1 if a lower bound is not specified in the DECLARE or VARARRAY statement. However, a different lower bound can be specified for an array. For example, the following arrays have a lower bound of -10 and an upper bound of 5. Thus, valid indices range from -10 to 5:

```
declare double ta[-10:5];
vararray double va[-10:5];
```

Examples of subscript operators are as follows:

```
a[i]
s[j * 2, k-3]
this.c[2, vwind, a[i]]
```

Each subscript operation accesses a single element of an array or varlist. For a multi-dimensional array, the subscript operation must specify an *index-expression* for each bound of the array, separated by a comma. For example, see the following log output:

```
80   proc ds2;
81   data _null_;
82     method init();
83       dcl double x[2,2];
84       dcl int i j;
85       x := (100 200 300 400);
86       do i = 1 to dim(x, 1);
87         do j = 1 to dim(x, 1);
88           put x[i,j]=;
89         end;
90       end;
91     end;
92   enddata;
93   run;
93 !      quit;
x[1,1]=100
x[1,2]=200
x[2,1]=300
x[2,2]=400
```

When an index expression is beyond the boundaries of the array or varlist, DS2 issues an error.

A subscript operation with an array can be used in any expression that accepts a scalar variable of the data type of the array. A subscript operation with a varlist can be used in any expression that accepts an element of a varlist. Currently, this is limited to the V* variable information functions.

Operators in Expressions

Operator Precedence in Compound Expressions

An operator symbolizes a type of operation that is to be performed on an operand, such as addition, comparison, and logical negation. When an expression contains multiple operators and operands, DS2 resolves the expression by using operator precedence. Operations are performed from the highest order of precedence to the lowest order of precedence.

The highest order of precedence is 1 and the lowest order of precedence is 9. Within a precedence level, with the exception of exponentiation, minimum, and maximum operators, operators associate from left to right. The exponentiation, minimum, and maximum operators associate from right to left.

By using the precedence order in Table A2.7 on page 2171, in the expression `5+a**b*3`, `a**b` is calculated first and then multiplied by `3`, and that result is added to `5`.

> **TIP** In DS2, x < y < z is evaluated like x < y and y < z.

The following table lists the operators and their order of precedence.

Table A22.7 *Operators and Their Order of Precedence in DS2 Compound Expressions*

Order of Precedence	Operator Name	Symbol	Associativity
1	Parenthesis	( )	left to right
1	Dot	.	left to right
1	Subscript	*identifier*[*index*]	left to right
1		SELECT expression	left to right
2		Unary + and –	right to left
2	Logical NOT	NOT or ^ or ~	left to right
2	Exponentiation, Maximum, Minimum	**, <>, ><	left to right
3	Multiplication, Division	*, /	left to right
4	Plus, Minus	+, –	left to right
5	Concatenation	|| or !!	left to right
5	Strip	..	left to right
6		IN, LIKE	left to right
7	Equality or Inequality	= or eq, ^= or ~=	right to left
7	Greater (or Less) Than Or Equal To, Greater (or Less) Than	>=, <=, >, < [1]	left to right
8	Logical AND	AND or &	left to right
9	Logical OR	OR, |, or !	left to right
10		IF expression	right to left

Order of Precedence	Operator Name	Symbol	Associativity
none	Variable Assignment	=	none
none	Array Assignment	:=	none
none	Unnamed Varlist	[*list-of-variable-names*]	none
none		_NEW_	none
none		OF	none
none		Method expression	none

1 In DS2, x < y < z is evaluated like x < y and y < z.

Expression Values by Operator

The following table shows the resolved value for expressions that are based on an operator:

Table A22.8 *Expression Values by Operator*

Operator	Value
Logical expressions[1]	
NOT or ^ or ~	If the operand is nonzero, the result is 0. If the operand is zero or missing, the result is 1. If the operand is null, the result is null.
OR or | or !	■ the logical OR of the two operands ■ null when one operand is zero or missing and the other operand is null ■ null when both operands are null ■ 1 when either operand is nonzero (even if the other operand is null or missing) ■ 0 when both operands are zero or missing
AND or &	■ the logical AND of the two operands ■ null when one operand is nonzero and the other operand is null

Operator	Value
	■ null when both operands are null ■ 1 when both operands are nonzero ■ 0 when either operand is zero or missing (even if the other operand is null)
Arithmetic expressions	
Unary plus	has the same value as the expression operand
Unary minus	is the arithmetic negation of the operand
+	the arithmetic sum of the operands
–	the arithmetic difference of the operands
*	the arithmetic product of the operands
/	the arithmetic quotient of the operands
**	the left operand raised to the power of the right operand
><	the minimum of the left and right operands
<>	the maximum of the left and right operands
any arithmetic operator	null when either or both operands are null
Relational expressions	
<	1 when the left operand is less than the right operand; otherwise, 0
>	1 when the left operand is greater than the right operand; otherwise, 0
<=	1 when the left operand is less than or equal to the right operand; otherwise, 0
>=	1 when the left operand is greater than or equal to the right operand; otherwise, 0
= or eq	1 when the left operand is equal to the right operand; otherwise, 0
^=	1 when the left operand is not equal to the right operand; otherwise, 0

