### PART 2 SAS Windowing Environment 155

**Chapter 9 / Working in the SAS Windowing Environment** 157

- Definition of the SAS Windowing Environment 158
- Description of SAS in the X Environment 159
- The SAS Session Manager (motifxsassm) in UNIX 161
- Displaying Function Key Definitions in UNIX Environments 165
- The SAS ToolBox in UNIX Environments 167
- Opening Files in UNIX Environments 170
- Changing Your Working Directory in UNIX Environments 173
- Selecting (Marking) Text in UNIX Environments 174
- Copying or Cutting and Pasting Selected Text in UNIX Environments 177
- Using Drag and Drop in UNIX Environments 178
- Searching for and Replacing Text Strings in UNIX Environments 179
- Sending Mail from within Your SAS Session in UNIX Environments 180
- Configuring SAS for Host Editor Support in UNIX Environments 183
- Getting Help in UNIX Environments 184

### PART 3 Data Considerations 241

**Chapter 11 / Data Representation** 243

- Numeric Variable Length and Precision in UNIX Environments 243
- Missing Values in UNIX Environments 244
- Reading and Writing Binary Data in UNIX Environments 244
- Converting a UNIX Datetime Value to a SAS Datetime Value 245
PART 4  Host-Specific Features of the SAS Language  247

Chapter 12 / Commands under UNIX  249
  SAS Commands under UNIX  250
  Dictionary  250

Chapter 13 / Data Set Options under UNIX  275
  SAS Data Set Options under UNIX  275
  Summary of SAS Data Set Options in UNIX Environments  276
  Dictionary  279

Chapter 14 / Environment Variables under UNIX  285
  Defining Environment Variables in UNIX Environments  285
  Dictionary  287

Chapter 15 / Formats under UNIX  291
  SAS Formats under UNIX  291
  Dictionary  291

Chapter 16 / Functions and CALL Routines under UNIX  299
  SAS Functions and CALL Routines under UNIX  299
  Dictionary  300

Chapter 17 / Informats under UNIX  327
  SAS Informats under UNIX  327
  Dictionary  327

Chapter 18 / Macro Facility under UNIX  335
  About the Macro Facility under UNIX  335
  Automatic Macro Variables in UNIX Environments  335
  Macro Statements in UNIX Environments  337
  Macro Functions in UNIX Environments  337
  SAS System Options Used by the Macro Facility in UNIX Environments  338
  Using Autocall Libraries in UNIX Environments  338

Chapter 19 / Statements under UNIX  341
  SAS Statements under UNIX  341
  Dictionary  341

Chapter 20 / System Options under UNIX  375
  SAS System Options under UNIX  376
  Determining How a SAS System Option Was Set  377
  Restricted System Options  378
  Dictionary  379

PART 5  Procedures under UNIX  467

Chapter 21 / Overview  469
  SAS Procedures under UNIX  469
Appendix 1 / The !SASROOT Directory .................................................. 521
  Introduction to the !SASROOT Directory ........................................ 521
  Contents of the !SASROOT Directory ............................................. 521

Appendix 2 / Tools for the System Administrator ................................. 527
  The Utilities Directory in UNIX Environments .................................. 527
  Installing Manual Pages ................................................................... 528
  Utilities in the /utilities/bin Directory .......................................... 528

  About EBCDIC and ASCII Data ....................................................... 587
  Moving Data from EBCDIC to ASCII Systems .................................. 590
  Moving Data from ASCII to EBCDIC Systems ................................... 597
About This Book

Syntax Conventions for the SAS Language

Overview of Syntax Conventions for the SAS Language

SAS uses standard conventions in the documentation of syntax for SAS language elements. These conventions enable you to easily identify the components of SAS syntax. The conventions can be divided into these parts:

- syntax components
- style conventions
- special characters
- references to SAS libraries and external files

Syntax Components

The components of the syntax for most language elements include a keyword and arguments. For some language elements, only a keyword is necessary. For other language elements, the keyword is followed by an equal sign (=). The syntax for arguments has multiple forms in order to demonstrate the syntax of multiple arguments, with and without punctuation.

**keyword**

specifies the name of the SAS language element that you use when you write your program. Keyword is a literal that is usually the first word in the syntax. In a CALL routine, the first two words are keywords.

In these examples of SAS syntax, the keywords are bold:

- **CHAR** (*string, position*)
- **CALL RANBIN** (*seed, n, p, x*)
- **ALTER** (*alter-password*)
BEST w.
REMOVE <data-set-name>

In this example, the first two words of the CALL routine are the keywords:

CALL RANBIN( seed, n, p, x )

The syntax of some SAS statements consists of a single keyword without arguments:

DO;
... SAS code ...
END;

Some system options require that one of two keyword values be specified:

DUPLEX | NODUPEX

Some procedure statements have multiple keywords throughout the statement syntax:

CREATE <UNIQUE> INDEX index-name ON table-name ( column-1 <, column-2, ... > )

argument

specifies a numeric or character constant, variable, or expression. Arguments follow the keyword or an equal sign after the keyword. The arguments are used by SAS to process the language element. Arguments can be required or optional. In the syntax, optional arguments are enclosed in angle brackets ( < > ).

In this example, string and position follow the keyword CHAR. These arguments are required arguments for the CHAR function:

CHAR ( string, position )

Each argument has a value. In this example of SAS code, the argument string has a value of 'summer', and the argument position has a value of 4:

x=char('summer', 4);

In this example, string and substring are required arguments, whereas modifiers and startpos are optional.

FIND(string, substring <, modifiers> <, startpos>

argument(s)

specifies that one argument is required and that multiple arguments are allowed. Separate arguments with a space. Punctuation, such as a comma ( , ) is not required between arguments.

The MISSING statement is an example of this form of multiple arguments:

MISSING character(s);

<LITERAL_ARGUMENT> argument-1 <<LITERAL_ARGUMENT> argument-2 ... >

specifies that one argument is required and that a literal argument can be associated with the argument. You can specify multiple literals and argument pairs. No punctuation is required between the literal and argument pairs. The ellipsis (...) indicates that additional literals and arguments are allowed.

The BY statement is an example of this argument:

BY <DESCENDING> variable-1 <<DESCENDING> variable-2 ...>;
argument-1 <options> <argument-2 <options> ...

specifies that one argument is required and that one or more options can be
associated with the argument. You can specify multiple arguments and
associated options. No punctuation is required between the argument and the
option. The ellipsis (...) indicates that additional arguments with an associated
option are allowed.

The FORMAT procedure PICTURE statement is an example of this form of
multiple arguments:

    PICTURE name <(format-options)>
    <value-range-set-1 <(picture-1-options)>
    <value-range-set-2 <(picture-2-options) >...>;

argument-1=value-1 <argument-2=value-2 ...

specifies that the argument must be assigned a value and that you can specify
multiple arguments. The ellipsis (...) indicates that additional arguments are
allowed. No punctuation is required between arguments.

The LABEL statement is an example of this form of multiple arguments:

    LABEL variable-1=label-1 <variable-2=label-2 ...>;

argument-1 <, argument-2, ...

specifies that one argument is required and that you can specify multiple
arguments that are separated by a comma or other punctuation. The ellipsis (...) indicates a continuation of the arguments, separated by a comma. Both forms
are used in the SAS documentation.

Here are examples of this form of multiple arguments:

    AUTHPROVIDERDOMAIN (provider-1:domain-1 <, provider-2:domain-2, ...
    INTO :macro-variable-specification-1 < , :macro-variable-specification-2, ...

Note: In most cases, example code in SAS documentation is written in lowercase
with a monospace font. You can use uppercase, lowercase, or mixed case in the
code that you write.

Style Conventions

Style Conventions

The style conventions that are used in documenting SAS syntax include uppercase
bold, uppercase, and italic:

UPPERCASE BOLD
identifies SAS keywords such as the names of functions or statements. In this
element, the keyword ERROR is written in uppercase bold:

    ERROR <message>;

UPPERCASE
identifies arguments that are literals.

In this example of the CMPMODEL= system option, the literals include BOTH,
CATALOG, and XML:
**CMPMODEL=** BOTH | CATALOG | XML |

*italic*
identifies arguments or values that you supply. Items in italic represent user-supplied values that are either one of the following:

- nonliteral arguments. In this example of the LINK statement, the argument *label* is a user-supplied value and therefore appears in italic:
  ```
  LINK *label*;
  ```
- nonliteral values that are assigned to an argument.
  In this example of the FORMAT statement, the argument DEFAULT is assigned the variable *default-format*:
  ```
  FORMAT variable(s) <format > <DEFAULT = default-format> ;
  ```

---

**Special Characters**

The syntax of SAS language elements can contain the following special characters:

- an equal sign identifies a value for a literal in some language elements such as system options.
  In this example of the MAPS system option, the equal sign sets the value of MAPS:
  ```
  MAPS=location-of-maps
  ```
- angle brackets identify optional arguments. A required argument is not enclosed in angle brackets.
  In this example of the CAT function, at least one item is required:
  ```
  CAT (item-1 <, item-2, …>)
  ```
- a vertical bar indicates that you can choose one value from a group of values. Values that are separated by the vertical bar are mutually exclusive.
  In this example of the CMPMODEL= system option, you can choose only one of the arguments:
  ```
  CMPMODEL= BOTH | CATALOG | XML
  ```
- an ellipsis indicates that the argument can be repeated. If an argument and the ellipsis are enclosed in angle brackets, then the argument is optional. The repeated argument must contain punctuation if it appears before or after the argument.
  In this example of the CAT function, multiple *item* arguments are allowed, and they must be separated by a comma:
  ```
  CAT (item-1 <, item-2, …>)
'value' or "value"
indicates that an argument that is enclosed in single or double quotation marks must have a value that is also enclosed in single or double quotation marks.

In this example of the FOOTNOTE statement, the argument text is enclosed in quotation marks:

```sas
FOOTNOTE <n> <ods-format-options 'text' | "text">;
```

; a semicolon indicates the end of a statement or CALL routine.

In this example, each statement ends with a semicolon:

```sas
data namegame;
  length color name $8;
  color = 'black';
  name = 'jack';
  game = trim(color) || name;
run;
```

References to SAS Libraries and External Files

Many SAS statements and other language elements refer to SAS libraries and external files. You can choose whether to make the reference through a logical name (a libref or fileref) or use the physical filename enclosed in quotation marks.

If you use a logical name, you typically have a choice of using a SAS statement (LIBNAME or FILENAME) or the operating environment's control language to make the reference. Several methods of referring to SAS libraries and external files are available, and some of these methods depend on your operating environment.

In the examples that use external files, SAS documentation uses the italicized phrase file-specification. In the examples that use SAS libraries, SAS documentation uses the italicized phrase SAS-library enclosed in quotation marks:

```sas
infile file-specification obs = 100;
libname libref 'SAS-library';
```
About This Book
What's New in the SAS 9.4 Companion for UNIX Environments

Overview

The following categories list the areas of change for SAS in UNIX environments:

- “Accessing SAS Viya” on page xv
- “Default Updates” on page xvi
- “SAS Command” on page xvi
- “SAS Procedures” on page xvii
- “SAS Statements” on page xvii
- “SAS System Options” on page xviii
- “System Performance and Maintenance” on page xx
- “Documentation Enhancements” on page xx

Accessing SAS Viya

Beginning in SAS 9.4M5, if you have SAS Viya on your system, you can begin a CAS session from your SAS 9.4 interface. For more information, see Chapter 2, “Connecting to the CAS Server,” on page 37.

Information about whether features are included in SAS Viya has been added throughout the book.
Default Updates

Default for LRECL= Option Is Now 32,767

The default value for LRECL= has changed from 256 to 32,767. If you are using fixed length records (RECFM=F), the default value for LRECL= is 256.

Default for MEMSIZE System Option Is Now 2G

In SAS 9.4, the default value for the MEMSIZE system option has changed from 512M to 2G. In addition, when you specify -MEMSIZE MAX during invocation, the value of MEMSIZE is adjusted accordingly based on both page size and virtual memory limit that is available for processes.

Default for SORTSIZE System Option Is Now 1G

The default value for the SORTSIZE= system option has changed from 256M to 1G. The default value for the SORTSIZE= option for the SORT procedure is based on the value of the SORTSIZE= system option.

SAS Command

SETENV | UNSETENV

The SETENV | UNSETENV command is new. You can use the SETENV command to define an environment variable by providing a variable name, a variable value, or both. You can use the UNSETENV command to delete an environment variable by specifying a variable name.

Run Lua Files from the SAS Command Line

You can run an external Lua script (*.lua or *.luc file) from the SAS command line using the -SYSIN option. You can also run an external Lua script in a SAS session.
using an %INCLUDE statement. Support for running external Lua files was added in SAS 9.4M3.

SAS Procedures

BMDP Procedure

In SAS 9.4M2, the BMDP procedure has been deprecated. If you call the BMDP procedure, SAS does not attempt to run BMDP software. However, the BMDP engine, which enables SAS to convert to and from BMDP files, is still available.

CONTENTS Procedure

In SAS 9.4M3, the CONTENTS procedure for UNIX displays the size of a file in KB, MB, or GB, as appropriate, labeled as File Size. This value is an approximation. If you need to know the exact size of a file, the value File Size (bytes) is still provided in the output for the CONTENTS procedure as well.

SAS Statements

FILE and FILENAME Statements: PERMISSION= Option

In SAS 9.4M2, a new option is available for the FILE and FILENAME statements. The PERMISSION= option enables you to specify Read, Write, and Execute permissions for the specified fileref. You also specify whether the permissions that you set apply to you, to the group owner of the file, and to other users.

FILENAME Statement: Access Methods

The FILENAME statement has the following new access methods:

DATAURL
- enables you to read data from user-specified text.

HADOOP
- enables you to access files on a Hadoop Distributed File System (HDFS) whose location is specified in a configuration file.
ZIP
  enables you to access ZIP files.

In SAS 9.4M1, the following access methods are new:

ACTIVEMQ
  enables SAS programs to send messages to and receive messages from an ActiveMQ message broker through the HTTP protocol.

JMS
  enables SAS programs to send messages to and receive messages from any JMS API-compliant message service.

In SAS 9.4M1, a processing restriction for a SAS server in a locked-down state was implemented. In SAS 9.4M2, the following FILENAME statement access methods are not accessible (enabled) when SAS is in a locked-down state: EMAIL, FTP, HADOOP, SOCKET, and URL. However, your SAS server administrator can re-enable one or more of these access methods so that they are accessible when SAS is in the locked-down state.

---

SAS System Options

System Option Enhancement

In SAS 9.4M5, you can specify the following system options using KB, MB, or GB syntax notation:

- **BUFNO**
- **BUFSIZE**
- **CATCACHE**
- **MAXMEMQUERY**
- **MEMSIZE**
- **MSYMTABMAX**
- **MVARSIZE**
- **OBS**
- **REALMEMSIZE**
- **SORTCUT**
- **SORTCUTP**
- **SORTSIZE**

For example, you can specify the value of BUFSIZE as 2MB in either of the following ways:

- `-bufsize=2M`
- `-bufsize=2MB`

---

ALIGNSASIOFILES System Option

The new ALIGNSASIOFILES system option aligns the pages of data in a SAS data set to improve performance.
FILELOCKWAIT= System Option
The new FILELOCKWAIT system option sets the number of seconds that SAS waits for a locked file to become available.

HOSTINFOLOG System Option
The new HOSTINFOLOG system option specifies to write additional operating environment information in the SAS log when SAS starts.

MVARSIZE System Option
In SAS 9.4M3, the default for the MVARSIZE system option changed from 32K to 65534.

OPLIST System Option Enhancement
In SAS 9.4M2, the OPLIST system option automatically masks any password values that are specified when invoking SAS. Only the masked values appear in the SAS log.

RTRACE System Option Argument
The RTRACE system option, which produces a list of resources that are read or loaded during a SAS session, has a new argument called VER. This argument writes the version number and other trace information for each module that SAS reads or loads.

RTRACELOC System Option Enhancement
In SAS 9.4M2, you can expand the filename that is generated by the RTRACELOC system option to include the process ID, date, and system time. Include %p, %d, or %t, respectively, to include these values in the filename (for example, mytrace.%d.%t.%p).
SAS Environment Variable: AUTHINFO

In SAS 9.4M5, support for a new environment variable, AUTHINFO, was added. Use this environment variable to specify the location of the authinfo file that you use to authenticate to a CAS server.

System Performance and Maintenance

Measuring System Performance

In SAS 9.4M1, documentation of the iotest.sh tool for measuring system performance was added. A new chapter, “Performance Considerations under UNIX,” explains the use of this tool.

Cleanwork Utility

In SAS 9.4M4, two new options were added to the cleanwork utility. These options are -V to produce verbose output and -LOG logfile to save the output of the cleanwork command to a log file.

Documentation Enhancements

How File Extension Delimiters Are Handled

A section about how file extension delimiters are handled was added. This section explains the use of periods as delimiters.

Supported File Extensions

In SAS 9.4M4, the table that lists file extensions for SAS file types has been updated to include SAS Scalable Performance Data Engine component files and
SAS Scalable Performance Data Server files. These files end with the file extension .spds9. For more information, see Table 3.1 on page 46.

End-of-Line Delimiters

In SAS 9.4M3, either a line feed alone or a carriage return and a line feed are recognized as an end-of-line delimiter. If you need to explicitly define the end-of-line delimiter, use the TERMSTR= host option for FILE, FILENAME, and INFILE statements.

Spaces within a System Option

If the value of a system option includes a space, you must enclose the value in quotation marks. For example, here is how you would specify a value for BUFSIZE that includes a space:

```bash
-bufsize='3 k';
```

Spaces within the SYSPARM= Macro Variable Value

When you invoke the SYSPARM= macro variable on the SAS command line for a value that includes a space, you must invoke it as follows:

```bash
sas --sysparm "my value"
```

Distributing Multiple Utility Files to Different Destinations

In the SORT procedure, you can distribute multiple utility files that are written by one threaded procedure to different locations. Each location that is specified for the UTILLOC option identifies a single location at which utility files can be distributed. If multiple locations are specified, then the locations are used on a rotating basis by SAS applications as utility files are required.

Environment Variables under UNIX

In SAS 9.4M2, a new chapter was added to explain environment variables that are used under UNIX environments. This chapter includes the SASV9_CONFIG, SASV9_OPTIONS, and the PATHENCODING environment variables.

In SAS 9.4M2, any path that you provide in a SAS program must include characters that are recognized by both the PATHENCODING environment variable and by the SAS session encoding. Specifically, to specify a PATHENCODING value of UTF-8 in a SAS session that uses English (LANG=EN), you must specify a SAS session encoding of UTF-8 or SAS_U8.
Processing Restriction for Server in a Locked-Down State

In SAS 9.4M1, a processing restriction for a SAS server in a locked-down state is new. If you are running in a client/server environment (for example, if you are running SAS Enterprise Guide), the SAS server administrator can create an environment where your SAS client has access to a set of directories and files. All other directories and files are inaccessible or locked down. When a SAS server is in a locked-down state, these SAS functions and CALL routines are not available:

- ADDR
- ADDRLONG
- CALL MODULE
- CALL POKE
- CALL POKE LONG
- PEEK
- PEEKC
- PEEKCLONG
- PEEKLONG

**Note:** Only the CALL MODULE routine and PEEKLONG function are listed in this document. The CALL MODULE routine and PEEKLONG function have properties that are specific to UNIX.

Function Key Definitions

In SAS 9.4M5, a table that lists the default key definitions has been added to the information about displaying function key definitions.

Administration Utilities That Are Available under UNIX

In SAS 9.4M3, a new chapter was added that described useful administration utilities that are available. These utilities assist in verifying user authentication and identifying key descriptive information about SAS images.

In SAS 9.4M5, these authentication and image description utilities were moved into Appendix 2, “Tools for the System Administrator,” on page 527 so that all system administrator utilities can be found in the same place.

Results of the SASUMGMT Utility

For SAS 9.4M5, a list of return codes and their meanings was added to the documentation for the SASUMGMT utility.
Accessing EBCDIC Data

In SAS 9.4M2, a new appendix, Appendix 4, “Using EBCDIC Data on ASCII Systems,” on page 587 was added. This appendix provides background about EBCDIC and ASCII data representation. This appendix includes examples of different methods of using EBCDIC data on an ASCII machine.

Starting SAS Sessions in UNIX Environments

Invoking SAS

A SAS session is invoked using a link within the $\texttt{SASROOT}$ directory. (The $\texttt{SASROOT}$ directory is a term that represents the name of the directory or folder in which SAS is installed at your site or on your computer.) Your UNIX administrator typically adds this link to the list of commands for your operating environment. For more information about the $\texttt{SASROOT}$ directory, see “Introduction to the $\texttt{SASROOT}$ Directory” on page 521.

Ask your system administrator for the command that invokes SAS at your site. At many sites, the command to invoke SAS is $\texttt{sas}$, but a different command might have been defined during the SAS installation process at your site. This documentation assumes that SAS is invoked by the $\texttt{sas}$ command.

Note: Before you start your SAS session, review the different techniques for interrupting and terminating your SAS session. For more information, see “Exiting or Interrupting Your SAS Session in UNIX Environments” on page 30. Also, if you cannot stop your SAS session, contact your system administrator.
SAS Invocation Scripts

SAS is invoked by scripts that are located under the \$SASROOT directory. Your system administrator typically defines a link or alias that you can use to invoke SAS. You can use that link or alias without specifying the full path to the SAS executable.

For SAS 9, a SAS invocation script is created for each language that is installed. An invocation script is named using the language code of the installed language. For example, `sas_en` invokes the English version of SAS. All languages are installed in all locations. The typical path to the SAS invocation script is `/usr/local/sas`.

For SAS Viya, the SAS invocation script is typically located in `/opt/sas/spre/home/bin/sas`, and the executable is `sas_u8`.

For more information about setting up SAS, see the installation documentation for the UNIX environment.

SAS Configuration Files

SAS creates a separate configuration file for each language that is installed. The language-specific configuration files have the form `!SASROOT/nls/<language>/sasv9.cfg` for each language. An additional configuration file that is language independent is `!SASROOT/sasv9.cfg`. This master configuration file in `!SASROOT/nls/<language>/` is used by all languages in addition to the language-specific files in `!SASROOT/nls/<language>/`. You can modify these configuration files to meet your needs. For information about how to customize SAS configuration files, see "Customizing Your SAS Session By Using Configuration and Autoexec Files" on page 25.

Syntax of the SAS Command

The general form of the SAS command is as follows:

```
  sas <-option1...-option-n> <filename>
  sas --sysin filename
```

You can use these arguments with the SAS command:

- `option1 ... -option-n` specifies SAS system options to configure your session or X command line options. For more information, see "SAS System Options under UNIX" on page 376 and "X Command Line Options" on page 15. If you omit any options (either on the command line or in the configuration file), the SAS (or site-specific) default options are in effect.

- `filename` specifies the name of the file containing the SAS program to be executed. Specifying a filename on the SAS command invokes a batch SAS session. Omit the filename to begin an interactive session.
If the file is not in the current directory, specify its full pathname. A .sas extension is inferred if the full pathname is not given.

**Note:** This command can fail in cases where an option does not recognize `filename`. In this case, `-sysin filename` is required.

---

**Example: Invoke an Interactive SAS Session**

To invoke an interactive SAS session, without specifying any SAS system options, enter:

```
sas
```

The execution mode depends on your default settings. For more information, see “Selecting a Method of Running SAS in UNIX Environments” on page 7.

To specify the WORK and MEMSIZE system options when you invoke SAS, you might enter this command:

```
sas -work /saswork -memsize 4G
```

---

**What If SAS Does Not Start?**

There are several reasons why SAS might not start. Some common reasons are listed here:

- SAS does not start if you specify an autoexec file that does not exist. An error message appears in the SAS log stating that the physical file does not exist.
- SAS does not start if the configuration file cannot be found. This error normally indicates an installation problem.
- SAS does not start if the Work directory cannot be found. You can specify a Work directory using the WORK system option.
- SAS does not start if you specify invalid options, such as a misspelled option: `./sas -nodms -stimerr` (stimerr is misspelled).

If SAS does not start, the SAS log might contain error messages that explain the failure. However, error messages that SAS issues before the SAS log is initialized are written to the console log. With the addition of better error handling, a failure could cause information to be written to standard output as well.

If the system is not patched correctly, SAS can generate an error such as NLS Extension Failure. This and other types of error messages indicate that the installation did not set up the search rules correctly.

Under UNIX, the STDOUT fileref specifies the location of the console log.
Running SAS in a Foreground or Background Process

UNIX is a multiprocessing operating system, so you can run multiple processes at the same time. For example, you can have one process running in the foreground and three in the background.

A foreground process executes while you wait for the prompt. That is, you cannot execute additional commands while the current command is being executed. After you enter a command, the shell starts a process to execute the command. After the system executes the command, the shell displays the prompt and you can enter additional commands. Here is an example of SAS executing as a foreground process:

```
sas
```

Running in the foreground enables you to access standard input and output.

A background process executes independently of the shell. After you enter a command, the shell starts a process to execute the command, and then issues the system prompt. You can enter other commands or start other background processes without waiting for your initial command to execute. Here is an example of the command that is used to execute a background process:

```
sas&
```

Note: Both the C shell and the Korn shell include commands that enable you to move jobs among three possible states: running in the foreground, running in the background, and suspended. If you run SAS in –nodms mode, the process stops waiting for input. In dms mode, control of standard output and input is retained by the shell.

Selecting a Method of Running SAS in UNIX Environments

You can run SAS in the SAS windowing environment mode, SAS Studio, interactive line mode, and batch mode:

- “Invoking SAS in the Windowing Environment” on page 9
- “Interactive Line Mode in UNIX Environments” on page 10
- “Batch Mode in UNIX Environments” on page 11
Ask your UNIX system administrator which interface or mode of operation is the default at your site.

---

**SAS Windowing Environment in UNIX Environments**

**Introduction to the SAS Windowing Environment**

**SAS Windows**

You interact with SAS through windows using the keyboard, mouse, menus, and icons. The windowing environment includes, but is not limited to, the Explorer, Program Editor, Output, Log, and Results windows. The following display shows the Explorer, Output, Log, and Program Editor windows. The ToolBox window is also displayed.

*Figure 1.1  Windows in the SAS Windowing Environment*

Your SAS session might default to the windowing environment interface. (You can change the default by using the config files.) If you want to use the windowing environment, you can start your SAS session as a foreground process, or as a background process by adding an ampersand (&) to your SAS command line. See “Running SAS in a Foreground or Background Process” on page 7 for an example of these SAS commands.

For more information about using the windowing environment, see "Definition of the SAS Windowing Environment" on page 158.
**What Is the Explorer Window?**

Explorer is a windowing environment for managing basic SAS software tasks such as viewing and managing data sets, libraries, members, applications, and output. The SAS Explorer is a central access point from which you can do the following:

- manipulate SAS data through a graphical interface
- access the Program Editor, Output, and Log windows (as well as other windows)
- view the results of SAS procedure output in the Results window
- import files into SAS

**What Are the Program Editor, Output, and Log Windows?**

The Program Editor, Output, and Log windows enable you to edit and execute SAS programs and display output. For more information about these windows, see the online SAS Help and Documentation.

---

**Invoking SAS in the Windowing Environment**

You can use the following commands to specify which windows open when a SAS session starts.

- You can open the Program Editor, Output, and Log windows by specifying the DMS system option:
  ```
  sas -dms
  ```

- You can open the Program Editor, Output, Log, and Results windows, as well as the Explorer window, by specifying the DMSEXP system option:
  ```
  sas -dmsexp
  ```

- You can open only the Explorer window by specifying the EXPLORER system option:
  ```
  sas -explorer
  ```
The default specification for invoking SAS is `sas -dmsexp`. This command displays the Program Editor, Output, Log, and Results windows as well as the Explorer window. If you invoke SAS without the `-dmsexp` option, the Explorer window is not displayed.

SAS also opens a toolbox from which you can open additional SAS windows. For more information about the toolbox, see Chapter 9, “Working in the SAS Windowing Environment,” on page 157.

### Exiting SAS in the Windowing Environment

To end your SAS session, enter the BYE or ENDSAS command in the command window, or select **File ➤ Exit** from the menu of the SAS session that you want to end.

### Interactive Line Mode in UNIX Environments

#### Introduction to Interactive Line Mode

If you are not using an X display, you can invoke SAS in interactive line mode by using the NODMS system option.

You enter SAS statements line by line in response to prompts issued by SAS. SAS reads the source statements from the terminal as you enter them. DATA and PROC steps execute when one of the following occurs:

- a RUN, QUIT, or DATALINES statement is entered
- another DATA or PROC statement is entered
- the ENDSAS statement is entered

To use interactive line mode, you must run SAS in the foreground.
Invoking SAS in Interactive Line Mode

To start an interactive line mode session, invoke SAS with the NODMS or NODMSEXP system option:

```
sas -nodms
sas -nodmsexp
```

By default, SAS log and procedure output (if any) appear on your display as each step executes.

You can also invoke SAS in interactive line mode and pass parameters to it:

```
sas -sysparm 'A B C'
```

The value \(A\ B\ C\) is assigned to the SYSPARM macro variable. You can include a program name, such as `progparm.sas` in the Program Editor or from the SAS command prompt, if you invoked SAS in line mode by using the –nodms option.

---

**Note:** NODMS is the default system option value.

---

After you invoke SAS, the `1?` prompt appears, and you can begin entering SAS statements. After you enter each statement, a line number prompt appears.

---

Exiting SAS in Interactive Line Mode

You can end the session by pressing the EOF key, usually Ctrl-D (see “Using Control Keys” on page 32) or by issuing the ENDSAS statement:

```
endsas;
```

The session ends after all SAS statements have executed.

---

Batch Mode in UNIX Environments

Introduction to Running SAS in Batch Mode

To run SAS in batch mode, you specify your SAS program name in the SAS invocation command. You can run batch mode in the foreground, in the background by specifying an ampersand at the end of the SAS command, or submit your application to the batch queue by using the `batch`, `at`, `nohup`, or `cron` UNIX commands. (For more information, see the UNIX man pages for the `batch`, `at`, `nohup`, or `cron` commands.) If you start your application with one of these UNIX commands and you log off from your system, then your application completes execution. If your application contains statements that start an interactive procedure
such as FSEDIT, then you need to run your batch application in the foreground or you need to specify the –noterminal option.

Invoking SAS in Batch Mode

To invoke SAS in batch mode, you must specify a filename in the SAS command. For example, if weekly.sas is the file that contains the SAS statements to be executed, and you want to specify the NODATE and LINESIZE system options, you would enter the following command:

```
sas weekly.sas -nodate -linesize 90
```

The command would run the program in the foreground. If you want to run the program in the background, add the ampersand to the end of the command:

```
sas weekly.sas -nodate -linesize 90 &
```

SAS creates a .log file and a .lst file in the current directory that contains the log and procedure output.

Submitting a Program to the Batch Queue

To submit your program to the batch queue, you can use the batch, at, nohup, or cron commands. For example, you could submit weekly.sas from your shell prompt as follows:

```
$ at 2am
sas weekly.sas
<control-D>
```

```
warning: commands will be executed using /usr/bin/sh
job 8400.a at Wed Mar 16 02:00:00 2011
$
```

If you create a file that contains the SAS command (for example, cmdfile.sh) that is necessary to run your program, then you can enter the following command at your shell prompt:

```
at 2am < cmdfile.sh
```

SAS sends the output to a file that has the same name as the program. The output file has an extension of .lst. The log file writes to a file with an extension of .log. Both of these files are written to your current directory. See the UNIX man pages for these commands for more information about submitting jobs to the batch queue. For more information about routing output, see Chapter 5, “Printing and Routing Output,” on page 103.

If you submit a file in batch mode, then a line that is greater than 256 bytes is truncated. An explicit message about this truncation is written to the SAS log.

Note: If your program contains statements that start an interactive procedure, such as the FSEDIT procedure, CATALOG procedure, or the REPORT procedure, you need to run your program as a foreground process, or use the –noterminal option.
Writing Data from an External File Using UNIX Pipes

You can use a UNIX pipe to write data from an external file to a SAS program. For example, suppose that your data resides in the external file `mydata` and your SAS program `myprog.sas` includes this statement:

```sas
infile stdin;
```

Issue this command to run `myprog.sas`, which reads data from the external file `mydata`:

```bash
cat mydata | sas myprog.sas
```

For information about using external files, see Chapter 4, “Using External Files and Devices,” on page 79. For information about another way to have a SAS program read data from an external file, see “File Descriptors in the Bourne and Korn Shells” on page 91.

---

Running SAS on a Remote Host in UNIX Environments

Introduction to Running SAS on a Remote Host

When you invoke SAS in an interactive mode, you can run SAS on your local host. Alternatively, you can run SAS on a remote host and interact with the session through an X server that runs on your workstation. The server provides the display services that are needed for the X Window System.

Most of the time, the server name is derived from the computer’s name. For example, if your computer is named `green`, the name of the server is `green:0.0`. In most cases, the X server will already be running when you log on. If you need to start your server manually, consult the documentation that is provided with your X Window System software.

To run SAS on a remote host, you must tell SAS which display to use by either setting the DISPLAY environment variable or specifying the `-display x` command line option.

Steps for Running SAS on a Remote Host

To run SAS on a remote host, you must tell SAS which display to use by either setting the DISPLAY environment variable before invoking SAS or by specifying the `-display x` as a SAS command line option. Then follow these steps:

1. Make sure that the clients running on the remote host have permission to connect to your server. With most X servers, authorization is controlled by using
an .Xauthority file that is located in the user's home directory. In addition, the xhost command can be used to circumvent authority. To use the xhost client to permit all remote hosts to connect to your server, enter the following command at the system prompt on the system that is running your X server:

```
xhost +
```

If your system does not control access with the xhost client, consult your system documentation for information about allowing remote access.

For information about editing and displaying authorization information, see the UNIX man page for xauth.

2 Log on to the remote system, or use a remote shell.

3 Identify your server as the target display for X clients that are run on the remote host. You can identify your server in one of two ways:

   a Set the DISPLAY environment variable. In the Bourne and Korn shells, you can set the DISPLAY variable as follows:

```
DISPLAY=green:0.0
export DISPLAY
```

   In the Korn shell, you can combine these two commands:

```
export DISPLAY=green:0.0
```

   In the C shell, you must use the UNIX `setenv` command:

```
setenv DISPLAY green:0.0
```

   The DISPLAY variable is used by all X clients on the system.

   Note: To determine the shell for your current system, type `ps` at the UNIX command prompt or check the value of the SHELL environment variable.

   b Use the DISPLAY system option. For example:

```
sas -display green:0.0
```

   If you have trouble establishing a connection, you can try using an IP address instead of a display name, for example:

```
-display 10.22.1.1:0.0
```

   Note: This option is a command line option for the X Window System, not for SAS. Specifying this option in a SAS configuration file or in the SASV9_OPTIONS environment variable might cause problems when you are running other interfaces.

---

**Preventing SAS from Attempting to Connect to the X Server**

To prevent SAS from attempting to connect to the X server, unset the DISPLAY environment variable and use the `-noterminal` SAS option on the command line. The `-noterminal` option specifies that you do not want to display the SAS session. You must specify this option to generate a graph in batch mode. You must also
Troubleshooting Connection Problems

If SAS cannot establish a connection to your display, it prints a message that indicates the nature of the problem and then terminates. An example of a message that you might receive is the following:

```
ERROR: The connection to the X display server could not be made.
Verify that the X display name is correct, and that you have access authorization. See the online Help for more information about connecting to an X display server.
```

Make sure that you have brought up the SAS session correctly. You might need to use the `xhost` client (enter `xhost +`) or some other method to change display permissions. You can also specify the NODMS system option when you invoke SAS to bring your session up in line mode.

If you are unable to invoke SAS, try running another application such as `xclock`. If you cannot run the application, you should contact your UNIX system administrator for assistance.

X Command Line Options

How to Specify X Window System Options

When you invoke some X clients, such as SAS, you can use command line options that are passed to the X Window System. In general, you should specify X Window System options after SAS options on the command line.

Supported X Command Line Options

The following list describes the X command line options that are available when you invoke a SAS session from the command prompt.

- `display host:server.screen`
  specifies the name or IP address of the terminal on which you want to display the SAS session. For example, if your display node is `wizard` whose IP address is `10.22.1.1:0.0`, you might enter this code:

  - `display wizard:0.0`

  Or you might enter this code:

  - `display 10.22.1.1:0.0`
-name instance-name
reads the resources in your SAS resource file that begin with instance-name. For example, name MYSAS reads the resources that begin with MYSAS:

MYSAS.dmsfont: Cour14
MYSAS.defaultToolbox: True

title string
specifies a title for your SAS session window. Titles can contain up to 64 characters. Window titles are displayed in the case in which they are entered, which can be lowercase, mixed case, or uppercase. To use multiple words in the title, enclose the words in single or double quotation marks. For example, title MYSAS produces MYSAS:Explorer in the title bar of the Explorer window.

-xrm string
specifies a resource to override any defaults. For example, the following resource turns off the Confirm dialog box when you exit SAS:

-xrm 'SAS.confirmSASExit: False'

Unsupported X Command Line Options

SAS does not support the following X command line options because their functionality is not applicable to SAS or is provided by SAS resources. For more information about SAS resources, see "Overview of X Resources" on page 186.

-geometry
Window geometry is specified by the SAS.windowHeight, SAS.windowWidth, SAS.maxWindowHeight, and SAS.maxWindowWidth resources.

-background, -bg
These options are ignored.

-bordercolor, -bd
These options are ignored. For a description of specifying the color of window borders, see "Defining Colors and Attributes for Window Elements (CPARMS)" on page 225.

-borderwidth, -bw
These options are ignored. The width of window borders is set by SAS.

-foreground, -fg
These options are ignored.

-font, -fn
SAS fonts are specified by the SAS.DMSFont, SAS.DMSboldFont, and SAS.DMSfontPattern resources.

-iconic
This option is ignored.

-reverse, -rv, +rv
These options are ignored. For more information about a description for specifying reverse video, see "Defining Colors and Attributes for Window Elements (CPARMS)" on page 225.

-selectionTimeout
Time-out length is specified by the SAS.selectTimeout resource.
The XSYNC command toggles synchronous communication between SAS and the X server.

This option is ignored.

---

**Executing Operating System Commands from Your SAS Session**

### Deciding Whether to Run an Asynchronous or Synchronous Task

You can execute UNIX commands from your SAS session either asynchronously or synchronously. When you run a command as an asynchronous task, the command executes independently of all other tasks that are currently running. To run a command asynchronously, you must use the SYSTASK statement. See "SYSTASK Statement: UNIX" on page 367 for information about executing commands asynchronously.

When you execute one or more UNIX commands synchronously, you must wait for those commands to finish executing before you can continue working in your SAS session. You can use the CALL SYSTEM routine, %SYSEEXEC macro program statement, X statement, and X command to execute UNIX commands synchronously. The CALL SYSTEM routine can be executed with a DATA step. The %SYSEEXEC macro statement can be used inside macro definitions, and the X statement can be used outside of DATA steps and macro definitions. You can enter the X command on any SAS command line. For more information, see "CALL SYSTEM Routine: UNIX" on page 304 and "Macro Statements in UNIX Environments" on page 337.

---

**Executing a Single UNIX Command**

### Single Commands

To execute only one UNIX command, you can enter the X command, X statement, CALL SYSTEM routine, or %SYSEEXEC macro statement as follows:

- **X command**
- **X command;**
- **CALL SYSTEM ('command');**
- **%SYSEEXEC command;**
Note: When you use the %SYSEXEC macro statement, if the UNIX command that you specify includes a semicolon, you must enclose the UNIX command in a macro quoting function. For more information about quoting functions, see SAS Macro Language: Reference.

Example 1: Executing a UNIX Command By Using the X Statement

You can use the X statement to execute the ls UNIX command (in a child shell) as follows:

```
x ls -l;
```

Example 2: Executing a UNIX Command By Using the CALL SYSTEM Routine

Inside a DATA step, you can use the CALL SYSTEM routine to execute a cd command, which changes the current directory of your SAS session:

```
data _null_;
call system ('cd /users/smith/report');
run;
```

The search for any relative (partial) filenames during the SAS session now begins in the /users/smith/report directory. When you end the session, your current directory is the directory in which you started your SAS session.

For more information about the CALL SYSTEM routine, see “CALL SYSTEM Routine: UNIX” on page 304.

How SAS Processes a Single UNIX Command

When you specify only one command, SAS checks to see whether the command is cd, pwd, setenv, or umask and, if so, executes the SAS equivalent of these commands. The SAS cd and pwd commands are equivalent to their Bourne shell counterparts. The SAS setenv command is equivalent to its C shell namesake. The SAS umask command is equivalent to the numeric mode of the umask command supported by the Bourne, Korn, and C shells. These four commands are built into SAS because they affect the environment of the current SAS session. When executed by SAS software, they affect only the SAS environment and the environment of any shell programs started by the SAS session. They do not affect the environment of the shell program that began your SAS session.

If the command is not cd, pwd, or setenv, SAS starts a shell in which it executes the command that you specified. The shell that is used depends on the SHELL environment variable. If the command is umask, but you do not specify a mask, then SAS passes the command to the shell in which the current SAS session was started. For more information about the umask command, see “Changing the File Permissions for Your SAS Session” on page 19.
Executing Several UNIX Commands

Executing UNIX Commands

You can also use the X command, X statement, CALL SYSTEM routine, and
%SYSEXEC macro statement to execute several UNIX commands:

\[
\text{X } \text{'command-1';...;command-n'} \\
\text{X } \text{'command-1';...;command-n'}; \\
\text{CALL SYSTEM ('command-1';...;command-n');} \\
\text{%SYSEXEC quoting-function(command-1;...;command-n);} \\
\]

Separate each UNIX command with a semicolon (;).

**Note:** When you use the %SYSEXEC macro statement to execute several UNIX
commands, because the list of commands uses semicolons as separators, you must
enclose the string of UNIX commands in a macro quoting function. For more
information about quoting functions, see *SAS Macro Language: Reference*.

Example: Executing Several Commands Using the
%SYSEXEC Macro

The following code defines and executes a macro called pwdls that executes the
pwd and ls -l UNIX commands:

```sas
%macro pwdls;
   %sysexec %str(pwd;ls -l);
%mend pwdls;
```

This example uses %str as the macro quoting function.

How SAS Processes Several UNIX Commands

When you specify more than one UNIX command (as a list of commands separated
by semicolons), SAS passes the entire list to the shell. SAS does not check for the
cd, pwd, setenv, or umask commands as it does when a command is specified by
itself (and not in a list separated by semicolons).

For more information about how SAS processes the cd, pwd, setenv, or umask
commands, see “How SAS Processes a Single UNIX Command” on page 18.

Changing the File Permissions for Your SAS Session

At invocation, a SAS session inherits the file permissions from the parent shell. Any
file that you create inherits these permissions. If you want to change or remove file
permissions from within SAS, issue the following command in the X statement:

\[
\text{umask} \\
\]

The umask command applies a new "mask" to a file, that is, it sets new file
permissions for any new file that you create. In this way, the `umask` command can provide file security by restricting access to new files and directories for the current process.

The default value for `umask` varies. Some systems, like Secure Linux, use mandatory access control, and the `umask` default is the same with or without Secure Linux enabled. Other systems use 022 as the default. System administrators can set their own default value, and you can check your default and change it in your own `.kshrc`, `.cshrc`, or `.profile` files. These values affect all child processes that are executed in the shell. Any subsequent file that you create during the current SAS session inherits the permissions that you specified. The permissions of a file created under a given mask are calculated in octal representation.

**Note:** The value of a mask can be either numeric or symbolic. For more information about this command, see the UNIX man page for `umask`.

In addition, you can use the `PERMISSION=` option in the `FILE` or `FILENAME` statement to control the permissions for individual output files. For more information, see “FILE Statement: UNIX” on page 343 or “FILENAME Statement: UNIX” on page 346.

---

**Executing X Statements in Batch Mode**

If you run your SAS program in batch mode and if your operating system supports job control, the program is suspended when an X statement within the program needs input from the terminal.

If you run your SAS program from the batch queue by submitting it with the `at` or `batch` commands, SAS processes any X statements as follows:

- If the X statement does not specify a command, SAS ignores the statement.
- If any UNIX command in the X statement attempts to get input, it receives an end-of-file (standard input is set to `/dev/null`).
- If any UNIX command in the X statement writes to standard output or standard error, the output is mailed to you unless it was previously redirected.

---

**Customizing Your SAS Registry Files**

SAS registry files store information about the SAS session. The SAS registry is the central storage area for configuration data for SAS. The following list identifies some of the data that is stored in the registry:

- the libraries and file shortcuts that SAS assigns at start–up. These shortcuts could include secure information, such as your password.
- the printers that are defined for use and their print setup.
- configuration data for various SAS products.
Customizing Your SAS Session By Using System Options

Ways to Customize Your SAS Session

You can customize your SAS environment in several ways. One way is through the use of SAS system options. For information about other ways to customize a SAS session, see “Overview of Customizing SAS in X Environment” on page 186.

Ways to Specify a SAS System Option

SAS options can be specified in one or more ways:

- in a configuration file
- in the SASV9_OPTIONS environment variable
- in the SAS command
- in an OPTIONS statement (either in a SAS program or an autoexec file) (An autoexec file contains SAS statements that are executed automatically when SAS is invoked. The autoexec file can be used to specify some SAS system options, as well as to assign librefs and filerefs to data sources that are used frequently.)
- in the System Options window

Any options that do not affect the initialization of SAS, such as CENTER and NOCENTER, can be specified and changed at any time.

Some options can be specified only in a configuration file, in the SASV9_OPTIONS variable, or in the SAS command. These options determine how SAS initializes its interfaces with the operating system and the hardware; they are often called configuration options. After you start a SAS session, these options cannot be changed. Usually, configuration files specify options that you would not change very
Often. In those cases when you need to change an option just for one job, specify the change in the SAS command.

Overriding the Default Value for a System Option

The default values for SAS system options will be appropriate for many of your SAS programs. However, you can override a default setting using one or more of the following methods:

configuration file
Modify your current configuration file (see “Order of Precedence for Processing SAS Configuration Files” on page 27) or create a new configuration file. Specify SAS system options in the file by preceding each with a hyphen. For ON or OFF options, just list the keyword corresponding to the appropriate setting. For options that accept values, list the keyword identifying the option followed by the option value. All SAS system options can appear in a configuration file.

For example, a configuration file might contain these option specifications:

- nocenter
- verbose
- linesize 64

SASV9_OPTIONS environment variable
Specify SAS system options in the SASV9_OPTIONS environment variable before you invoke SAS. See “Defining Environment Variables in UNIX Environments” on page 285.

Settings that you specify in the SASV9_OPTIONS environment variable affect SAS sessions that are started when the variable is defined.

For example, in the Korn shell, you would use the following code:

export SASV9_OPTIONS='-fullstimer -nodate'

SAS command
Specify SAS system options in the SAS command. Precede each option with a hyphen:

sas -option1 -option2...

For ON or OFF options, list the keyword corresponding to the appropriate setting. For options that accept values, list the keyword that identifies the option, followed by the option value. Here is an example:

sas -nodate -work mywork

In general, settings that you specify in the SAS command last for the duration of the SAS session. For options that can be changed within the session, command-line settings last until you change them. All options can be specified in the SAS command.

OPTIONS statement within a SAS session
Specify SAS system options in an OPTIONS statement at any point within a SAS session. The options are set for the duration of the SAS session or until you change them. When you specify an option in the OPTIONS statement, do not precede its name with a hyphen (-). If the option has an argument, use = after the option name. Here is an example:

options nodate linesize=72;
OPTIONS statement in an autoexec file

Specify SAS system options in an OPTIONS statement in an autoexec file. An autoexec file contains SAS statements that are executed automatically when SAS is invoked. The autoexec file can be used to specify some SAS system options, as well as to assign librefs and filerefs to data sources that are used frequently. For example, your autoexec file could contain the following statements:

```sas
options nodate pagesize=80;
filename rpt '/users/myid/data/report';
```

System Options window

Change the SAS system options from within the System Options window.

In general, use quotation marks to enclose filenames and pathnames specified in the OPTIONS statement or the System Options window. Do not use quotation marks otherwise. Any exceptions are discussed under the individual option. To shorten filenames and pathnames that you specify, you can use the abbreviations listed in Table 3.3 on page 62.

---

When the Value of a System Option Includes a Space

If the value of a system option includes a space, you must enclose the value in quotation marks on the command line or in a config file. The following examples show the correct syntax:

- `bufsize '3 k';`
- `bottommargin '2 in';`

If the value of a system option does not include a space, you do not need to enclose the value in quotation marks:

- `bufsize 3k;`
- `bottommargin 2in;`

---

How SAS Processes System Options That Are Set More Than Once

If the same system option is set more than once in the SAS command, in a configuration file, or in the SASV9_OPTIONS environment variable, only the most recent specification is used. The other specifications are ignored. For example, the DMS option is ignored in the following SAS command:

```
sas -dms -nodms
```

The DMS option is ignored in the following configuration file:

```
-dms
-linewidth 80
-nodms
```
By default, if you specify the HELPLOC, MAPS, MSG, SAMPLC, SASAUTOS, or SASHELP system option more than once, the most recent specification is the value that SAS uses. If you want to add additional pathnames to the pathnames already specified by one of these options, you must use the APPEND or INSERT system option. For more information, see the "APPEND System Option: UNIX" on page 382 and "INSERT System Option: UNIX" on page 412.

---

**How SAS Processes System Options That Are Set in Multiple Places**

**System Options Set in Multiple Places**

If the same system option is set in more than one place, only the most recent specification is the value that SAS uses. The following places are listed in order of precedence. For example, a setting made in the System Options window or in the OPTIONS statement overrides any other setting. However, if you set a system option using the SASV9_OPTIONS environment variable, this setting overrides only the setting for the same system option in your configuration file.

**Order of Precedence When System Options Are Processed**

The order of precedence when system options are processed is as follows:

1. System Options window or OPTIONS statement (from a SAS session or job).
2. An autoexec file that contains an OPTIONS statement (after SAS initializes). (An autoexec file contains SAS statements that are executed automatically when SAS is invoked. The autoexec file can be used to specify some SAS system options, as well as to assign librefs and filerefs to data sources that are used frequently.)
3. SAS command.
4. SASV9_OPTIONS environment variable.
5. Configuration files (before SAS initializes). For more information, see “Order of Precedence for Processing SAS Configuration Files” on page 27.

---

**Note:** If you create a configuration file in your home directory and the NOUSERCONFIG system option is set, the configuration file in your home directory is skipped.

---

For example, if a configuration file specifies NOSTIMER, you can override the setting in the SAS command by specifying –FULLSTIMER.

By default, if you specify the HELPLOC, MAPS, MSG, SAMPLC, SASAUTOS, or SASHELP system option more than one time, the most recent value that is specified is the value that SAS uses. If you want to add pathnames to those that are already specified by one of these options, use the APPEND or INSERT system options to add the new pathnames. For more information, see the "APPEND System Option: UNIX" on page 382 and "INSERT System Option: UNIX" on page 412.
Customizing Your SAS Session By Using Configuration and Autoexec Files

Customizing Your SAS Session

You can customize your SAS environment in several ways. To customize your SAS environment at the point of invocation, you can use configuration and autoexec files. For information about how to customize a SAS session using the windowing environment, see “Overview of Customizing SAS in X Environment” on page 186.

Introduction to Configuration and Autoexec Files

Defining Configuration and Autoexec Files

You can customize your SAS session by defining configuration and autoexec files. You can use these files to specify system options and to execute SAS statements automatically whenever you start a SAS session. SAS system options control many aspects of your SAS session, including output destinations, the efficiency of program execution, and the attributes of SAS files and libraries. For a complete description of SAS system options, see SAS System Options: Reference.

For SAS 9.4, the configuration file is typically named sasv9.cfg, and the autoexec file is named autoexec.sas. These files typically reside in the directory where SAS was installed. By default, this directory is the !SASROOT directory.

Note: You generally store configuration files on multiple SAS servers. The options that are specified pertain to the specific SAS server on which a configuration file is stored. For example, if the WORK option is defined in a configuration file on the workspace server, then the assigned Work directory must be valid on that workspace server.

You can have customized configuration and autoexec files in your user home directory. If you do, then SAS uses the customizations specified in these files when you start a SAS session. For more information about the order of precedence SAS uses when processing configuration files, see “Order of Precedence for Processing SAS Configuration Files” on page 27.

SAS system options can be restricted by a UNIX system administrator, so that once they are set by the administrator, they cannot be changed by a user. A system option can be restricted globally, by group, and by user. For more information, see the configuration guide for the UNIX environment on the SAS Support site, and see “Restricted Options” in SAS System Options: Reference.
Using the AUTOEXEC System Option

The AUTOEXEC system option specifies the autoexec file. The autoexec file contains SAS statements that are executed automatically when you invoke SAS, or when you start another SAS process. The autoexec file can contain any SAS statements. For example, your autoexec file can contain LIBNAME statements for SAS libraries that you access routinely in SAS sessions.

SAS looks for the AUTOEXEC system option in the following places. It uses the first AUTOEXEC system option that it finds.

- in the command line
- in the SASV9_OPTIONS environment variable
- in the configuration file

If neither the AUTOEXEC nor NOAUTOEXEC system option is found, SAS looks for the autoexec file in three directories in the following order:

1. your current directory
2. your home directory
3. the `!SASROOT` directory (for more information, see Appendix 1, “The !SASROOT Directory,” on page 521)

SAS uses the first autoexec file that it finds to initialize the SAS session. If you want to see the contents of the autoexec file for your session, use the ECHOAUTO system option when you invoke SAS.

Inserting and Appending Autoexec Files

You can concatenate files in your autoexec file by using the following system options with the AUTOEXEC system option: “INSERT System Option: UNIX” on page 412 and “APPEND System Option: UNIX” on page 382. The autoexec file is always a text file. If your filename contains embedded blanks or special characters, you must enclose the filename in quotation marks. Otherwise, quotation marks are optional when one or more filenames are specified.

You can use the following syntax to concatenate autoexec files:

```
-autoexec "(/path1/autoexec.sas /path2/autoexec.sas /path3/autoexec.sas)"
```

You can use the following syntax with the INSERT system option:

```
-insert autoexec "a.sas" -insert autoexec "b.sas"
```

You can use the following syntax with the APPEND system option:

```
-append autoexec "a.sas" -append autoexec "b.sas"
```

If any file in a concatenated autoexec list does not exist or cannot be opened (for example, if you are not authorized for Read access), SAS issues error messages to the log. SAS terminates without executing any of the files in the list. The final SAS exit code is 103, which indicates system start-up failure.

Differences between Configuration and Autoexec Files

The differences between configuration files and autoexec files are as follows:
Configuration files can contain only SAS system option settings. Autoexec files can contain any valid SAS statement. For example, you might want to create an autoexec file that includes an OPTIONS statement to change the default values of various system options. The autoexec file can also contain LIBNAME and FILENAME statements for the SAS libraries and external files that you use most often.

Configuration files are processed before SAS initializes while autoexec files are processed immediately after SAS initializes but before it processes any source statements. An OPTIONS statement in an autoexec file is equivalent to submitting an OPTIONS statement as the first statement of your SAS session.

Creating a Configuration File

To create a configuration file, follow these steps:

1. Use a text editor to write the SAS system options into a UNIX file. Save the file as either sasv9.cfg or .sasv9.cfg. (For more information, see “Order of Precedence for Processing SAS Configuration Files” on page 27.)

2. Specify one or more system options on each line. Use the same syntax that you would use for specifying system options with the SAS command, but do not include the SAS command itself. For example, a configuration file might contain the following lines:
   - nocenter
   - verbose
   - linesize 64
   - work /users/myid/tmp

3. Save and close the configuration file.

Order of Precedence for Processing SAS Configuration Files

SAS is shipped with a default configuration file in the !SASROOT directory. Your onsite SAS personnel can edit this configuration file so that it contains whichever options are appropriate to your site.

You can also create one or more of your own configuration files. SAS reads option settings from each of these files in the order listed below.

Note: If you create a configuration file in your home directory and the NOUSERCONFIG system option is set, the configuration file in your home directory is skipped.

1. sasv9.cfg in the !SASROOT directory. (See “Contents of the !SASROOT Directory” on page 521.)

2. sasv9_local.cfg in the !SASROOT directory. (See “Contents of the !SASROOT Directory” on page 521.)
3 .sasv9.cfg in your home directory. (Notice the leading period.)
4 sasv9.cfg in your home directory.
5 sasv9.cfg in your current directory.
6 any restricted configuration files. Restricted configuration files contain system options that are set by the site administrator and cannot be changed by the user. Options can be restricted globally, by group, or by user. For more information about restricted configuration files, see the configuration guide for the UNIX environment.

For future releases of SAS, the names of these files will change accordingly.

For each system option, SAS uses the last setting that it encounters. Any other settings are ignored. For example, if the WORKPERMS system option is specified in sasv9.cfg in the $SASROOT directory and in sasv9.cfg in your current directory, SAS uses the value specified in sasv9.cfg in your current directory.

Specifying a Configuration File for SAS to Use

When you specify a configuration file for SAS to use, you bypass the search of the configuration files listed in “Order of Precedence for Processing SAS Configuration Files” on page 27.

Note: SAS still processes any restricted configuration files that exist. The settings in these files take precedence over the settings in the configuration file that you specify.

If you set both SASV9_OPTIONS and SASV9_CONFIG, SAS always uses SASV9_OPTIONS. SASV9_CONFIG is used only if you do not use –config in the command line.

To specify a configuration file, complete one of the following steps:

- specify a configuration file with the CONFIG system option in the SAS command:
  ```bash
  sas -config filename
  ```

- specify a configuration file in the SASV9_OPTIONS environment variable. See “Defining Environment Variables in UNIX Environments” on page 285. For example, in the Korn shell, you would use the following:
  ```bash
  export SASV9_OPTIONS='-config filename'
  ```

- define the environment variable SASV9_CONFIG. See “Defining Environment Variables in UNIX Environments” on page 285. For example, in the Korn shell, you would use the following:
  ```bash
  export SASV9_CONFIG=filename
  ```

*filename* is the name of a file that contains SAS system options.

If you have specified a configuration file in the SASV9_OPTIONS or SASV9_CONFIG environment variables, you can prevent SAS from using that file by specifying NOCONFIG in the SAS command.

If SAS cannot find SASV9_OPTIONS, the following message is written to the SAS log:
Determining the Completion Status of a SAS Job in UNIX Environments

The exit status for the completion of a SAS job is returned in $STATUS for the C shell, and in $? for the Bourne and Korn shells. A value of 0 indicates normal termination. You can affect the exit status code by using the ABORT statement. The ABORT statement takes an optional integer argument, n, which can range from 0 to 255.

Note: Return codes of 0–6 and return codes greater than 977 are reserved for use by SAS.

The following table summarizes the values of the exit status code.

Table 1.1 Exit Status Code Values

<table>
<thead>
<tr>
<th>Condition</th>
<th>Exit Status Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>All steps terminated normally</td>
<td>0</td>
</tr>
<tr>
<td>SAS issued warnings</td>
<td>1</td>
</tr>
<tr>
<td>SAS issued errors</td>
<td>2</td>
</tr>
<tr>
<td>User issued ABORT statement</td>
<td>3</td>
</tr>
<tr>
<td>User issued ABORT RETURN statement</td>
<td>4</td>
</tr>
<tr>
<td>User issued ABORT ABEND statement</td>
<td>5</td>
</tr>
<tr>
<td>SAS could not initialize because of a severe error</td>
<td>6</td>
</tr>
<tr>
<td>User issued ABORT RETURN - n statement</td>
<td>n</td>
</tr>
<tr>
<td>User issued ABORT ABEND - n statement</td>
<td>n</td>
</tr>
</tbody>
</table>

If you specify the ERRORABEND SAS system option on the command line, and the job has errors, the exit status code is set to 5.

UNIX exit status codes are in the range 0-255. Numbers greater than 255 might not print what you expect because the code is interpreted as a signed byte.
Exiting or Interrupting Your SAS Session in UNIX Environments

Methods for Exiting SAS

Use one of the following methods to exit a SAS session:

- Select **File ➔ Exit** if you are using SAS in the windowing environment.
- Use `endsas;`.
- Enter **BYE** in the ToolBox if you are using SAS in the windowing environment.
- Use Ctrl+D if this control key sequence is your EOF command and if you are using SAS in interactive line mode.

Methods for Interrupting or Terminating SAS

Interrupting or Terminating SAS

In addition to the methods for exiting SAS, SAS provides methods for interrupting or terminating a SAS session. SAS does not recommend that you use these methods until you have tried to exit SAS by one of the methods listed in “Methods for Exiting SAS” on page 30.

You can interrupt or terminate SAS in the following ways:

- Press the interrupt or quit control key. Interrupt displays a dialog box while quit forces a shutdown. Using the quit control key is not recommended.
- Use the SAS: Session Management window.
- Enter the UNIX `kill` command. Use this command when all other methods of exiting SAS have failed. By default, the kill command is `kill -15` (SIGTERM).
  
  Using the UNIX `kill -9` command on a SAS process that is running might corrupt data sets that are open for Write or Update access.

Interrupting a SAS Process

The method that you use to interrupt a SAS process depends on how you invoke SAS.

- If you are running SAS in interactive line mode or in batch mode in the foreground, then you can use either of the following methods to interrupt SAS:
  
  - Press the control key sequence that is set to interrupt in the shell that invoked SAS. In most cases, this control key sequence is Ctrl+C. See the man page
for the `stty` command to determine the appropriate control key sequence for your environment.

- Use the `-SIGINT` option in the `kill` command. For more information, see “Using the UNIX kill Command” on page 34.

- If you are running the SAS windowing environment in the foreground, then click Interrupt in the SAS: Session Management window.

The interrupt signal sends a request to the supervisor to handle an interrupt. The interrupt signal is not handled until a safe point in the code is reached. A safe point is one that allows the interrupt handler to be run safely. The supervisor responds as soon as possible with a prompt or window that requests what type of interrupt action you want to take. During this time, normal processing of a DATA step or PROC step is suspended.

For example, when you interrupt a DATA step or PROC step, a Tasking Manager window, similar to the following, appears:

```
H64: Tasking Manager

Select:
1. Cancel Submitted Statements
2. Halt DATA step/PROC: DATASTEP
C. Cancel the dialog
T. Terminate the SAS System

1 2 C T
```

The following table explains each of the options in the window:
### Table 1.2 Options in the Tasking Manager Window

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>What This Option Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Cancel submitted statements</td>
<td>Selecting this option terminates the current DATA step or PROC step. Outstanding source code that is waiting to execute is flushed from the system. In interactive line mode, you return to the command prompt.</td>
</tr>
</tbody>
</table>
| 2      | Halt DATA step or PROC DATASTEP | Selecting this option sends an interrupt signal to the DATA step or PROC step. The default behavior is for the DATA step or PROC step to terminate, and to execute the next statement.  
A procedure might specify its own handler to process the interrupt. In this case, the procedure might request more input from you. For example, SAS webAF has a different interrupt menu than PROC SQL.  
Note: If you are using a relational database, the interrupt signal might be handled differently, depending on which relational database you are using. |
| C      | Cancel the dialog box | Selecting this option cancels the interrupt, and you return to normal processing. |
| T      | Terminate SAS | Selecting this option causes the DATA step or PROC step to be terminated. Outstanding source code that is waiting to execute is flushed from the system. SAS exits as cleanly as possible. |

### Terminating a SAS Process

If you are running the SAS windowing environment in the foreground, click **Terminate** in the SAS: Session Management window. If you are running a SAS process in interactive line mode in the background, use control keys to terminate the SAS process, or use the `kill` command.

If you click **Terminate** in the SAS: Session Management window, a dialog box appears, confirming that you want to end the session. If you click **OK**, then the SAS session and any queries that are currently running are terminated. If you click **Cancel**, you are returned to the SAS session.

### Using Control Keys

Control keys enable you to interrupt or terminate your session by pressing the interrupt or quit key sequence. However, control keys can be used only when your SAS program is running in interactive line mode or in batch mode in the foreground. You cannot use control keys to stop a background job.
Note: You cannot use control keys to stop a batch job that has been submitted with the batch, at, nohup, or cron command.

Because control keys vary from system to system, issue the UNIX `stty` command to determine which key sends which signal. The `stty` command varies considerably among UNIX operating environments, so check the UNIX man page for `stty` before using the command. Usually, one of these forms of the command prints all of the current terminal settings:

```plaintext
stty
stty -a
stty everything
```

The output should contain lines similar to these:

```
intr = ^C; quit = ^\; erase = ^H;
kill = ^U; eof = ^D; eol = ^@ 
```

The caret (^) represents the Ctrl key. In this example, Ctrl+C is the interrupt key and Ctrl+U is the quit key. Quit is a more forceful termination and might result in data corruption. If you use –SIGTERM, SAS attempts to shut down the system correctly.

Using the SAS Session Manager

If you invoke SAS in the windowing environment, you can use the SAS session manager to interrupt or terminate your SAS session. The SAS session manager is automatically minimized when you start SAS. To interrupt or terminate your SAS session, open the SAS: Session Management window and click **Interrupt** or **Terminate**:

![SAS: Session Management window](image)

If asynchronous SAS/CONNECT tasks are running when you terminate a SAS session, these tasks are terminated and no warning message is displayed. Generally, it is better to exit from the file menu or toolbox.

Note: Clicking **Interrupt** is equivalent to specifying the -SIGINT option on the kill command. Clicking **Terminate** is equivalent to specifying the -SIGTERM option on the kill command.

For more information about the SAS Session Manager, see “The SAS Session Manager (motifxsassm) in UNIX” on page 161.
Using the UNIX kill Command

Note: Use the kill command only after you have tried all other methods to exit your SAS session.

The kill command sends an interrupt or terminate signal to SAS, depending on which signal you specify. You can use the kill command to interrupt or terminate a SAS session running in any mode. The kill command cannot be issued from within a SAS session. You must issue it from another terminal or from another window (if your terminal permits it).

The format of the kill command is:

```
kill <signal-name> pid
```

To send the interrupt signal, specify -SIGINT. To send the terminate signal, specify -SIGTERM. Use the ps command and its options to determine the process identification number (pid) of the SAS session that you want to interrupt or terminate.

The results of using the ps command differ in different operating environments. See the UNIX man page for your operating environment for specific information about the ps command and its options. Adding options helps determine which process you want to kill if you have more than one SAS process running. Also, servers (metadata, OLAP, and so on) leave a process identification number in their start-up directories. You can use this number with the kill command.

The following table lists some of the important kill signals.

<table>
<thead>
<tr>
<th>Signal</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SIGNULL</td>
<td>Checks access to process identifier.</td>
</tr>
<tr>
<td>1</td>
<td>SIGHUP</td>
<td>Causes SAS to terminate.</td>
</tr>
<tr>
<td>2</td>
<td>SIGINT</td>
<td>Causes SAS to interrupt the session. SIGINT is very similar to SIGQUIT.</td>
</tr>
<tr>
<td>3</td>
<td>SIGQUIT</td>
<td>Causes a more forceful shutdown than SIGTERM. It does not cause a core dump.</td>
</tr>
<tr>
<td>9</td>
<td>SIGKILL</td>
<td>Brings down SAS. Use this option only after all attempts to exit SAS have failed. Using SIGKILL can cause data corruption.</td>
</tr>
<tr>
<td>15</td>
<td>SIGTERM</td>
<td>Causes SAS to terminate.</td>
</tr>
</tbody>
</table>
For more information, see the UNIX man pages for the `ps` and `kill` commands.

---

**Messages in the Console Log (STDOUT)**

If SAS encounters an error or warning condition when the SAS log is not available, then any messages that SAS issues are written to the console log. Normally, the SAS log is unavailable only early in SAS initialization and late in SAS termination.

If you are using the `-STDIO` option, the log is displayed in stderr, and the listing is displayed in stdout.

---

**Ending a Process That Is Running as a SAS Server**

If you need to end a process that is running as a SAS server, use one of the following methods:

- If you are using the SAS Metadata Server, use the SAS Management Console to end a process.
- If you are using another SAS server, use the UNIX scripts that shipped with the servers to stop the process. You can also use these scripts to start (or restart) a server, as well as determine whether the server is already running. For more information about these scripts, contact your site administrator.

Note: If the server does not respond to the UNIX script, then you can use the `kill` command to end the server process. For more information, see “Using the UNIX kill Command” on page 34.

---

**Interrupting a SAS Process and the Underlying DBMS Process**

**CAUTION**

Interrupting a SAS process and the underlying DBMS process might kill all jobs that are running on your DBMS. Interrupting a SAS or DBMS process should be an exception. Use care when you construct your queries. For example, if SAS sends SQL to an RDBMS, there is no way to interrupt the SQL statements because SAS no longer has control of them. The statements are running in the RDBMS.

When you interrupt a SAS process, you might terminate the current query. If you are using the current query to create a new data set, then the data set is still created.
even if the query is terminated. If you are using the current query to overwrite a data set, then the data set is not overwritten if the query is terminated. In most cases, you do not receive a warning that the query did not complete.

Note: In this section, SAS process refers to a series of events. It is not the process on the operating system. When you interrupt or terminate a SAS process, the process on the operating system might still be running.

In many cases (such as using Oracle in UNIX environments), when you interrupt or terminate a query on a server, the following processes stop:

- Processing of current extractions. For example, if you forgot to include a WHERE clause in your SQL query and are now extracting one billion rows into SAS, issuing an interrupt stops the SAS process and the extract step in the DBMS.

- Processing of queries that are in progress on the server. For example, you might have a very complex extract query that runs for a long time before producing a result. Issuing an interrupt stops the SAS and DBMS processes. As a result, the complex extract query running on your DBMS server is interrupted and terminated.

- Processing an update, delete, or insert. For example, you are updating, deleting, or inserting many rows in your DBMS. An interrupt stops the SAS and DBMS processes.
Connecting to the CAS Server

Overview of Connecting to the CAS Server

The following topics explain how to connect to the CAS server if you have both SAS 9.4 and SAS Viya on your system. There are some requirements that must be met before you can connect to the server from your SAS 9.4 session. These requirements also apply when you run a SAS program from the command line, such as when you run a program in batch mode or when you submit SAS commands in interactive line mode.

How to Connect to the CAS Server

Requirements to Connect to the CAS Server

Before you can submit a program that connects to the server, you must have permission to access the server. Your system administrator manages users and permissions.

In addition, the server must be running before your program can connect to it. Your system administrator typically manages the servers that are used by SAS.

To submit a program that connects to the server from the command line:

- If you attempt to connect to the CAS server, and you receive an error that the certificate is not trusted, then contact your SAS administrator. For information about obtaining and configuring certificates, see “Configure SAS 9.4 Clients to Work with SAS Viya”.

Example Program That Connects to the CAS Server:...
Create an authinfo file. You must have an authinfo file that provides your user ID and password for connecting to the server. For more information, see “Authinfo File Requirement” in SAS Viya: System Programming Guide.

Note: The actual filename of the authinfo file is .authinfo in a UNIX environment.

Specify the CAS server. You can provide this value with the HOST value in the authinfo file, or you can use the CASHOST= option in the OPTIONS statement.

Note: In SAS Studio for SAS Viya, the CAS server is set automatically and does not need to be specified. If you are running SAS 9.4, specify the CASHOST= option.

Specify the server port value. The default value for the server port is 5570. You can provide this value with the PORT value in the authinfo file, or you can use the CASPORT= option in the OPTIONS statement.

Note: In SAS Studio for SAS Viya, the CAS server port value is set automatically and does not need to be specified. If you are running SAS 9.4, specify the CASPORT= option.

Specify a “CAS Statement” in SAS Cloud Analytic Services: User’s Guide in your program to start your CAS session.

As a best practice, at the end of the program, specify the TERMINATE option in a CAS statement. For example, this statement ends the CAS session called mysess:

```sas
cas mysess terminate;
```

When you submit a program from the command line, such as when you submit a program at a scheduled time overnight, specify the CAS server value and CAS server port value. Otherwise, your program does not connect to the CAS server.

---

Example Program That Connects to the CAS Server

The following code connects to the CAS server:

```sas
/* These options must be included to connect to the CAS server in batch mode */
options cashost='host-name' casport=xxxxx;

cas casauto;
caslib _all_ assign;
proc cas;
  session casauto;

  /* Load source data (Cars) into a table in CAS */
  table.loadTable result=r /
    caslib="hps"
    path="carssashelp.sashdat"
    casOut={name="cars",replace=true};