Operator	Value
any logical operator	null when either or both operators are null
Concatenation expression	
|| or !![2]	the left operand merged with the right operand to form a new value
..	strips each argument before concatenating
IF expression	
IF	The value of the THEN expression if the logical expression is nonzero and non-null; otherwise, the value of the ELSE expression. For more information, see "IF Expression" on page 2150.
IN expression	
IN	1 when the comparison expression is contained in the constant list. For more information, see "IN Expression" on page 2152.
LIKE expression	
LIKE	1 when an expression matches a specified pattern; otherwise, 0 (zero). For more information, see "LIKE Expression" on page 2155.
SELECT expression	
SELECT	The value of the result expression of the first WHEN expression that matches the SELECT expression. For more information, see "SELECT Expression" on page 2166.
Other expressions	
.	Accesses a package attribute or calls a package method from code outside the package. For more information, see "DOT Operator Expression" on page 2148.
=	Assigns a value or an expression to a variable.
:=	Assigns values to an array.
identifier[*index-expression*]	Accesses an element of an array or varlist.
[*list-of-variable-names*]	Creates an unnamed varlist.

Operator	Value
NEW	Constructs an instance of a package. For more information, see "_NEW_ Operator" on page 1303.
OF	Transforms a variable list or variable array into a list of arguments for a function.
Method expression	Invokes a system method or a user-defined method. For more information, see "Getting Started with DS2 Methods" on page 48.

1 DS2 supports three truth values: TRUE, FALSE, and UNKNOWN. A nonzero operand maps to TRUE. A zero or missing operand maps to FALSE. A null operand maps to UNKNOWN.

2 The || concatenation operator does not remove any spaces. You can use the TRIM function to remove trailing spaces. However, the .. operator performs the same function as TRIM followed by concatenation. It is faster to use the .. operator (a .. b) than to use the TRIM function (TRIM(a) || TRIM(b)).

Short-Circuit Evaluation in DS2

In some cases, the value of a logical AND or OR expression can be determined without evaluating both operands. For example, if operand A is false, then the value of the expression (A AND B) is false regardless of the value of operand B. When the value of the entire logical expression can be determined based on the first operand alone, a programming language can "short-circuit" the evaluation and avoid the computational processing required to evaluate the second operand.

Short-circuit evaluation is available in DS2 by setting the option LOGICALEXPR=OPTIMIZED. The LOGICALEXPR= option is available as an argument in the DS2_OPTIONS statement, as a DS2 procedure option, and as a parameter on the DS2 runDS2 and runModel actions.

DS2 evaluates the operands in logical AND and OR expressions from left to right. When LOGICALEXPR=OPTIMIZED is enabled, DS2 evaluates the logical operators as follows:

- In the case of AND, if the first operand is zero or missing, the second operand is not evaluated, and the entire expression is false. If the first operand is nonzero or null, DS2 must evaluate the second operand.
- In the case of OR, if the first operand is nonzero, the second operand is not evaluated, and the entire expression is TRUE. If the first operand is zero, missing, or null, then DS2 must evaluate the second operand.

LOGICALEXPR=OPTIMIZED can be used to avoid performing mathematically invalid calculations. Consider the program that follows. In the program, the expression 1/sqrt(a) can be calculated only if a is nonnegative (due to the square root) and sqrt(a) is nonzero (due to the division). When LOGICALEXPR=OPTIMIZED is set, the program completes without an error because the second operand of the AND expression is not evaluated:

```
proc ds2 errorstop;
   ds2_options logicalexpr=optimized;
   data _null_;
      declare double a;
      method init();
         a=0;
         if (a>0 AND 1/sqrt(a) < .5) then
            put 'criteria satisfied';
         else
            put 'unacceptable value';
         put 'execution continues ...';
      end;
   enddata;
run; quit;
```

Lines similar to the following are written to the log:

```
unacceptable value
execution continues ...
NOTE: Execution succeeded. No rows affected.
```

LOGICALEXPR=OPTIMIZED can also be used to avoid performing calculations that are computationally expensive. Consider the following code snippet. The score method of the user-defined package credit_eval contains complex logic. For this business case, if the customer has already defaulted on a loan, then the invocation of that method should be avoided.

```
dcl package credit_eval ce;
reject_loan_request = (has_defaulted OR ce.score() < 500);
…
```

Short-circuit evaluation is provided for the AND and OR operators and their alternative operators “&”, “|”, and "!".

Appendix 3

DS2 Example Programs

Example: Find Minimums

Example Overview: Find Minimums

This example demonstrates how to use the three system-defined methods, INIT, RUN, and TERM.

A DS2 program executes in the following sequence:

1. Any global variables are declared.
2. The INIT method is called. INIT is typically used for variable initialization.
3. The RUN method is called. The RUN method is where the implicit loop exists. RUN executes until all input tables are completely read.
4. The TERM method is called. Final processing is performed.

The following program demonstrates this flow of control by finding the minimum values in a table. In this program, the INIT method initializes the variables used to find the current minimum, the RUN method compares input values with the current minimum, and the TERM method writes the minimums to an output table.

Example Code: Find Minimums

```
proc ds2;
/* Create table to work with in this example */
data xy_data;
   dcl double x y;
   method init();
      do x = 1 to 5;
         y = 2*x;
         output;
      end;
   end;
enddata;
run;
/* Find the minimum value for x and y */
data xy_mins;
   dcl double min_x min_y;
   retain min_x min_y;
   keep min_x min_y;

   method init();
      min_x = 999999;
      min_y = 999999;
   end;

   method run();
      set xy_data;
      if x < min_x then min_x = x;
      if y < min_y then min_y = y;
   end;

   method term();
      output;
   end;
enddata;
run;
/* Send result table of minimums to the PROC for output */
data;
   method run();
      set xy_mins;
   end;
enddata;
run;
quit;
```

Example Output: Find Minimums

The SAS System

MIN_X	MIN_Y
1	2

Example: SQL in a DS2 Program

Example Overview: SQL in a DS2 Program

This example illustrates how to use a SQL statement in a DS2 program. To access the output from a SQL query, put the query in a SET statement. When the SET statement runs, it sequentially reads the rows that are returned by the query.

Example Code: SQL in a DS2 Program

In this example, the first DS2 program calculates annual balances for an account into which contributions of $2000 are made every year from 2004 to 2014. The account carries a 7% interest rate, compounded annually. The second program generates the table. The third program writes the results of a SQL query. The query selects all rows from INVESTMENT where the value of INVESTMENT_YEAR is greater than 2010.

```
proc ds2;
data investment;
   dcl integer investment_year;
   dcl double capital;
   method init();
      capital = 0;
      do investment_year = 2004 to 2014;
         capital = capital + (2000 + .07 * (capital+2000));
         output;
      end;
   end;
enddata;
run;
```

```
data;
   method run();
      set investment;
   end;
enddata;
run;
data;
   method run();
      set {select * from investment where investment_year > 2010};
   end;
enddata;
run;
quit;
```

Example Output: SQL in a DS2 Program

The SAS System

INVESTMENT_YEAR	CAPITAL
2004	2140
2005	4429.8
2006	6879.886
2007	9501.478

Example: Make Two New Tables Based on a Condition

Example Overview: Make Two New Tables Based on a Condition

This example illustrates how to create tables based on a condition. Programs 1 and 2 create two tables, DEPT1_ITEMS and DEPT2_ITEMS, that hold costs for items used by two departments. The third program creates two tables, HIGHCOSTS and LOWCOSTS, based on the costs of the items in the two items tables. Programs 4 and 5 output the contents of the costs tables.

Example Code: Make Two New Tables Based on a Condition

```
proc ds2;
/* Program 1 */
data dept1_items (overwrite=yes);
   dcl varchar(20) item;
   dcl double cost;
   method init();
      item = 'staples';   cost =  1.59; output;
      item = 'pens';      cost =  3.26; output;
      item = 'envelopes'; cost = 11.42; output;
   end;
enddata;
run;
/* Program 2 */
data dept2_items (overwrite=yes);
   dcl varchar(20) item;
   dcl double cost;
   method init();
      item = 'erasers'; cost =  5.43; output;
      item = 'paper';   cost = 26.92; output;
      item = 'toner';   cost = 62.29; output;
   end;
enddata;
run;
/* Program 3 */
```

```
data lowCosts (overwrite=yes) highCosts (overwrite=yes);
   method run();
      set dept1_items dept2_items;
      if cost <= 10.00 then
         output lowCosts;
      else
         output highCosts;
      end;
enddata;
run;
/* Program 4 */
data;
   method run();
      set lowCosts;
   end;
enddata;
run;
/* Program 5 */
data;
   method run();
       set highCosts;
   end;
enddata;
run;
quit;
```

Example Output: Make Two New Tables Based on a Condition

The SAS System

ITEM	COST
staples	1.59
pens	3.26
erasers	5.43

The SAS System

ITEM	COST
envelopes	11.42
paper	26.92
toner	62.29

Example: Change Case of Text Output

Example Overview: Change Case of Text Output

The code in this example reads the two tables created in the previous example, DEPT1_COSTS and DEPT2_COSTS, and writes rows with values in the COST column of less than or equal to $10 in lowercase, and values greater than $10 in uppercase.