  /* View variable information */
```

Comparison of Batch Modes and Interactive Modes

There are two methods of running a program in batch mode. One method is to submit a program from the command line without viewing it in an interface. The other is to submit the program from SAS Studio as a background submission. To do this, right-click on the program, and submit it without first opening it in the code editor.

Table 2.1  Comparison of Batch Mode from the Command Line or in SAS Studio

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the command line</td>
<td>Invoke the SAS command, and specify the program to submit. To submit the program mySASprog.sas from the command line, issue this command:</td>
</tr>
<tr>
<td></td>
<td><code>sas mySASprog</code></td>
</tr>
<tr>
<td></td>
<td>You can specify options in the invocation command:</td>
</tr>
<tr>
<td></td>
<td><code>sas -errors 10 mySASprog</code></td>
</tr>
<tr>
<td></td>
<td>The log and results are in separate files that begin with the name of the program that you are submitting. For example, if you submit the program mySASprog.sas, then the log and results are in the files mySASprog.log and mySASprog.lst, respectively.</td>
</tr>
</tbody>
</table>
## Method Description

**In SAS Studio (as a background submission)**

Right-click on the program in the navigation pane, and submit it to run in the background. This runs the program in SAS Studio without first opening it in the code editor.

The log and results appear in SAS Studio.

For more information, see Using the Background Submit Feature in SAS Studio: User’s Guide.

Introduction to SAS Files, Libraries, and Engines in UNIX Environments

SAS Files

What Is a SAS File?

Your data can reside in different types of files, including SAS files and files that are formatted by other software products, such as database management systems. Under UNIX, a SAS file is a specially structured UNIX file. Although the UNIX operating environment manages the file for SAS by storing it, the operating system cannot process it because of the structure built into the file by SAS. For example, you can list the filename with the `ls` command, but you cannot use the `vi` editor to edit the file. A SAS file can be permanent or temporary.

Case Sensitivity in Data Set Names

In UNIX operating environments, SAS data set names are written in all lowercase characters. Because of this requirement, SAS reads only data set names that are written in all lowercase characters.

If you use the UNIX utilities `mv` or `cp` to rename SAS data set names with uppercase or mixed-case characters, SAS can no longer read the data set names.

SAS Libraries and Librefs

SAS files are stored in SAS libraries. A SAS library is a collection of SAS files within a UNIX directory. Any UNIX directory can be used as a SAS library. (The directory can also contain files called external files that are not managed by SAS. See Chapter 4, "Using External Files and Devices," on page 79 for how to access external files.) SAS stores temporary SAS files in a Work library, which is automatically defined for you. You must specify a library for each permanent SAS file. For more information, see "Work Library" on page 69.

SAS libraries can be identified with librefs. A libref is a name by which you reference the directory in your application. For more information about how to assign a libref, see "Referring to SAS Files By Using Librefs in UNIX Environments" on page 57.

Engines

SAS files and SAS libraries are accessed through engines. An engine is a set of routines that SAS must use to access the files in the library. SAS can read from and,
in some cases, write to the file by using the engine that is appropriate for that file type. For some file types, you need to tell SAS which engine to use. For others, SAS automatically chooses the appropriate engine. The engine that is used to create a SAS data set determines the format of the file.

Additional Resources

For more information about SAS files, libraries, and engines, see SAS Language Reference: Concepts.

Common Types of SAS Files in UNIX Environments

SAS Data Sets

What Are SAS Data Sets?

SAS data sets fall into two categories:

- “SAS Data Sets (Member Type DATA)” on page 45
- “SAS Views (Member Type VIEW)” on page 45

Descriptor Information and Data Values

Data sets consist of descriptor information and data values organized as a table of rows and columns that can be processed by one of the SAS engines. The descriptor information includes data set type, data set label, the names and labels of the columns in the data set, and so on. A SAS data set can also include indexes for one or more columns.

SAS data sets are implemented in two forms:

- If the data values and the data set's descriptor information are stored in a file, then the file is a SAS data set.
- If the file contains information about where to obtain a data set's data values and descriptor information, then the file is a SAS view.

The default SAS engine processes the data set as if the data file or data view and the indexes were a single entity.

For more information, see “SAS Data Sets (Member Type DATA)” on page 45 and “SAS Views (Member Type VIEW)” on page 45.
SAS Data Sets (Member Type DATA)

The SAS data set is probably the most frequently used type of data file. These files have the extension `.sas7bdat`. SAS data sets are created in the DATA step and by some SAS procedures. SAS data sets store data values and their descriptor information in files formatted by SAS.

SAS data sets are created by the default SAS engine, and they can be indexed. An index is an auxiliary file created in addition to the data set it indexes. The index provides fast access to observations within a SAS data set by a variable or key. Under UNIX, indexes are stored as separate files, but are treated by SAS as an integral part of the SAS data set.

**CAUTION**

Do not remove index files using UNIX commands. Removing the index file can damage your SAS data set. Also, do not change its name or move it to a different directory. Use the DATASETS procedure to manage indexes.

SAS Views (Member Type VIEW)

A SAS view contains only the information needed to derive the data values and the descriptor information. SAS views contain information about data in one or more SAS data sets or SAS views. A SAS view is created with the SQL procedure or DATA step.

SAS Catalogs (Member Type CATALOG)

Catalogs are a special type of SAS file that can contain multiple entries. Many different types of entries can be kept in the same SAS catalog. For example, catalogs can contain entries created by SAS/AF and SAS/FSP software, windowing applications, key definitions, SAS/GRAPH graphs, and so on.

Catalogs have the SAS member type of CATALOG.

**Note:** Catalogs are not included in SAS Viya.

Stored Program Files

Stored program files are compiled DATA steps, and have the SAS member type of PROGRAM. For more information, see “Stored Compiled DATA Step Programs” in *SAS Language Reference: Concepts*.  

---

*Common Types of SAS Files in UNIX Environments*
File Extensions and Member Types in UNIX Environments

Because SAS needs to distinguish between the different file types, it automatically assigns an extension to each file when it creates the file. Also, because each SAS file is a member of a library, SAS assigns each file a member type.

The following table lists the file extensions and their corresponding SAS member types.

**CAUTION**
Do not change the file extensions of SAS files. File extensions determine how SAS accesses files; changing them can cause unpredictable results.

1 This file type is not included in SAS Viya.

A UNIX directory can store a variety of files, but you might find it more practical to store files in separate directories according to their use. Also, you can keep libraries that are accessed by different engines in the same directory, but this is not recommended. For more information, see “Using Multiple Engines for a Library in UNIX Environments” on page 64.

### How File Extension Delimiters Are Handled

If you reference a SAS file directly by its physical name, the final embedded period is an extension delimiter, regardless of the VALIDMEMNAME setting. Consequently, if you use the EXTEND option with VALIDMEMNAME= and the member name itself contains a period, then the full extension must be specified as part of the reference. For more information, see “VALIDMEMNAME= System Option” in SAS System Options: Reference.

The following example illustrates this concept. The comments in the example are from the SAS log:

```sas
options validmemname=extend;
libname mylib '.saslib';
    /* NOTE: Libref MYLIB was successfully assigned as follows: */
    /* Engine:       V9 */
    /* Physical Name: SAS-library */

data mylib."my.member"n;
x=1;
run;
    /* NOTE: The data set MYLIB.'MY.MEMBER'n has 1 observations */
    /* and 1 variables. */
```
Using Direct I/O

Introduction to Direct I/O

Direct I/O is a method for processing input and output files and is used in file handling. Direct I/O enables SAS to read files from and write files directly to storage devices without first going through the UNIX operating environment's read and write caches. You can use direct I/O for SAS files. Using direct I/O might improve system performance, depending on the number and types of jobs that you are running.

SAS uses three related options that affect direct I/O:

- **ENABLEDIRECTIO** statement option
- **USEDIRECTIO=** statement option
- **USEDIRECTIO=** data set option

The **ENABLEDIRECTIO** option in the LIBNAME statement makes direct I/O processing available for data sets that are listed in the DATA statement. The libref that points to the data sets must have been defined in a LIBNAME statement that uses the **ENABLEDIRECTIO** option. Using **ENABLEDIRECTIO** itself does not turn on direct I/O.

A libref that is assigned to a directory with the **ENABLEDIRECTIO** option will not match another libref that is assigned to the same directory without the **ENABLEDIRECTIO** option. The two librefs point to the same directory, but the files that are opened using the libref with **ENABLEDIRECTIO** can be read from and written to using direct I/O. Files that are opened using the other libref are read from and written to using the regular disk I/O calls.

The **USEDIRECTIO=** data set option in the DATA statement or the **USEDIRECTIO=** statement option in the LIBNAME statement turns on direct I/O for data sets in which the **ENABLEDIRECTIO** statement option has been applied. Using **USEDIRECTIO=** without first applying the **ENABLEDIRECTIO** option has no effect on direct I/O in a data set.
**Turning On Direct I/O**

You can turn on direct I/O in two ways:

1. Use both the ENABLEDIRECTIO and USEDIRECTIO= options in the LIBNAME statement.
   
   This method opens for direct I/O all of the files that are referenced by the libref in the LIBNAME statement.

2. Use the ENABLEDIRECTIO option in the LIBNAME statement to render direct I/O available, and use the USEDIRECTIO= data set option in a DATA statement to turn on direct I/O functionality.
   
   This method opens for direct I/O only the data set where the option is used. The data set must be referenced by the libref in the LIBNAME statement.

For more information about these options and how they are used, see:

- ENABLEDIRECTIO in "Engine and Host Options" on page 364
- USEDIRECTIO= in "Engine and Host Options" on page 364
- "USEDIRECTIO= Data Set Option: UNIX" on page 283

---

**Holding a File in Memory: The SASFILE Statement**

You can use the SASFILE statement to open a SAS data set. SAS attempts to allocate enough buffers to hold the entire data set in memory. If enough memory is available, then the entire data set is kept in memory until the data set is closed. If enough memory is not available, then SAS allocates as many buffers as it can. If your file is very large or if SAS is already using a large amount of memory, then using the SASFILE statement does not help.

**Note:** The SASFILE statement is not supported on the CAS server.

When the SASFILE statement executes the first time, SAS opens the file. Subsequent DATA and PROC steps use the file without having to open it again because the file remains in memory. The file remains open until a second SASFILE statement closes it, or until the program or session ends. For more information, see "SASFILE Statement" in SAS Global Statements: Reference.
Sharing SAS Files in a UNIX Environment

Sharing SAS Files

If more than one SAS process has Write access to a SAS file and both processes attempt to update the file at the same time, then the file is likely to be corrupted. For this reason, SAS locks the file to prevent more than one user from having Write access to a file. When one SAS process opens a file with Write access, other processes are blocked from Write access until the first process closes the file. SAS provides statement and system options to override this file protection. However, in almost all cases, you should leave file protection turned on.

Be aware that SAS uses the cooperative file locking mechanism that is provided by the operating system. This means that you can place a Write lock on a file in a SAS session. However, an external user can still modify or delete the file via a command in the operating system if the command does not honor cooperative locking.

Options to Use for File Locking: SAS Files

You can turn off file locking for SAS files in the following ways:

- Use the FILELOCKS option in the LIBNAME statement.
- Use the FILELOCKS system option.

File Locking for SAS Files: The FILELOCKS Statement Option

By default, SAS restricts Write access to one user. The FILELOCKS option in the LIBNAME statement overrides the default and allows multiple users to have Write access to a file. SAS files that are opened under the libref in the LIBNAME statement are the files that are locked. Multiple users have Read access to files.

**CAUTION**

Setting FILELOCKS=NONE in a LIBNAME statement can result in data corruption. If multiple users have Write access to a file, then simultaneous updates to the file can generate unpredictable results.

The FILELOCKS statement option applies to most (but not all) of the SAS I/O files (for example, data sets and catalogs) that are opened under the libref in the LIBNAME statement.

For more information, see “LIBNAME Statement: UNIX” on page 359.
File Locking for SAS Files: The FILELOCKS System Option

By default, SAS restricts Write access to one user. The FILELOCKS system option overrides this default for both SAS files and external files and allows multiple users to have Write access to a file. The FILELOCKS system option enables you to apply a behavior globally to individual files that are opened.

CAUTION
Setting FILELOCKS=NONE in a LIBNAME statement can result in data corruption. If multiple users have Write access to a file, then simultaneous updates to the file can generate unpredictable results.

You can use the FILELOCKS system option at start-up, in the OPTIONS statement, or in the command line. You can specify multiple instances of the FILELOCKS system option. Each instance is added to an internal table of paths and settings. The FILELOCKS system option applies to most (but not all) of the SAS I/O files (for example, data sets and catalogs) that are opened under the libref in the LIBNAME statement. For more information, see “FILELOCKS System Option: UNIX” on page 397 and “LIBNAME Statement: UNIX” on page 359.

Waiting to Use a Locked File

If you want to use a SAS file that is locked by another process, you can use the FILELOCKWAIT option in the LIBNAME statement to specify how long SAS waits for the locked file to become available. The FILELOCKWAIT statement option affects only those files that are opened under the libref in a LIBNAME statement. For more information, see “LIBNAME Statement: UNIX” on page 359.

Conditions to Check When FILELOCKS=NONE

When file locking is turned off (that is, when the FILELOCKS system option is set to NONE), SAS attempts to open a file without checking for an existing lock on the file. These files are not protected from shared Update access.

CAUTION
SAS recommends that you do not use the FILELOCKS=NONE option. If multiple users open the same file for Write access, then the file might become corrupted. The FILELOCKS=NONE option is used primarily to determine whether a job failed because of a locked file.

If the FILELOCKS system option is set to NONE, then you should perform one of the following tasks:

- Make sure that your sasuser directory is unique for each SAS session. Typically, the system administrator assigns this directory in the system configuration file. The specification in that file or in your personal configuration file helps ensure that the directory is unique as long as you run only one SAS session at a time.
If you run two or more SAS sessions simultaneously, you can guarantee unique user files by specifying different `sasuser` directories for each session. In the first session, you can invoke SAS with this option and value:

```
-sasuser ~/sasuser
```

In the n\textsuperscript{th} session, you can invoke SAS with this option and value:

```
-sasuser ~/sasuser\textsubscript{n}
```

For more information, see “Order of Precedence for Processing SAS Configuration Files” on page 27 and “RSASUSER System Option: UNIX” on page 434. The RSASUSER option can be used to control modifications to the Sasuser library when it is shared by several users (see “RSASUSER System Option: UNIX” on page 434.)

If you run two or more SAS sessions simultaneously, and you use the same Sasuser.Profile catalog, do not perform any actions within a SAS session to change the Sasuser.Profile catalog. This is because both SAS sessions can use the same catalog.

You can run two or more SAS sessions either by using the X statement or by invoking SAS from two different windows.

Actions such as using the WSAVE command or changing key assignments modify the Sasuser.Profile catalog.

Multiple users can read the same data sets at the same time. However, only one user at a time should write to or update a data set so that data is not overwritten or corrupted.

---

**When FILELOCKS=CONTINUE**

By default, SAS restricts Write access to one user. When you use the FILELOCKS=CONTINUE option, SAS fails to open a file if that file is locked by another user, and writes an error message to the log. However, if SAS returns a message that identifies some other error, then SAS disregards the lock on the file, opens the file, and continues to execute the job.

---

**Sharing Files over a Network**

**Introduction to Sharing Files on Multiple Workstations**

SAS can be licensed to run on one or more workstations in a network of similar computers. The license specifically lists the workstations on which SAS can run. Unlicensed workstations in the network might have access to the SAS executable files, but they might not be able to run SAS.

If the licensed workstations are connected through NFS mounts so that they share a file system, they can all share a single copy of the SAS executable files. However, sharing of a single copy is not necessary. They can also share SAS files. In contrast, if a SAS session opens a data set or catalog for update, it must obtain an exclusive file lock on that file to prevent other SAS sessions from accessing that file. Other SAS sessions are blocked from access as long as the file is open.
If SAS is installed on different types of workstations that are connected through NFS, then each type of workstation must have its own copy of the SAS executable files.

Accessing Files on Different Networks

You can access a file on a different type of workstation if the two computers are connected to the same file system. You can access external files that were created under a different operating environment.

If you create a data set or catalog and save it to a directory, and later want to access the file from another computer on a different network, you have several alternatives for working with that file:

- You can log on to a computer remotely and perform the work there if you rarely use the file.
- You can log on to a computer remotely and perform the work there if the file changes often. This alternative ensures that you are accessing the most current version of the file. If you use PROC CPORT to copy the file to your computer, the original file might have changed between the time it was copied and the time it was read.
- You can log on to a computer remotely rather than transfer the file to your computer if you want to use the file once. It might not be efficient to use PROC CPORT, or you might not have enough disk space for PROC CPORT to run locally.
- You can use the File Transfer Protocol (FTP) or the Routing Control Processor (RCP) to transfer the file from the remote computer to your computer.
- You can do part of your work on your computer and part of your work on a remote computer. One example of this alternative is to run a set of statements on a small test case on the local computer, and then submit the real work to be done on the remote computer. Similarly, you can subset a large data set on another computer and then do local analysis on that subset. You can accomplish this task by using SAS/CONNECT software. For more information about Remote Library Services, see *SAS/CONNECT User’s Guide*.

Troubleshooting: Accessing Data over NFS Mounts

SAS might hang when accessing data over NFS mounts if the FILELOCKS option is set to FAIL or CONTINUE. To alleviate the problem, ensure that all NFS file locking daemons are running on both computers (usually statd and lockd). Your UNIX system administrator can assist with starting statd and lockd.

**Note:** To test whether there is a problem with file locking, you can set the FILELOCKS system option to NONE temporarily. If setting FILELOCKS to NONE resolves the problem, then you know that there probably is a problem with the statd and lockd daemons. It is recommended that you do not set FILELOCKS to NONE permanently because it might cause data corruption or unpredictable results.
Migrating 32-Bit SAS Files to 64-Bit in UNIX Environments

What Is File Migration?

File migration moves libraries forward to a new release of SAS. In many cases, SAS files from previous releases or from other hosts are compatible with SAS 9.4. If the files are not compatible, you can use Cross-Environment Data Access (CEDA) to migrate your files and libraries. You can use PROC MIGRATE, a utility procedure, to streamline the process of moving files and libraries forward. When you migrate your files and libraries, consider the release of SAS in which your data currently resides, what member types exist in your libraries, and whether you must move members from 32-bit libraries to 64-bit libraries.

For information about using CEDA, see “Processing Data Using Cross-Environment Data Access (CEDA)” in SAS Language Reference: Concepts. For information about using the MIGRATE procedure, see “MIGRATE Procedure” in Base SAS Procedures Guide. For more information, see the SAS Technical Support site.

Benefits of Migrating SAS Files

Migrating SAS files enables you to do the following:

- have Update access to unsupported data files
- have access to indexes, integrity constraints, and other features
- use long names for formats and informats
- use more than 32,767 variables
- use suppressed transcoding of a specified variable
- avoid the overhead of reading or writing to 32-bit files in a 64-bit SAS session

How to Migrate a SAS Library in a Linux Environment

To migrate a SAS library, use the MIGRATE procedure. If you are migrating from a 32-bit Linux environment to a 64-bit Linux environment and catalogs exist in the library, you must have access to a 32-bit Release 9 SAS/CONNECT or SAS/SHARE server.

For information about using the MIGRATE procedure, see “MIGRATE Procedure” in Base SAS Procedures Guide. For more information, see the SAS Technical Support site.
Creating a SAS File to Use with an Earlier Release

The V9 engine differs slightly from previous SAS engines. The V9 engine supports longer format and informat names than previous SAS engines. For a discussion about how to ensure compatibility between releases, see *SAS Language Reference: Concepts*. For more information, see the SAS Technical Support site.

Reading SAS Files from Previous Releases or from Other Hosts

Reading Version 6 Files

Using the V6 Read-Only engine, SAS can read Release 6 data sets that were created by compatible computer types. In most cases, SAS invokes the V6 engine automatically, and you do not have to specify it. The following examples demonstrate how you can use the V6 engine:

- If you are running SAS 9.4 on Linux, you can use the V6 engine to read Release 6 data sets that were created with any Intel ABI release of SAS, such as SCO UNIX.
- If you are running SAS 9.4 on HP-UX, you can use the V6 engine to read Release 6 data sets that were created on HP-UX, Solaris, AIX, or IRIX.
- For more information about the compatibility of Release 6 files, see "Introduction to Cross-Release Compatibility and Migration" in *SAS Language Reference: Concepts*.

Reading Version 8 or Later Files from Compatible Computer Types

If your files were created in 64-bit SAS, they are compatible with SAS 9.4. You do not need to use CEDA to read your files.
Reading Version 8 or Later Files from Incompatible Computer Types

Compatibility of Existing SAS Files with SAS 9.4

In SAS 9, SAS for AIX, HP-UX, and Solaris environments is 64-bit only. Some SAS files that were created in 32-bit releases of SAS cannot be read by the V9 engine.

SAS automatically tries to use CEDA to read data sets. If you use CEDA to read a data set and include `msglevel=i` in your code, then SAS writes a note to the log.

The following table lists processing that is supported for each SAS file with CEDA.

**Table 3.2  Supported Processing for Release 8 32-Bit Files in SAS 9**

<table>
<thead>
<tr>
<th>File Type</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAS files</td>
<td>Input processing and output processing. (In SAS 9, if you create a new data file from the 32-bit file, the new file is generally 64-bit. For more information about CEDA, see “Processing Data Using Cross-Environment Data Access (CEDA)” in SAS Language Reference: Concepts. For more information, see the SAS Technical Support site.)</td>
</tr>
<tr>

<td>No support.</td>
</tr>
</tbody>
</table>

**Note:** In SAS 9, if you create a new data file from a 32-bit file, the new file is generally 64-bit. For information about CEDA, see “Processing Data Using Cross-Environment Data Access (CEDA)” in SAS Language Reference: Concepts. For more information, see the SAS Technical Support site.
Accessing Version 8 or Later Files with CEDA

CEDA enables a SAS data set that was created in Version 8 or later in any directory-based operating environment (such as UNIX and Windows) to be read by a SAS session that is running in another directory-based environment. In SAS 9.4, if you try to access a data set that was created in a previous release, then SAS automatically uses CEDA to process the file. For example, if you are running SAS 9.4 on Linux, SAS uses CEDA to process a data set that was created in Release 8 on a 64-bit Solaris host. With CEDA, you have Read and Write access to these files. However, the file cannot be updated. For more information, see the SAS Technical Support site.

For best system performance, it is better to use data sets that are in the native format. Otherwise, CEDA might require additional CPU resources and might reduce system performance.

If you need to access 32-bit SAS data sets, SAS/ACCESS views from Oracle or Sybase, SQL views, or MDDB files from a 64-bit SAS session, then you can access these files using CEDA. CEDA provides Read and Write access to these files. However, CEDA does not support Update processing. CEDA consumes additional resources each time you read or write to these files. For more information about CEDA, see “Processing Data Using Cross-Environment Data Access (CEDA)” in SAS Language Reference: Concepts.

Catalogs and other SAS files (not including SAS data sets) contain data structures that are known only to the application that created them. These catalogs and files might contain data objects other than character or numeric objects and therefore cannot be shared between 64-bit SAS and earlier 32-bit releases of SAS.

Referring to SAS Files By Using Librefs in UNIX Environments

Techniques for Referring to a SAS File

If you want to read or write to a permanent SAS file, you can refer to the SAS file in one of two ways:

- Refer to the data file directly by using its pathname in the appropriate statements (such as DATA, SET, MERGE, UPDATE, OUTPUT, and PROC).
- Assign a libref to the SAS library (directory) that contains the data file and use the libref as the first level of a two-level filename.

What Is a Libref?

A libref is an alias that you can use to refer to the library during a SAS session or job. You will probably want to use a libref when one of the following is true:
The data file pathname is long and must be specified several times within a program.

The pathname might change. If the pathname changes, you need to change only the statement assigning the libref, not every reference to the file.

Your application will be used on other platforms. Using librefs makes it easier to port an application to other operating environments.

You need to concatenate libraries. For more information, see “Assigning a Libref to Several Directories (Concatenating Directories) in UNIX” on page 62.

Librefs can be stored in the SAS registry. For more information, see “Customizing Your SAS Registry Files” on page 20.

Assigning Librefs

Methods for Assigning Librefs

You can use any of the following items to assign a SAS libref:

- LIBNAME statement
- LIBNAME function
- DMLIBASSIGN command in the SAS windowing environment
- LIBNAME window in the SAS windowing environment
- SAS Explorer window in the SAS windowing environment

A libref assignment remains in effect for the duration of the SAS job, session, or process unless you clear the libref or use the same libref in another LIBNAME statement or LIBNAME function.

If you assign a libref from a SAS process, that libref is valid only within that SAS process. If you clear a libref from within a SAS process, that libref is not cleared from other SAS processes.

Using the LIBNAME Statement

The LIBNAME statement identifies a SAS library to SAS, associates an engine with the library, enables you to specify options for the library, and assigns a libref to it. For information about LIBNAME statement syntax, see “LIBNAME Statement: UNIX” on page 359.

Using the LIBNAME Function

The LIBNAME function takes the same arguments and options as the LIBNAME statement. For more information about the LIBNAME function, see “LIBNAME Function” in SAS Functions and CALL Routines: Reference.
Using the DMLIBASSIGN Command

Note: This method does not support adding a CAS libref.

Perform the following steps to assign a libref using the DMLIBASSIGN command in the SAS windowing environment:

1. Issue the DMLIBASSIGN command in the command window.
   The New Library dialog box appears.

2. Specify the libref in the Name field.

3. Specify an engine for the libref in the Engine field by selecting the default engine or another engine from the menu. Depending on the engine that you select, the fields in the Library Information area might change.

4. Click Enable at startup to assign this libref when you invoke SAS.

5. Specify the necessary information for the SAS library in the Library Information area. Depending on the engine that you select, there might not be a Path field available for input.

6. Specify LIBNAME options in the Options field. These options can be specific to your host or engine, including options that are specific to a SAS engine that accesses another software vendor's relational database system.

7. Click OK.

Using the LIBNAME Window

Note: This method does not support adding a CAS libref.

Perform the following steps to assign a libref from the LIBNAME window in SAS windowing environment:

1. Issue the LIBNAME command in the command window.
   The LIBNAME window appears.

2. From the File menu, select New.
   The New Library dialog box appears.

3. Complete the fields in the New Library dialog box as described in "Using the DMLIBASSIGN Command" on page 59.

4. Click OK.

Using the SAS Explorer Window

Note: This method does not support adding a libref to the CAS engine.
Perform the following steps to assign a libref from the SAS Explorer window in the SAS windowing environment:

1. From the **File** menu, select **New** when the **Libraries** node in the tree structure is active.
   
The New dialog box appears.

2. Select **Library**, and then click **OK**.
   
The New Library dialog box appears.

3. Complete the fields in the New Library dialog box as described in “Using the DMLIBASSIGN Command” on page 59.

4. Click **OK**.

---

**Permanently Assigning a Libref**

You might want to save a libref so that it is valid between SAS sessions. You can assign a libref permanently by using one of the following methods:

- Specify the LIBNAME statement or LIBNAME function in an autoexec file. For more information, see “LIBNAME Function” in *SAS Functions and CALL Routines: Reference* or “LIBNAME Statement: UNIX” on page 359.

- Select **Enable at startup** when you assign a libref using the DMLIBASSIGN command, LIBNAME window, or SAS Explorer window. Selecting this option saves the libref in the SAS registry. For more information about these methods, see “Assigning Librefs” on page 58.

- Use environment variables as librefs. Include these environment variables in your start-up files so that these variables are set when SAS is invoked.

---

**Accessing a Permanent SAS Library By Using a Libref**

After you have defined a libref, you can use the libref in one of two ways to access a permanent SAS library:

- as the first level of a two-level SAS filename:

  `libref.member-name`

  Here `libref` is the first-level name referring to the directory where the file is stored, and `member-name` is the name of the file being read or created.

- as the value of the USER= option. (For more information, see “Using One-Level Names to Access Permanent Files (User Library)” on page 70.)

For example, these SAS statements access the data file Final.sas7bdat in the Sales library that is stored in the `/users/myid/mydir` directory:

```
libname sales '/users/myid/mydir';
data sales.final;
```
Specifying Pathnames in UNIX Environments

Rules for Specifying Directory and Pathnames

Whether you specify a data filename directly in the various SAS statements or you specify the library name in a LIBNAME statement, the same rules apply for specifying UNIX directory and file pathnames.

Specify directory and file pathnames in quotation marks. The level of specification depends on your current directory.

Example 1: Access a File That Is Not in the Current Directory

If `/u/2011/budgets` is not your current directory, then to access the data file named May, you must specify the entire pathname:

```
data '/u/2011/budgets/may';
```

If you wanted to use a libref, you might specify these statements:

```
libname budgets '/u/2011/budgets';
data budgets.may;
```

Example 2: Access a File in the Current Directory

If `/u/2011/budgets` is your current directory, you could specify only the filenames:

```
data 'quarter1';
   merge 'jan' 'feb' 'mar';
run;
```

Note: If you omit the quotation marks, then SAS assumes that these data sets are stored in the Work directory.

If you wanted to use a libref, then you might specify these statements:

```
libname budgets '.';
data budgets.quarter1;
   merge budgets.jan budgets.feb budgets.mar;
run;
```
Valid Character Substitutions in Pathnames

You can use the character substitutions in the following table to specify pathnames.

**Table 3.3  Character Substitutions in Pathnames**

<table>
<thead>
<tr>
<th>Characters</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>~/</td>
<td>$HOME/</td>
</tr>
<tr>
<td></td>
<td>Can be used only at the beginning of a pathname.</td>
</tr>
<tr>
<td>~name/</td>
<td>name's home directory (taken from file <code>/etc/passwd</code>). Can be used only at the beginning of a pathname.</td>
</tr>
<tr>
<td>!sasroot</td>
<td>name of sasroot directory (see Appendix 1, “The !SASROOT Directory,” on page 521.) Specified only at the beginning of a pathname.</td>
</tr>
<tr>
<td>.</td>
<td>current working directory.</td>
</tr>
<tr>
<td>..</td>
<td>parent of current working directory.</td>
</tr>
<tr>
<td>$VARIABLE</td>
<td>environment variable VARIABLE.</td>
</tr>
</tbody>
</table>

Assigning a Libref to Several Directories (Concatenating Directories) in UNIX

**Introduction to Concatenating Directories**

You can use the LIBNAME statement to assign librefs and engines to one or more directories, including the Work directory.

If you have SAS data sets located in multiple directories, you can treat these directories as a single SAS library by specifying a single libref and concatenating the directory locations. Here is an example:

```
libname income ('/u/2011/revenue', '/u/2011/costs');
```

This statement indicates that the two directories, /u/2011/revenue and /u/2011/costs, are to be treated as a single SAS library.

If you have already assigned librefs to your SAS libraries, you can use these librefs to indicate that you want to concatenate the libraries, as in this example:
libname income ('/u/2011/corpsale', '/u/2011/retail');
libname costs ('/u/2011/salaries', '/u/2011/expenses');
libname profits (income, costs, '/u/2011/capgain');

This statement indicates that the five directories, /u/2011/corpsale, /u/2011/retail, /u/2011/salaries, /u/2011/expenses, and /u/2011/capgain, are to be treated as a single SAS library.

How SAS Accesses Concatenated Libraries
When you concatenate SAS libraries, SAS uses a protocol for accessing the libraries, which depends on whether you are accessing the libraries for read, write, or update.

SAS uses the protocol in the following sections to determine which directory is accessed. The protocol illustrated by these examples applies to all SAS statements and procedures that access SAS files. These include the DATA, UPDATE, and MODIFY statements in the DATA step and the SQL and APPEND procedures.

Accessing Files for Input and Update
When a SAS data set is accessed for input or update, the first SAS data set that is found by that name is the one that is accessed. For example, if you submit the following statements and the data set old.species exists in both directories, the one in the mysasdir directory is the one that is printed:

```
libname old ('mysasdir','saslib');
proc print data=old.species;
run;
```

The same would be true if you opened old.species for update with the FSEDIT procedure.

Accessing Files for Output
If the data set is accessed for output, it is always written to the first directory, provided that the directory exists. If the directory does not exist, an error message is displayed. For example, if you submit the following statements, SAS writes the old.species data set to the first directory (mysasdir), and replaces any existing data set with the same name:

```
libname old ('mysasdir','saslib');
data old.species;
  x=1;
  y=2;
run;
```

If a copy of the old.species data set exists in the second directory, it is not replaced.
Accessing Data Sets with the Same Name

If you use the DATA and SET statements to access data sets with the same name, the DATA statement uses the output rules and the SET statement uses the input rules. When you execute the following statements, assume that `test.species` originally exists only in the second directory, `mysasdir`. Execute the following statements:

```sas
libname test ('sas','mysasdir');
data test.species;
set test.species;
if value1='y' then
  value2=3;
run;
```

The DATA statement opens `test.species` for output according to the output rules. That is, SAS opens a data set in the first of the concatenated libraries (`sas`). The SET statement opens the existing `test.species` data set in the second directory (`mysasdir`), according to the input rules. Therefore, the original `test.species` data set is not updated. After the DATA step executes, two `test.species` data sets exist, one in each directory.

Using Multiple Engines for a Library in UNIX Environments

You can assign multiple librefs to a single directory, and specify a different engine with each libref. For example, after the following statements are executed, data sets that are referenced by `one` are created and accessed using the default engine. Data sets that are referenced by `two` are created and accessed using the sequential engine:

```sas
libname one v9 '/users/myid/educ';
libname two v8 '/users/myid/educ';
```

**Note:** Keeping different types of libraries in one directory is not recommended because you must remember the appropriate engine for accessing each library. SAS cannot determine the right engine for accessing libraries in a directory that contains libraries of different types. For more information, see "Omitting Engine Names from the LIBNAME Statement" on page 363.
Using Environment Variables as Librefs in UNIX Environments

An environment variable can be used as a libref. The variable name must be in all uppercase characters, and the variable value must be the full pathname of the directory. That is, the name of the directory must begin with a slash.

Note: SAS on UNIX does not support the assignment of the User libref using the USER environment variable.

Supposed that you want to use the library in /users/mydir/educ, and you want to refer to it with the EDUC environment variable. You can define the variable at the following times:

- Before you invoke SAS. See “Defining Environment Variables in UNIX Environments” on page 285. For example, in the Korn shell, you might use this command:

  ```bash
  export EDUC=/users/mydir/educ
  ```

- After you invoke SAS. You can use the X statement (see “Executing Operating System Commands from Your SAS Session” on page 17) and the SAS setenv command:

  ```bash
  x setenv EDUC /users/mydir/educ;
  ```

You cannot specify an engine when you define a libref as an environment variable, so SAS determines which engine to use as described in “Omitting Engine Names from the LIBNAME Statement” on page 363.

After the libref is defined, you can use it to access data sets stored in the library:

```sas
proc print data=educ.class;
run;
```

Note: If a variable and a libref have the same name, but refer to different libraries, SAS uses the libref.

Librefs Assigned by SAS in UNIX Environments

SAS automatically defines three librefs:

**Sashelp**

contains a group of catalogs that contain information that is used to control various aspects of your SAS session. The Sashelp library is in the !SASROOT directory. For more information, see Appendix 1, “The !SASROOT Directory,” on page 521.
Sasuser contains SAS catalogs that enable you to customize features of SAS (such as window size, font settings, and printer entries) for your needs. If the defaults in the Sashelp library are not suitable for your applications, you can modify them and store your personalized defaults in your Sasuser library.

Work is the temporary, or scratch, library automatically defined by SAS at the beginning of each SAS session or job. The Work library stores two types of temporary files: those files that you create, and those files that are created internally by SAS as part of normal processing.

These librefs and the library libref are reserved librefs. If your site also has SAS/GRAPH software, the maps libref might be automatically defined. For more information about all of these libraries, see “Permanent and Temporary Libraries” in SAS Language Reference: Concepts. Sasuser and Work have operating system dependencies.

## Sasuser Library

### What Is the Sasuser Library?

The Sasuser library contains the customizations (such as window size and positioning, colors, fonts, and printer entries) that you specified for your SAS session. When you invoke SAS, it looks for the Sasuser directory to find these customizations. If this directory does not exist, SAS uses the SASUSER system option to create it. The default directory is set in the system configuration file (sasv9.cfg) and is usually similar to the following:

```
-sasuser ~/sasuser.v94
```

This specification tells SAS to create a directory for the Sasuser libref in your home directory. To determine the value of this directory for your system, use PROC OPTIONS or libname sasuser LIST.

You can permit Read-Only access to the Sasuser library by using the RSASUSER system option. For information about the SASUSER and RSASUSER system options, see “SASUSER System Option: UNIX” on page 442 and “RSASUSER System Option: UNIX” on page 434.

After the Sasuser library has been created, SAS automatically assigns the same Sasuser libref to it each time you start a SAS session. It cannot be cleared or reassigned during a SAS session. If you delete the library, SAS re-creates it the next time you start a session. Because SAS assigns the libref for you, you do not need to use a LIBNAME statement before referencing this library.

### Contents of the Sasuser Library

Your customizations are stored in one of the following locations in the Sasuser library:
Overview of the Sasuser.Profile Catalog

The Sasuser.Profile catalog is the profile.sas7bcat file in your Sasuser library. This catalog enables you to customize how you work with SAS. SAS uses this catalog to store function key definitions, fonts for graphics applications, window attributes, and other information from interactive windowing procedures. SAS saves changes that you make to function key definitions, window attributes (such as size, color, and position), PMENU settings, and so on, in the Sasuser.Profile catalog. The information in the Sasuser.Profile catalog is accessed automatically by SAS when you need it for processing.

Note: The Sasuser.Profile catalog is not included in SAS Viya.

How SAS Accesses the Sasuser.Profile Catalog

SAS creates the Sasuser.Profile catalog the first time it tries to find it and it does not exist. If you are using an interactive windowing environment, then creating the Sasuser.Profile catalog occurs during system initialization in your first SAS session. If you are using one of the other modes of execution, the Sasuser.Profile catalog is created the first time you execute a SAS procedure that requires it.

When the Sasuser.Profile Catalog Does Not Exist

If the Sasuser.Profile catalog does not exist, then, at invocation, SAS checks for the Sashelp.Profile catalog. (This catalog exists only if you have copied your Sasuser.Profile catalog to the Sashelp library.) If the Sashelp.Profile catalog exists, then SAS copies it to the Sasuser library, and this catalog becomes your new Sasuser.Profile catalog. If the Sashelp.Profile catalog does not exist, then SAS creates Sasuser.Profile using the default settings for a SAS session. The default settings for your SAS session are stored in several catalogs in the Sashelp library. If you make changes to key settings or other options, then the new information is stored in your Sasuser.Profile catalog. To restore the original default settings to the Sasuser.Profile catalog, use the CATALOG procedure or the CATALOG window to delete entries from your Sasuser.Profile catalog. By default, SAS then uses the corresponding entry from the Sashelp library.

Checking for an Uncorrupted Sasuser.Profile Catalog

When you invoke SAS, SAS checks for an existing, uncorrupted Sasuser.Profile catalog. If the catalog is found, SAS copies the Sasuser.Profile catalog to Sasuser.Profbak. This backup catalog is used if Sasuser.Profile becomes corrupted.
If you invoke SAS and determine that your customizations have been lost, then your Sasuser.Profile catalog is either corrupted or locked by another SAS session that was started with the same user ID. If either of these conditions are true, then SAS uses Sashelp.Profile or Sasuser.Profbak to replace the locked or corrupted Sasuser.Profile catalog.

If Your Sasuser.Profile Catalog Is Locked or Corrupted

If your Sasuser.Profile catalog is locked, then SAS checks for Sashelp.Profile. If Sashelp.Profile exists, SAS copies it to Work.Profile, and then saves the customizations to the Work.Profile catalog instead of the Sasuser(Profile catalog. This Work.Profile catalog is used for the duration of the SAS session. Because the contents of the Work directory are temporary, any customizations that you save to the Work.Profile catalog are lost at the end of the SAS session.

If your Sasuser.Profile catalog is corrupted, SAS copies the corrupted catalog to Sasuser.Badpro.SAS, and then checks for Sasuser.Profbak. If Sasuser.Profbak exists, then SAS copies it to Sasuser.Profile. Any changes that you made to the Sasuser.Profile catalog during the previous session are lost. If your Sasuser.Profile catalog is being used by multiple SAS sessions, then you can specify the RSASUSER system option to permit Read-Only access to the Sasuser library. Because this permission is Read-Only, you will not be able to save any customizations to your Sasuser.Profile catalog during that SAS session.

For more information about the Sasuser.Profile catalog and its related catalogs, as well as information about recovering locked or corrupted profile catalogs, see “SAS Catalogs” in SAS Language Reference: Concepts.

Sasuser.Registry Catalog

Overview of the Sasuser.Registry Catalog

The Sasuser.Registry catalog is the regstry.sas7bitm file in your Sasuser library. If you change any Universal Printing entries or libref assignments during a SAS session, then SAS saves the changes in the Sasuser.Registry catalog.

How SAS Accesses the Sasuser.Registry Catalog

At invocation, SAS looks in the Sasuser directory to see whether it can write to the Sasuser.Registry catalog. If SAS cannot write to this catalog, then the following warning appears in the SAS log:

```
WARNING: Unable to open SASUSER.REGISTRY. WORK.REGISTRY will be used instead.
NOTE: All registry changes will be lost at the end of the session.
```

If SAS can read the Sasuser.Registry catalog, then SAS copies the Sasuser.Registry catalog to create a Work.Registry catalog (in the Work library). This Work.Registry catalog is used for the duration of the SAS session. Because the contents of the Work library are temporary, any customizations that you save to the Work.Registry catalog are lost at the end of the SAS session. However, the customizations saved in the Sasuser.Registry catalog still exist.
If SAS cannot read the Sasuser.Registry catalog, then SAS creates the Work.Registry catalog using the default settings for a SAS session. In this case, SAS issues an additional warning to the SAS log:

```
WARNING: Unable to copy SASUSER.REGISTRY to WORK.REGISTRY.
```

### Sasuser.Prefs File

The settings that you specify in the Preferences dialog box (with the exception of resources on the General tab) are saved in the Sasuser.Prefs file. For more information about these resources, see "Modifying X Resources through the Preferences Dialog Box" on page 189.

**Note:** The Sasuser.Prefs file is not valid in SAS Viya.

---

### Work Library

The Work library is the temporary library that is automatically defined by SAS at the beginning of each SAS session or job. The Work library stores temporary SAS files that you create, as well as files created internally by SAS.

To access files in the Work library, specify a one-level name for the file. The libref Work is automatically assigned to these files unless you have assigned the User libref.

When you invoke SAS, it assigns the Work libref to a subdirectory of the directory specified in the WORK system option described in "WORK System Option: UNIX" on page 462. This subdirectory is usually named `SAS_workcode_nodename`, and has the following characteristics:

- **workcode**
  - is a 12-character code. The first four characters are randomly generated numbers. The next eight characters are based on the hexadecimal process identification number of the SAS session.

- **nodename**
  - is the name of the UNIX computer where the SAS process is running.

This libref cannot be cleared or reassigned during a SAS session.

The WORKINIT and WORKTERM system options control the creation and deletion of the Work library. For more information, see "WORKINIT System Option" in SAS System Options: Reference and "WORKTERM System Option" in SAS System Options: Reference.

**Note:** If a SAS session is terminated improperly (for example, with the `kill -9` command), SAS does not delete the `SAS_workcode_nodename` directory. You might want to use the `cleanwork` command to delete the directories.
Multiple Work Directories

SAS can make the distribution of Work libraries dynamic by distributing Work libraries across several directories. This functionality eliminates the potential problem of filling up a single volume with all of the Work directories.

The WORK system option contains the PATHNAME argument, which can be a directory, or a file that contains a list of directories, that SAS can use for allocating Work libraries. Individual Work libraries still reside in a single directory. You can use the WORK system option in a configuration file or in the command line.

When the argument to WORK is a list of directories in a file, you can specify a method for choosing which directory to use for WORK. If you specify METHOD=RANDOM, then SAS chooses at random a directory from the list of available directories. If you choose METHOD=SPACE, then SAS chooses the directory that has the most available space.

For more information, see “WORK System Option: UNIX” on page 462.

Using One-Level Names to Access Permanent Files (User Library)

Introduction to One-Level Names

SAS data sets are referenced with a one- or two-level name. The two-level name has the form \texttt{libref.member-name}, where \texttt{libref} refers to the SAS library in which the data set resides, and \texttt{member-name} refers to the particular member within that library. The one-level name has the form \texttt{member-name} (without a \texttt{libref}). In this case, SAS stores the files in the temporary Work library. To override this action and store files with one-level names in a permanent library, you must first assign the User libref to an existing directory. To refer to temporary SAS files while User is assigned, use a two-level name with WORK as the libref.

Techniques for Assigning the User Libref

You have three ways to assign the User libref:

- Assign the User libref directly using the LIBNAME statement:
  
  \begin{verbatim}
  libname user '/users/myid/mydir';
  \end{verbatim}

- Specify the USER= system option before you start the SAS session. For example, you can assign the User libref when you invoke SAS:
Specify the USER= system option after you start the SAS session. First, assign a libref to the permanent library. Then, use the USER= system option in an OPTIONS statement to equate that libref to User. For example, these statements assign the libref User to the directory with libref mine:

```
libname mine '/users/myid/mydir';
options user=mine;
```

For information about the USER system option, see "USER System Option: UNIX" on page 460.

**Note:** SAS on UNIX does not support the assignment of the User libref using the USER environment variable.

---

### Accessing Disk-Format Libraries in UNIX Environments

You probably create and access libraries on disk more than any other type of library. The default engine and the compatibility engines allow Read, Write, and Update access to SAS files on disk. They also support indexing and compression of observations.

In the following example, the In libref is assigned to a directory that contains the Stats1 data set:

```
libname in '/users/myid/myappl';
proc print data=in.stats1;
run;
```

Remember, either a SAS-data-library must exist or you must specify the DLCREATEDIR system option before SAS can read from or write to this directory. If DLCREATEDIR is specified and you refer to a directory that does not exist, SAS creates the directory. If DLCREATEDIR is not specified, then you first need to create the directory. For example, to create the SAS data set Orders in a new directory, use the X statement to issue the mkdir UNIX command. Then, you can use the LIBNAME statement to associate the libref with the new directory:

```
x mkdir /users/publish/books;
libname books '/users/publish/books';
data books.orders;
   ... more SAS statements ...
run;
```

By default, the LIBNAME statement associates the V9 engine with the directory.
Accessing Sequential-Format Libraries in UNIX Environments

Benefits and Limitations of Sequential Engines

The sequential engines enable you to access libraries in sequential format on disk. The sequential engines do not support indexing and compression of observations.

Note: Before using sequential engines, read the information about sequential libraries in “Sequential Data Libraries” in SAS Language Reference: Concepts.

Writing Sequential Data Sets to Named Pipes

Why Use Named Pipes?

You can send output to and read input from the operating environment by using named pipes. For example, you might want to compress a data set or send it to a sequential access management system without creating intermediate files.

Syntax of the LIBNAME Statement

You can read from and write to named pipes from within your SAS session by specifying the pipe name in the LIBNAME statement:

LIBNAME libref 'pipename';

Because you cannot position a pipe file, SAS uses a sequential engine to ensure sequential access. You do not have to specify the engine name.

Example: Creating a SAS Data Set Using a Named Pipe

To create a SAS data set and compress the data set without creating an intermediate, uncompressed data set, create a named pipe (such as mypipe) and enter the compress command:

    mkfifo mypipe; compress <mypipe >sasds.Z

In your SAS session, assign a libref to the pipe and begin writing to the data set:

    libname x 'mypipe';
    data x.a;
    ...more SAS statements...
    output;
    run;
The data is sent to `mypipe` and then compressed and written to the data set. When SAS closes the data set, compression finishes, and you have a compressed, sequential data set in `sasds.Z`.

If you begin writing to a named pipe before the task on the other end (in this case, the `compress` command) begins reading, then your SAS session is suspended until the task begins to read.

---

Accessing BMDP, OSIRIS, or SPSS Files in UNIX Environments

Introduction to the BMDP, OSIRIS, and SPSS Files

SAS includes three interface library engines, BMDP, OSIRIS, and SPSS, that enable you to access external data directly from a SAS program. All of these engines are read-only.

Because they are sequential, these engines cannot be used with the `POINT=` option in the `SET` statement, or with the `FSBROWSE`, `FSEDIT`, or `FSVIEW` procedures. You can use `PROC COPY`, `PROC DATASETS`, or a `DATA` step to copy a BMDP or OSIRIS system file or an SPSS export file to a SAS data set. Also, some procedures (such as `PROC PRINT`) give a warning message about the engine being sequential.

With these engines, the physical filename that is associated with a libref is an actual filename, not a directory. This association is an exception to the rules concerning librefs.

You can use the `CONVERT` procedure to convert BMDP, OSIRIS, and SPSS files to SAS files. For more information, see Chapter 25, “CONVERT Procedure,” on page 481.

The BMDP Engine

What Is the BMDP Engine?

The BMDP interface library engine enables you to read BMDP files from the BMDP statistical software application directly from a SAS program. The BMDP engine is a read-only engine. The following discussion assumes that you are familiar with the BMDP save file terminology. For more information, see the documentation that is provided by BMDP Statistical Solutions on the website.

Note: This engine is available for AIX, HP-UX, and Solaris.
Syntax for Accessing BMDP Save Files

To read a BMDP save file, issue a LIBNAME statement that explicitly specifies the BMDP engine. In this case, the LIBNAME statement has the following form:

```
LIBNAME libref BMDP 'filename';
```

This is a description of the arguments:

- `libref` specifies a SAS libref.
- `filename` specifies a BMDP physical filename.

**Note:** If the libref appears previously as a fileref, omit `filename` because SAS uses the physical filename that is associated with the fileref.

This engine can read save files that are created only on UNIX.

Because a single physical file can contain multiple save files, you reference the CODE= value as the member name of the data set within the SAS language. For example, if the save file contains CODE=ABC and CODE=DEF, and the libref is MyLib, you reference the files as MyLib.ABC and MyLib.DEF. All CONTENT types are treated the same. Even if member DEF has the value CONTENT=CORR, it is treated as if the value was CONTENT=DATA.

If you know that you want to access the first save file in the physical file or if there is only one save file, refer to the member name as _FIRST_. This reference is convenient if you do not know the CODE= value.

**Example: BMDP Engine**

Assume that the physical file mybmdp.dat contains the save file ABC. The following SAS code associates the libref Mylib with the BMDP physical file and executes the CONTENTS and PRINT procedures on the save file:

```
libname mylib bmdp 'mybmdp.dat';
proc contents data=mylib.abc;
run;

proc print data=mylib.abc;
run;
```

The following example uses the LIBNAME statement to associate the libref mylib2 with the BMDP physical file. Then, it writes the data for the first save file in the physical file:

```
libname mylib2 bmdp 'mybmdp.dat';
proc print data=mylib2._first_; 
run;
```
The OSIRIS Engine

What Is the OSIRIS Engine?

The Inter-University Consortium for Political and Social Research (ICPSR) uses the OSIRIS file format for distribution of its data files. SAS provides the OSIRIS interface library engine to support the many users of the ICPSR data and to be compatible with PROC CONVERT.

With the OSIRIS engine, you can read OSIRIS data and dictionary files directly from a SAS program. The following discussion assumes that you are familiar with the OSIRIS file terminology and structure. If you are not familiar with OSIRIS, see the documentation provided by ICPSR.

Notes about the OSIRIS Data Dictionary Files

Because OSIRIS software does not run outside the z/OS environment, the layout of an OSIRIS data dictionary is consistent across operating environments. However, the OSIRIS engine is designed to accept a data dictionary from any other operating environment on which SAS runs. It is important that the dictionary and data files not be converted from EBCDIC to ASCII; the engine expects EBCDIC data.

The dictionary file should consist of fixed-length records of length 80. The data file should contain records that are large enough to hold the data that is described in the dictionary.

Syntax for Accessing an OSIRIS File

To read an OSIRIS file, issue a LIBNAME statement that explicitly specifies the OSIRIS engine. In this case, the syntax of the LIBNAME statement has the following form:

```
LIBNAME libref OSIRIS 'data-filename' DICT='dictionary-filename';
```

This is a description of the arguments:

- `libref` specifies a SAS libref.
- `'data-filename'` specifies the physical filename of the data file.
  
  If the libref appears also as a fileref, omit `data-filename`.
- `DICT='dictionary-filename'` specifies the physical filename of the dictionary file. If `dictionary-filename` is an environment variable or a fileref, do not enclose it in quotation marks. The `DICT=` option is required.

OSIRIS data files do not have member names. Therefore, use whatever member name you want.

To use the same dictionary file with different data files, use a separate LIBNAME statement for each one.
Example: OSIRIS Engine

In the following example, the data file is /users/myid/osr/dat, and the dictionary file is /users/myid/osr/dic. The example associates the libref Mylib with the OSIRIS files, and executes the CONTENTS procedure and the PRINT procedure:

```sas
libname mylib osiris '/users/myid/osr/dat'
  dict='/users/myid/osr/dic';
proc contents data=mylib._first_
  run;
proc print data=mylib._first_
  run;
```

The SPSS Engine

What Is the SPSS Engine?

The SPSS engine is a read-only engine. With the SPSS interface library engine, you can read only SPSS export files. This engine does not read SPSS-X native files.

Syntax for Accessing an SPSS Export File

To read an SPSS export file, issue a LIBNAME statement that explicitly specifies the SPSS engine. In this case, the syntax of the LIBNAME statement has the following form:

```
LIBNAME libref SPSS 'filename';
```

This is a description of the arguments:

- `libref` specifies a SAS libref.
- `'filename'` specifies the physical filename.

**Note:** If the libref appears also as a fileref, omit `filename` because SAS uses the physical filename that is associated with the fileref.

Export files must be created by the SPSS EXPORT command and can originate from any operating environment. Export files must be transported to and from your operating environment in ASCII format. If they are transported in binary format, other operating environments are not able to read them.

Because SPSS-X files do not have internal names, refer to them by any member name that you like. A common extension for export files is .por, but this extension is not required.

SPSS can have system-missing and user-defined missing data. When you use the SPSS engine or PROC CONVERT, the missing values (user-defined or system-missing) are converted to system-missing values. User-defined missing values have to be recoded as valid values. When the data set is converted, you can use PROC FORMAT to make the translation (for example, -1 to .A and -2 to .B).
Reformatting SPSS Files

SAS cannot use an SPSS file that contains a variable with a numeric format that has a larger number of decimal places than the width of the entire variable. For example, if an SPSS file has a variable with a width of 17 and has 35 decimal places, SAS returns errors when you try to run a DATA step on the file or view it with the table viewer. To use the SPSS file with SAS, you have to reformat the variable.

You can reformat the variable by reducing the number of decimal spaces to a value that fits within the width of the variable. In the following example, the statement
\[
\text{revision=cat(\text{format,formatl,'}\cdot.2'));}
\]
converts the number of decimal spaces to 2. This value reduces the number of decimal spaces so that the number is not greater than the width of the variable.

```
libname abc spss 'FILENAME.POR';
proc contents data=abc._all_ out=new;
run;

filename sascode temp;
data _null_;  
set new;
file sascode
if formatd > formatl then do;
revision=cat(\text{format,formatl,}'\cdot.2'));
put 'format' +1 name +1 revision ' '; 
end;
run;

data temp;
set abc._all_;  
%inc sascode/source2;
run;
```

Note: The OPTIONS NOFMTERR statement does not allow SAS to use a data set with a DATA step or the table viewer. You have to reformat numeric variables that have a larger decimal value than their width before you can use a DATA step or the table viewer.

Example: SPSS Engine

The following example associates the libref Mylib with the physical file /users/myid/mydir/myspssx.por to execute the CONTENTS and PRINT procedures on the export file:

```
libname mylib spss '/users/myid/mydir/myspssx.por';
proc contents data=mylib._first_;  
proc print data=mylib._first_;  
run;
```

In the next example, the FILENAME statement associates the fileref mylib2 with the /users/myid/mydir/aspssx.por SPSS physical file, and the LIBNAME statement associates the libref with the SPSS engine. The PRINT procedure writes the data from the portable file.