Example Code: Change Case of Text Output

```
proc ds2;
data;
   method run();
      set dept1_items dept2_items;
         if cost <= 10.00 then
            item = lowcase(item);
         else
            item = upcase(item);
         end;
enddata;
run;
quit;
```

Example Output: Change Case of Text Output

The SAS System

ITEM	COST
staples	1.59
pens	3.26
ENVELOPES	11.42
erasers	5.43
PAPER	26.92
TONER	62.29

Example: Scope

Example Overview: Scope

This example shows the use of CHAR and VARCHAR types and their operators and functions. Also, in this example, the variables A, B, and C are locally scoped to the INIT method. That is, their value is not seen outside of the INIT method and is not written to the result table.

Example Code: Scope

```
proc ds2;
data;
  dcl char(24) abc abc2;
  method init();
    dcl char(8) a b c;

    a = repeat('a',5);
    b = repeat('b',6);
    c = repeat('c',7);

    abc = a || b || c;
    abc2 = trim(a) || trim(b) || c;
  end;
enddata;
run;
data;
  dcl char(24) abc abc2;
  method init();
    dcl varchar(8) a b c;

    a = repeat('a',5);
    b = repeat('b',6);
    c = repeat('c',7);

    abc = a || b || c;
    abc2 = trim(a) || trim(b) || c;
  end;
enddata;
run;
quit;
```

Example Output: Scope

The SAS System

abc	abc2
aaaaaa bbbbbbb cccccccc	aaaaaabbbbbbbccccccccc

The SAS System

abc	abc2
aaaaaabbbbbbbccccccccc	aaaaaabbbbbbbccccccccc

Example: Functions

Example Overview: Functions

This example shows how to use a function in DS2. The code computes the number of bits required to store an integer.

Example Code: Functions

```
proc ds2;
data;
   dcl integer i bits;
   method init();
      do i = 1 to 1000 by 100;
         bits = ceil(log(i) / log(2));
         output;
      end;
   end;
enddata;
run;
```

```
quit;
```

Example Output: Functions

The SAS System

i	bits
1	0
101	7
201	8
301	9
401	9
501	9
601	10
701	10
801	10
901	10

Example: Arrays

Example Overview: Arrays

The first program illustrates basic array procedures. In the final section, elements of dblNegSubArray are specified by using numeric expressions inside the array brackets. Expressions that resolve to a number that falls out of the bounds of the declared size of the array give an error message.

The second program gives several examples of array assignments. When an array is assigned, data types that do not match the type of the target array are converted to the target array type.

Note that if you add an equal sign after a variable or array element in a PUT statement, then the output is preceded by the variable or array element name and an equal sign.

Note: The DS2 procedure option SCOND=NONE is set in this example to suppress log messages that are generated by DS2 variable strict mode.

Example Code: Arrays

```
proc ds2 scond=none;
/* Basic Arrays */
data _null_;
   dcl char(10)  strArray[4] str;
   dcl double    dblArray[3];
   dcl int       intArray[10];
   dcl double    dblNegSubArray[-4:-1];
   dcl int x;
   method init();
      put 'BASIC ARRAYS';
      strArray[1] = 'abc';
      strArray[2] = 'def';
      strArray[3] = 'ghi';
      strArray[4] = 'jkl';
      put strArray[1]= ;
      put strArray[2]= ;
      put strArray[3]= ;
      put strArray[4]= ;
      put;

      str = strArray[1];
      put str=;
      put;

      dblArray[1] = 3;

Example: SELECT Statement

Example Overview: SELECT Statement

This example illustrates the SELECT statement. In this example, a DO loop encloses a SELECT statement. The SELECT statement reads the current value of the loop counter I and writes a character when the WHEN statement is true. The REPEAT statement repeatedly prints the character based on the value of the loop counter.

Example Code: SELECT Statement

```
proc ds2;
data;
   dcl char(10) s;
   method run();
      dcl char(1) x;
      dcl int i;
      do i=1 to 10;
         select(i);
            when(1) x='A';
            when(2) x='B';
            when(3) x='C';
            when(4) x='D';
            when(5) x='E';
            when(6) x='F';
            when(7) x='G';
            when(8) x='H';
            when(9) x='I';
            otherwise x='J';
         end;
         s=repeat(x,i);
         output;
      end;
   end;
enddata;
run;
quit;
```

Example Output: SELECT Statement

Example: GOTO and LEAVE Statements with Labels

Example Overview: GOTO and LEAVE Statements with Labels

This example presents three programs that show branching. The first uses GOTO to branch to a label. The second uses LEAVE without a label, and the third uses LEAVE with a label. For more information, see “GOTO Statement” on page 1374 and “LEAVE Statement” on page 1382.

Example Code: GOTO and LEAVE Statements with Labels

```
proc ds2;
data;
   dcl double i j;
   method init();
      i = 1;
   head:
      j = 2*i;
      i = i+1;
      if i < 10 then do;
         output;
         goto head;
      end;
   end;
enddata;
run;
data _null_;
   dcl int x y;
   method init();
      put 'loop test 1';
      x = 1;
      y = 2;
      if (x ~= -5) then
         do i = 1 to 10;
            put i;
            if i > 4 then leave;
         end;
      else
          put 'else';
   end;
enddata;
run;
data _null_;
   dcl int g;
   method init();
      put 'label test 1';
      x = 1;
      y = 2;
      if (x > -5) then
         lab:
         do i = 1 to 10;
            do j = 1 to 5;
               put i j;
               if i > 4 then leave lab;
            end;
         end;
      else
         do;
```

```
            put 'else';
         end;
   end;
enddata;
run;
quit;
```

Example Output: GOTO and LEAVE Statements with Labels

The following output is the result of using GOTO to branch to a label.

The SAS System

i	j

4 4
4 5
5 1
```

Example: Overloaded Methods

Example Overview: Overloaded Methods

This example illustrates how to set up overloaded methods. For more information about methods, see the "METHOD Statement" on page 1391.

Example Code: Overloaded Methods

```
proc ds2;
data _null_;
   method concat(nvarchar(200) x, nvarchar(200) y) returns nvarchar(400);
      return x || y;
   end;

   method concat(nvarchar(200) x, nvarchar(200) y, nvarchar(200) z)
      returns nvarchar(600);
      return x || y || z;
   end;

   method run();
      y = concat(n'abc', n'def');
      put 'y= ' y;
      y = concat(n'abc', n'def', n'ghi');
```

```
      put 'y= ' y;
   end;
enddata;
run;
data _null_;
   method d() returns double;
      return 99;
   end;

   method d(double x, double y, double z) returns double;
      return x + y + z;
   end;

   method d(int x, int y, int z) returns int;
      return x + y + z + 500;
   end;

   method run();
      dcl double d;
      d = d(1,2,3);
      put 'd= ' d;
      d = d(100.1, 100.2, 100.3);
      put 'd= ' d;
   end;
enddata;
run;
quit;
```

Example Output: Overloaded Methods

The following lines are written to the SAS log.

```
y=  abcdef
y=  abcdefghi

d=  506
d=  300.6
```

Example: Analyze a Table Using Multiple Threads

Example Overview: Analyze a Table Using Multiple Threads

This example shows the creation of a table that is then analyzed using multiple threads.

Example Code: Analyze a Table Using Multiple Threads

```
libname spde spde 'c:\temp\spde';

run;
quit;

proc print data=class_counts; run;
```

Example Output: Using Four Threads to Compute Summary Statistics

The following lines are written to the SAS log. Note that every time you run the program, the log output is different.

```
id=2 cnt=1 sum_age=0 cnt_male=0 cnt_female=0
id=0 cnt=1404506 sum_age=18702097 cnt_male=739215 cnt_female=665290
id=3 cnt=1 sum_age=0 cnt_male=0 cnt_female=0
id=1 cnt=495496 sum_age=6597903 cnt_male=260785 cnt_female=234710
```

The following table is generated.

Obs	avg_age	tot_male	tot_female
1	13.3158	1000000	900000

Example: Data Cleaning

Example Overview: Data Cleaning

Sometimes, due to input error, data values might have leading and trailing blanks. Unless you specifically filter for this possibility, joins and similar database operations that depend on identically formatted data values will not perform correctly. Another problem that can occur is unintentional duplication of records (that is, multiple records (rows) with the same key). This example shows programs that remove blanks from data values, and list duplicate rows for potential deletion.

The first DS2 program creates a simple data table, EMPLOYEES1, that contains duplicate rows and string values. Some of the rows contain blanks.

The second program uses the STRIP function to remove leading and trailing blanks from values in the EMP column. The table is written to EMPLOYEES2.

The third program uses an embedded SQL SELECT statement to display the duplicates. You can use this output to determine which records should be deleted. Note that this program would have not generated correct output if you did not first remove the blanks from the data values, because the SELECT statement would not have grouped the data accurately.

Example Code: Data Cleaning

```
proc ds2;
data employees1 (overwrite=yes);
   dcl double id;
   dcl char emp;
   method init();
      id =  60918 ; emp = 'user1'; output;
      id =  60919 ; emp = ' user2'; output;
      id =  60920 ; emp = ' user3'; output;
      id =  60918 ; emp = 'user1'; output;
      id =  60922 ; emp = 'user4'; output;
      id =  60925 ; emp = ' user5 '; output;
      id =  60926 ; emp = 'user6'; output;
      id =  60919 ; emp = 'user2'; output;
      id =  60928 ; emp = ' user7'; output;
      id =  60918 ; emp = 'user1'; output;
   end;
enddata;
run;
data employees2 (overwrite=yes);

   method run();
      set employees1;
      emp = strip(emp);
   end;
enddata;
run;
data ;
   method run();
      set {select id as dupid,  count(id) as dups
         from  employees2
         group by id
         having count(id) > 1};

   end;
enddata;
run;
quit;
```

Example Output: Data Cleaning

The SAS System

DUPID	DUPS
60918	3
60919	2

Example: SUBSTR Function

Example Overview: SUBSTR Function

The example shows how to use the SUBSTR function. SUBSTR is used to convert the word CAT to DOG by changing one character at a time.

Example Code: SUBSTR Function

```
proc ds2;
data _null_;
   dcl char(3) a b;
   method init();
      a = 'cat';
      put 'a=' a;

      substr(a,2,1) = 'o';
      put 'a=' a;

      substr(a,1,1) = 'd';
      put 'a=' a;

      substr(a,3,1) = 'g';
      put 'a=' a;
      b = a;
   end;
enddata;
run;
```

Example Output: SUBSTR Function

The following lines are written to the SAS log.

```
a= cat
a= cot
a= dot
a= dog
```

Example: PUT with SAS Formats

Example Overview: PUT with SAS Formats

This example illustrates how to use SAS formats with the PUT statement.

Example Code: PUT with SAS Formats

```
proc ds2;
data _null_;
   method init();
      dcl double d;
      dcl int i;
      dcl char(32) x;

      d = 99;
      x = put(d, best12.6);
      put 'x=' x;

      d = 100;
      x = put(d, best.);
      put 'x=' x;

      i = 10847;
      x = put(i, mmddyy8.);
      put 'x=' x;

      c = 'abc';
      x = put(c, $char8.);
      put 'x=' x;
```

```
   end;
enddata;
run;
quit;
```

Example Output: PUT with SAS Formats

The following lines are written to the SAS log.

```
x=           99
x=          100
x= 09/12/89
x= abc
```

Example: Generate Statistics from Table Data

Example Overview: Generate Statistics from Table Data

This example analyzes the price movement of a simulated stock table. The first DS2 program creates the stock price table. There are two weeks of the open, high, low, and close prices for the stock.

The second program performs the analysis. A 2–day moving average of closing prices is created by assigning the previous two days' closing prices to elements of the CY array, averaging them by using the MEAN function, and then sending them to output as C_MA. The INIT method initializes the array CY and C_MA variables to the first price in the STOCK table. The RUN method assigns values to the array as it loops through the table.

The CTR variable is incremented each time through the RUN method. The moving average is not valid until two days of prices have been averaged, so the output begins with the third record (that is, when CTR > 2). After a row has been written, the CY array is updated.

The following statistics are also calculated:

- the daily change in closing price, **Chng**, calculated by subtracting yesterday's close, CY[1], from today's close
- the change from open to the closing price, O_C

- the range of the day's prices, H_L, calculated by subtracting the low price from the high price

Example Code: Generate Statistics from Table Data

```
proc ds2;
data stock (overwrite=yes);
   dcl date d;
   dcl double o h l c;
   method init();
      d = date '2010-09-18' ; o =  20; h = 22.25; l = 18; c = 21.5; output;
      d = date '2010-09-19' ; o =  21; h = 23.5; l = 19.25; c = 22; output;
      d = date '2010-09-20' ; o =  22.25; h = 24.75; l = 20; c = 21; output;
      d = date '2010-09-21' ; o =  21; h = 21.5; l = 18.75; c = 19; output;
      d = date '2010-09-22' ; o =  18; h = 19; l = 17.25; c = 17; output;
      d = date '2010-09-25' ; o =  17; h = 18; l = 15.5; c = 17; output;
      d = date '2010-09-26' ; o =  17.5; h = 20; l = 16; c = 18; output;
      d = date '2010-09-27' ; o =  18.5; h = 21; l = 18; c = 20; output;
      d = date '2010-09-28' ; o =  20; h = 22.25; l = 19.5; c = 21; output;
      d = date '2010-09-29' ; o =  21; h = 23; l = 18.75; c = 21.5; output;
   end;
enddata;
run;
data;
   keep d o h l c Chng O_C H_L C_MA;
   dcl double cy[2] C_MA H_L Chng O_C;
   dcl int ctr;
   method init();

Example: Matrices and Non-linear Equations

Example Overview: Matrices and Non-linear Equations

This example solves a system of non-linear equations using Newton's iterative process.

In this example, the root (to within a given epsilon) is found after five iterations of the loop, and is equal to (.5, 0, –.5236). Zero appears as an extremely small number.

One interesting feature to note in Newton's example is how the result matrix can be reused. In a simple method calculation, `r=m.mult(m2);` the result matrix instance is automatically created. However, if the result instance already exists, and its size is correct, the method reuses the result matrix for efficiency purposes. Note how this is done in Newton's computation loop. When the matrix is created the first time, the

left side result is reused in computations such as `ji=jm.inverse();`. Otherwise, you would have to free the old matrix and allocate a new one each time.

Example Code: Matrices and Non-linear Equations

```
proc ds2;
/*
 * Solve the system of equations
 *
 *   3*x1 + cos(x2*x3) - .5                = 0
 *   x1^2 - 81(x2 + .1)^2 + sin(x3) + 1.06 = 0
 *   e^(-x1*x2) + 20*x3 + (10pi-3)/3       = 0
 *
 * using Newton's method:
 *
 *   X_m = X_m0 - J^-1(X_m0) * F(X_m0)
 *

Example: Use the SQLSTMT Package in Another Package

Example Overview: Use the SQLSTMT Package in Another Package

This example shows how to use an instance of a package SQLSTMT in another package. It also shows the use of the _NEW_ operator to delay construction of the SQLSTMT instance until after the creation of the table that is referenced by the FedSQL statement. If the SQLSTMT instance was constructed before the referenced table was created, then the prepare of the FedSQL statement fails in the constructor.

Example Code: Use the SQLSTMT Package in Another Package

```
package fibonnaci;
   declare int nMax;    /* maximum index in this series */
```

```
   method fibonnaci(int n);
      nMax = n;
   end;

   method output(char(100) tablename);
      declare int    n;    /* index of fib in Fibonacci series */
      declare double fib;  /* Fibonacci number */

      declare package sqlstmt stmt;
      /* note that stmt is not created */

      sqlexec('create table ' || tablename || '
         (n int, fib double)');

      /* Using _new_ allows delay of prepare of SQL statement until
after */
      /* output table is created */

      stmt = _new_ sqlstmt('insert into ' || tablename || '
         values (?, ?)');

      /* fibonnaci(0) = 0 */
      stmt.setInteger(1, 0);     /* column n */
      stmt.setDouble(2, 0);      /* column fib */
      stmt.execute();

      /* fibonnaci(1) = 1 */
      stmt.setInteger(1, 1);     /* column n */
      stmt.setDouble(2, 2);      /* column fib */
      stmt.execute();

      first = 0;
      second = 1;

      do n = 2 to nMax;
         fib = first + second;
         stmt.setInteger(1, n);
         stmt.setDouble(2, fib);
         stmt.execute();

         first = second;
         second = fib;
      end;
   end;
endpackage;
```

The following code block creates an instance of package FIBONACCI, and the Fibonacci instance is used to generate an output table of a Fibonacci series.

```
data _null_;
   method init();
      declare package fibonnaci fibseries(20);
      fibseries.output('fibdata');
   end;
enddata;
run;
```

Example: Update the Values of a Table by Using Two Databases

Example Overview: Update the Values of a Table By Using Two Databases

The following example illustrates how the SQLSTMT package can facilitate updating a table in one database based on the values in another table in a second database. In the example program, stmt1 queries for all the x and y columns from the ORACLE table db1.dataset1. Then for each rowset in the result set from db1.dataset1, stmt2 finds the rows in BASE table db2.dataset2 that have the same x column values as the x value read from db1.dataset1. Stmt2 then updates the BASE table db2.dataset2 y column values of the found rows to be the same as the y value read from db1.dataset1.

Example Code: Update the Values of a Table By Using Two Databases

```
libname db1 odbc user=XXXX pw=XXXX dsn=exadat;
libname db2 './base';

proc ds2;
data _null_;
   declare double x y;
   method run();
      dcl package sqlstmt stmt1('select x,y from db1.dataset1');
      dcl package sqlstmt stmt2('update db2.dataset2 set y=? where
x=?',
          [y x]);

      stmt1.execute();
      stmt1.bindResults([x y]);
      do while (stmt1.fetch() = 0);
         stmt2.execute();
      end;
   end;
enddata;
run;
quit;
```

Example: Store FedSQL Statements in a Hash Package

Example Overview: Store FedSQL Statements in a Hash Instance

The following example shows how to use a hash package to manage a set of FedSQL statements. A set of FedSQL statements is dynamically allocated and stored in a hash package. The hash package is indexed by an integer key that is used to retrieve the appropriate FedSQL statement from the hash package.

Example Code: Store FedSQL Statements in a Hash Package

```
proc ds2;
/* Create 5 tables testdata1...testdata5.
 * Each table has 3 double columns (x,y,z) and no rows. */
data _null_;
   method init();
      declare int i;
      declare int rc;

      do i = 1 to 5;
         rc = sqlexec('create table testdata' || i ||
            '(x double, y double, z double)');
         if (rc ne 0) then put 'TEST FAILED';
      end;
   end;
enddata;
run;
quit;

proc ds2;
data _null_;

   /* Create an SQLstmt reference.
    * Note: does NOT create an sqlstmt instance. */
   declare package sqlstmt s;
   /* Create a hash instance. */
   declare package hash h();
```

```
/* Hash key: sqlstmts are accessed by index 1..5. */
declare int  i;
/* Variables to bind to sqlstmt parameters. */
declare double u v w;

/* Create 5 sqlstmts to insert data in tables
 * testdata1...testdata5. Store the sqlstmts in hash
 * table h. */

method init();
   declare int rc;

   h.definekey('i');    /* Key is index 1..5. */
   h.definedata('s');   /* Data is an sqlstmt reference. */
   h.definedone();

   /* Dynamically create 5 sqlstmt instances and add
    * each sqlstmt to hash table. */
   do i = 1 to 5;

      /* Dynamcially create an sqlstmt.
       * Variables [u v w] are bound to the parameters of
       *the sqlstmt. */
      s = _new_ sqlstmt('insert into testdata'
         || i || ' values (?,?,?)', [u v w]);

      /* Add the sqlstmt to hash h with key i. */
      rc = h.add();
      if (rc ne 0) then put 'TEST FAILED';
    end;
 end;

/* Retrieve the sqlstmts from the hash table and execute
 * the sqlstmts to insert rows in the tables. */

method run();
   declare int j;
   declare int rc;

   /* For each of 5 data tables testdata1...testdata5, */
   /* insert 9 rows. */
   do j = 1 to 9;
      do i = 1 to 5;

         /* Find the sqlstmt in hash by index i. */
         rc = h.find();
         if (rc ne 0) then put 'TEST FAILED';

         /* Set values to insert into the table testdata i. */
         u = i;        /* data for 1st column (x) */
         v = -j;       /* data for 2nd column (y) */
         w = i*10+j;   /* data for 3rd column (z) */
```

```
            /* Execute the sqlstmt to insert the row. */
            rc = s.execute();
            if (rc ne 0) then put 'TEST FAILED';

            /* Explicitly close the result set to free resources.
             * If not explicitly closed, result set would be
             * automatically closed at next execute of the sqlstmt. */
            rc = s.closeResults();
            if (rc ne 0) then put 'TEST FAILED';

         end;
      end;
   end;

   /* Explicitly delete each sqlstmt instance.  Note if not
    * explicitly deleted, the sqlstmt instances would automatically
    * be deleted when the sqlstmt variables referencing the instances
    * were deleted. */

   method term();
      declare int rc;

      do i = 1 to 5;
         rc = h.find();
         if (rc ne 0) then put 'TEST FAILED';
         s.delete();
      end;
   end;
enddata;
run;

Example: Filter Trailing Spaces from MySQL 8 CHAR() Data

Example Overview: Filtering Trailing Spaces from MySQL 8 CHAR() Data

DS2 uses ANSI SQL rules for handling trailing spaces in CHAR() values. MySQL 8 treats trailing spaces as significant values by default. This difference interferes with character comparisons that are performed when using FedSQL statements in DS2. This example shows how the TRIM function can be used to trim trailing spaces in a SQLSTMT package instance. The package instance filters character values from two tables while creating a third, temporary table that contains values common to both tables.

Note: This task is not necessary if you change MySQL 8 to use a collation for comparisons that follows ANSI SQL rules for handling trailing spaces.

Example Code: Filtering Trailing Spaces from MySQL 8 CHAR() Data

```
/* Assign a libref to a MySQL 8 server */
libname mylib mysql server=sql8svr user=myuserid pw=mypwd db=database1;

/* Create two tables, Class and Names, in the database. In table
Class, create two columns
called Name1 and ID and specify values for 5 rows. */
proc ds2;
data mylib.class (overwrite=yes);
 dcl char(8) name1;
 dcl char(30) id;
 method init();
 name1='JAMES'; id='10000000000000000000000000000000'; output;
 name1='GEORGE '; id='98765432109876543210987654321 0'; output;
 name1='JANET'; id='33'; output;
 name1='PAUL';id='44'; output;
 name1='JOHN'; id='12345678901234567890123456789 0'; output;
 end;
 enddata;
```

```
 run;

/* In table Names, create one column called Name that has four rows.
Include values from the Name1 column in table Class in the rows. */
data mylib.names (overwrite=yes);
 dcl char(8) name;
 method init();
 name='GEORGE  '; output;
 name='PAUL '; output;
 name='JOHN '; output;
 name='Ringo'; output;
 end;
 enddata;
run;
quit;

/* Create a temporary table that includes an ID column and defines
an instance of the SQLSMT package that submits a FedSQL SELECT
statement
to retrieve the ID and Name1 values from table Class. Include a WHERE
clause
that compares values in the Name1 column to trimmed instances of
variable ?.
Specify a Name column as a constructor argument.  */
proc ds2;
data _null_;