```
filename mylib2 '/users/myid/mydir/aspssx.por';
```
libname mylib2 spss;
proc print data=mylib2._first_
run;

Support for Links in UNIX Environments

SAS provides limited support for hard links and symbolic links in UNIX environments. You can create links that point to a SAS data set or SAS catalog. If you reference the link in a SAS program, SAS follows the link to find the data set or catalog.

For example, you can create a symbolic link in the /tmp directory to the /home/user/mydata.sas7bdat data set by entering the following command at the UNIX prompt:

```
ln -s /home/user/mydata.sas7bdat /tmp/mydata.sas7bdat
```

The following SAS code uses the symbolic link in the /tmp directory to find the mydata.sas7bdat data set. This code does not change the symbolic link, but it does sort the data in the data set.

```
libname tmp '/tmp';

proc sort data=tmp.mydata;
  by myvariable;
run;
```

If you are running in the SAS windowing environment, you can use the SAS Explorer window to view the symbolic links that are stored within a specific directory. Any symbolic link that points to a nonexistent SAS file has a file size of 0.0KB and a modified date of 31DEC59:19:00:00.

Note: SAS does not support links for a version data set or for a data set that has an index.

Reading from and Writing to UNIX Commands (PIPE)
  What Are Pipes?
Introduction to External Files and Devices in UNIX Environments

At times during a SAS session, you might want to use external files. That is, you might want to use files that contain data or text, or files in which you want to store data or text. These files are created and maintained by other applications or by SAS. You can create, read, write, and delete external files from within SAS.

You can use external files in a SAS session to perform the following functions:

- Hold raw data to be read with the INPUT statements
- Store printed reports created by a SAS procedure
- Submit a file containing SAS statements for processing
- Store data written with PUT statements

For SAS, external files and devices can serve both as sources of input and as receivers of output. The input can be either raw data to be read in a DATA step or SAS statements to be processed by SAS. The output can be one of the following:

- The SAS log, which contains notes and messages produced by the program
- The formatted output of SAS procedures
- Data written with PUT statements in a DATA step

You might also want to use peripheral devices such as a printer, plotter, or your own terminal. UNIX treats these I/O devices as if they were files. Each device is associated with a file, called a special file, which is treated as an ordinary disk file. When you write to a special file, the associated device is automatically activated. All special files reside in the dev directory or its subdirectories. Although there are some differences in how you use the various devices, the basic concept is the same for them all.

UNIX also enables you to use pipes to send data to and from operating system commands as if they were I/O devices.
If you need to access an external file containing a transport data library, see *Moving and Accessing SAS Files*.

## Accessing an External File or Device in UNIX Environments

### Specifying a Pathname or a Fileref

To access an external file or device, you need to specify its pathname or fileref in the appropriate SAS statements:

- **FILE**
  - specifies the current output file for PUT statements.
- **%INCLUDE**
  - includes a file that contains SAS source statements that are executed when you submit a program from the Program Editor.

**TIP** If you use `%INCLUDE`, the line limit is 6000 bytes.

- **INFILE**
  - identifies an external file that you want to read with an INPUT statement.

In the SAS statement, refer to the file or device in one of two ways:

- Specify the pathnames for the external files. For more information, see “Specifying Pathnames in UNIX Environments” on page 82.
- Assign a fileref to a device, one or more files, or a directory, and use the fileref when you want to refer to the file, directory, or device.

In most cases, you should use a fileref.

### What Is a Fileref?

A fileref is nickname that you assign to a file or device. You assign the fileref once, and then use it as needed. Filerefs are especially useful under the following conditions:

- The pathname is long and has to be specified several times within a program.
- The pathname might change. If the pathname changes, you need to change only the statement that assigns the fileref, not every reference to the file.

You can assign filerefs in the File Shortcuts window of the Explorer, with the FILENAME statement, with the FILENAME function, or by defining the fileref as an environment variable.
Specifying Pathnames in UNIX Environments

Rules for Specifying Pathnames

You can reference an external file directly by specifying its pathname in the FILE, INFILE, or %INCLUDE statements. You can reference the file indirectly by specifying a fileref and a pathname in the FILENAME statement and then using the fileref in the FILE, INFILE, or %INCLUDE statements.

Whether you reference a file directly or indirectly, you need to specify its pathname in the appropriate statement. In most cases, you must enclose the name in quotation marks. For example, the following INFILE statement refers to the file /users/pat/cars:

```sas
infile '/users/pat/cars';
```

The following FILE statement directs output to a specified special device file:

```sas
file '/dev/tty1';
```

Note: If a filename has leading blanks, then the blanks are trimmed.

The level of specification depends on your current directory. You can use the character substitutions shown in Table 3.3 on page 62 to specify the pathname. You can also use wildcards as described in “Using Wildcards in Pathnames (Input Only)” on page 84.

Omitting Quotation Marks in a Filename

You can omit the quotation marks in a filename if one of the following is true:

- There is not already a fileref defined with that filename.
- The file has the file extension that is expected by the statement that you are using to refer to the file. If you do not enclose a filename in quotation marks, the FILE and INFILE statements assume a file extension of '.dat'. The %INCLUDE statement assumes a file extension of '.sas'.
- The file is located in the current directory.
- The filename is written with all lowercase characters.
For example, if the current directory is `/users/mkt/report` and it includes file `qtr.sas`, you can reference `qtr.sas` in any of the following statements:

```sas
%include '/users/mkt/report/qtr.sas';
%include 'qtr.sas';
file 'qtr.sas';
```

If there is no `qtr` fileref already defined, you can omit the quotation marks and the file extension in the `%INCLUDE` statement:

```sas
%include qtr;
```

---

### Working with Mixed Case or Uppercase Filenames

Filenames in the UNIX operating system are case sensitive. This means that a file named `PROGRAM` is not the same as a file named `program`. When you reference the name of a file that is written in mixed case or uppercase, and that filename is not enclosed in quotation marks, SAS converts the filename to lowercase. If the filename does not have a file extension, SAS adds the missing file extension.

For example, if you specify `%include code(PROGRAM);` in your program, SAS converts the filename `PROGRAM` to lowercase, and adds an extension of `.sas` to the filename. `PROGRAM` becomes `program.sas`.

---

### Interpreting the Messages in the SAS Log

When you execute the following program, SAS converts `TEMP` to `temp`, and adds an extension of `.sas` to the filename:

```sas
filename inc_code 'your-directory';
%include inc_code(TEMP);
```

SAS writes the following messages to the SAS log:

```
WARNING: Physical file does not exist, A.../your-directory/TEMP.sas.
ERROR: Cannot %INCLUDE member TEMP in the aggregate INC_CODE.
```

The warning message shows only the original filename (TEMP.sas), and not the lowercase conversion (temp.sas). This situation might cause confusion if a file named TEMP.sas does exist.

To avoid this confusion, include the file extension with the filename if the filename contains an extension. Enclose a mixed case or uppercase filename in quotation marks if the filename does not have an extension. For example:

```sas
%include code(TEMP.sas);
%include code("TEMP");
```

In both of these cases, SAS does not convert `TEMP` to lowercase.
Using Wildcards in Pathnames (Input Only)

Descriptions of the Valid Wildcards

You can use the *, ?, and [ ] wildcards to specify pathnames in the FILENAME (only if the fileref is to be used for input), INFILE, and %INCLUDE statements and the INCLUDE command.

*  matches one or more characters, except for the period at the beginning of filenames.

?  matches any single character.

[ ]  matches any single character from the set of characters defined within the brackets. You can specify a range of characters by specifying the starting character and ending character separated by a hyphen.

Wildcards are supported for input only. You cannot use wildcards in the FILE statement.

Example 1: Selecting Files By Including a Wildcard in a String

The following example reads input from every file in the current directory that begins with the string wild and ends with .dat:

```
filename wild 'wild*.dat';
data;
infile wild;
input;
run;
```

Example 2: Reading Each File in the Current Directory

The following example reads input from every file in every subdirectory of the current working directory:

```
filename subfiles '*/*';
data;
infile subfiles;
input;
run;
```

If new files are added to any of the subdirectories, they can be accessed with the Subfiles fileref without changing the FILENAME statement.
Example 3: Wildcards in Filenames When Using Aggregate Syntax

You can also use wildcards in filenames, but not in directory names, when you use aggregate syntax:

```plaintext
filename curdir ".";
data;
infile curdir('wild*');
input;
run;
```

In the example above, the period in the FILENAME statement refers to the current directory.

See “Valid Character Substitutions in Pathnames” on page 62 for information about character substitutions available in UNIX.

Example 4: Associating a Fileref with Multiple Files

The following statement associates the fileref MyRef with all files that begin with alphabetic characters. Files beginning with numbers or other characters such as the period or tilde are excluded.

```plaintext
filename myref '[a-zA-Z]*.dat';
```

The following statement associates MyRef with any file beginning with Sales (in either uppercase, lowercase, or mixed case) and a year between 2010 and 2019:

```plaintext
filename myref '[Ss][Aa][Ll][Ee][Ss][0-9][0-9]'.dat';
```

Assigning Filerefs to External Files or Devices with the FILENAME Statement

Introduction to the FILENAME Statement

The most common way to assign a fileref to an external file or device is with the FILENAME statement. There are several forms of the FILENAME statement, depending on the type of device that you want to access. For more information, see “FILENAME Statement: UNIX” on page 346.

Accessing DISK Files

The most common use of the FILENAME statement is to access DISK files. The FILENAME syntax for a DISK file is the following:

```plaintext
FILENAME fileref <DISK> 'pathname' <options>;
```
The following FILENAME statement associates the fileref `myfile` with the external file `/users/mydir/myfile`, which is stored on a disk device:

```plaintext
filename myfile disk '/users/mydir/myfile';
```

The following FILENAME statement assigns a fileref of `prices` to the file `/users/pat/cars`. The FILE statement then refers to the file using the fileref:

```plaintext
filename prices '/users/pat/cars';
data current.list;
file prices;
    ...PUT statements...
run;
```

For more information about using DISK files, see “Concatenating Filenames in UNIX Environments” on page 88.

---

**Note:** If a filename has leading blanks, then blanks are trimmed.

---

### Debugging Code with DUMMY Devices

You can substitute the DUMMY device type for any of the other device types. This device type serves as a tool for debugging your SAS code without actually reading or writing to the device. After debugging is complete, replace the DUMMY device name with the proper device type, and your program will access the specified device type.

Here is the FILENAME syntax for a DUMMY file:

```plaintext
FILENAME fileref DUMMY 'pathname' <options>;
```

Output to DUMMY devices is discarded.

---

### Sending Output to PRINTER Devices

The PRINTER device type enables you to send output directly to a printer. Here is the FILENAME syntax to direct a file to a PRINTER:

```plaintext
FILENAME fileref PRINTER '<printer> <printer-options>' <options>;
```

For example, this SAS program sends the output file to the BLDG3 printer:

```plaintext
filename myfile printer 'bldg3';
data test;
    file myfile;
    put 'This will appear in bldg3 .';
run;
```

For more information, see “Printing the Contents of a Window” on page 112 and “Using the PRINTTO Procedure in UNIX Environments” on page 114.
Using Temporary Files (TEMP Device Type)

The TEMP device type associates a fileref with a temporary file stored in the same directory as the Work library. (See “Work Library” on page 69.) Using the TEMP device type enables you to create a file that lasts only as long as the SAS session.

Here is the FILENAME syntax for a TEMP file:

FILENAME fileref TEMP <options>;

For example, this FILENAME statement associates Tmp1 with a temporary file:

filename tmp1 temp;

Accessing TERMINAL Devices Directly

To access a terminal directly, use the TERMINAL device type. Here is the FILENAME syntax to associate a file with a terminal:

FILENAME fileref TERMINAL <'terminal-pathname'> <options>;

The terminal-pathname must be a pathname of the special file associated with the terminal. Check with your UNIX system administrator for information. Enclose the name in quotation marks. If you omit the terminal pathname, the fileref is assigned to your terminal.

For example, this FILENAME statement associates the fileref here with your terminal:

filename here terminal;

The following FILENAME statement associates the fileref thatfile with another terminal:

filename thatfile terminal '/dev/tty3';

Assigning Filerefs to Files on Other Systems (FTP, SFTP, and SOCKET Access Types)

You can access files on other systems in your network by using the FTP, SFTP, and SOCKET access methods. Here are the forms of the FILENAME statement:

FILENAME fileref FTP 'external-file' <ftp-options>;
FILENAME fileref SFTP 'external-file' <sftp-options>;
FILENAME fileref SOCKET 'external-file' <tcpip-options>;
FILENAME fileref SOCKET ':portno' SERVER <tcpip-options>;

These access methods are documented in SAS DATA Step Statements: Reference. Under UNIX, the FTP access method supports an additional option:

MACH='machine'

identifies which entry in the .netrc file should be used to get the user name and password. The .netrc file resides on the host on which the SAS program is
running. See the UNIX man page for more information about the .netrc file. You cannot specify the MACH option together with the HOST option in the FILENAME statement.

If you are transferring a file to UNIX from the z/OS operating environment and you want to use either the S370V or S370VB format to access that file, then the file must be of type RECFM=U and BLKSIZE=32760 before you transfer it.

**CAUTION**

When you use the FTP access method to create a remote file, the UNIX permissions for that file are set to -rw-rw-rw-, which makes the file world-readable and world-writable. See the UNIX man page for chmod for information about changing file permissions.

---

### Concatenating Filenames in UNIX Environments

You can concatenate filenames in the FILENAME, %INCLUDE, and INFILE statements. Concatenating filenames enables you to read those files sequentially.

FILENAME `fileref ("pathname-1" ... "pathname-n")`;
%INCLUDE `{("filename-1" ... "filename-n")};`
%INCLUDE `"("filename-1" ... 'filename-n")";
INFILE `{("filename-1" ... "filename-n")};`
INFILE `"("filename-1" ... 'filename-n")";

You can enclose the pathnames in single or double quotation marks and separate them with commas or blank spaces. You can use the characters shown in Table 3.3 on page 62 and the wildcards described in "Using Wildcards in Pathnames (Input Only)" on page 84 to specify the pathnames.

### Assigning a Fileref to a Directory (Using Aggregate Syntax)

---

**Introduction to Aggregate Syntax**

**Aggregate Syntax**

Aggregate syntax enables you to assign a fileref to a directory and then work with any file in that directory by specifying its filename in parentheses after the fileref.
FILENAME fileref directory-name;

Aggregate syntax is especially useful when you have to refer to several files in one directory.

Example 1: Referring to a File Using Aggregate Syntax

To refer to a file in the directory, specify the fileref followed by the individual filename in parentheses. For example, you can refer to the file cars.dat in the directory /users/pat as shown in this example:

```sas
filename prices '/users/pat';
data current.list;
  file prices(cars);
  ...other SAS statements...
run;
```

Example 2: Using Aggregate Syntax with Filerefs Defined by Environment Variables

You can also use aggregate syntax with filerefs that have been defined using environment variables. (See “Using Environment Variables to Assign Filerefs in UNIX Environments” on page 90.) For example:

```sas
x setenv PRICES /users/pat;
data current.list;
  file prices(cars);
  ...other SAS statements...
run;
```

Assigning a Fileref to Several Directories

In the FILENAME statement, you can concatenate directory names and use the fileref to refer to any file within those directories:

FILENAME fileref ("directory-1" ... "directory-n");

When you concatenate directory names, you can use aggregate syntax to refer to a file in one of the directories. For example, assume that the Report.sas file resides in the directory associated with the MYPROGS environment variable. When SAS executes the following code, it searches for Report.sas in the pathnames that are specified in the FILENAME statement and it executes the program.

```sas
filename progs ("$MYPROGS" "/users/mkt/progs");
%inc progs(report);
```

SAS searches the pathnames in the order specified in the FILENAME statement until one of these situations occurs:

- it finds the first file with the specified name. Even if you use wildcards (see “Using Wildcards in Pathnames (Input Only)” on page 84) in the filename, SAS matches only one file.
- it encounters a filename in the list of pathnames that you specified in the FILENAME statement.
Using Environment Variables to Assign Filerefs in UNIX Environments

Requirements for Variable Names

An environment variable can also be used as a fileref to refer to DISK files. The variable name must be in all uppercase characters, and the variable value must be the full pathname of the external file. That is, the filename must begin with a slash.

Note: If a variable and a fileref have the same name but refer to different files, SAS uses the fileref. For example, the %INCLUDE statement below refers to file /users/myid/this_one.

```plaintext
filename ABC '/users/myid/this_one';
x setenv ABC /users/myid/that_one;
%include ABC;
```

Reading a Data File

If you want to read the data file /users/myid/educ.dat, but you want to refer to it with the INED environment variable, you can define the variable at two times:

- Before you invoke SAS, see “Defining Environment Variables in UNIX Environments” on page 285. For example, in the Korn shell, you use the following:
  ```plaintext
  export INED=/users/myid/educ.dat
  ```
- After you invoke SAS by using the X statement (see “Executing Operating System Commands from Your SAS Session” on page 17) and the SAS setenv command:
  ```plaintext
  x setenv INED /users/myid/educ.dat;
  ```

After INED is associated with the file /users/myid/educ.dat, you can use ined as a fileref to refer to the file in the INFILE statement:

```plaintext
infile ined;
```

Writing to an External File

The same method applies if you want to write to an external file. For example, you can define OUTFILE before you invoke SAS:
Then, use the environment variable name as a fileref to refer to the file:

file OUTFILE;

---

Filerefs Assigned by SAS in UNIX Environments

Filerefs for Standard Input, Standard Output, and Standard Error

Often a command's arguments or options tell the command what to use for input and output. If they do not, the shell supplies you with three standard files: one for input (standard input), one for output (standard output), and one for error messages (standard error). By default, these files are all associated with your terminal: standard input with your keyboard, and both standard output and standard error with your terminal's display. When you invoke SAS, it assigns a fileref to each file that it opens, including the three standard files. SAS assigns the filerefs Stdin, Stdout, and Stderr to standard input, standard output, and standard error, respectively.

File Descriptors

What Is a File Descriptor?

Each file has an assigned internal file descriptor. By default, 0 is the file descriptor for standard input, 1 is the file descriptor for standard output, and 2 is the file descriptor for standard error. As other files are opened, they get other file descriptors. In the Bourne shell and in the Korn shell, you can specify that data be written to or be read from a file using the file descriptor (see below).

File Descriptors in the Bourne and Korn Shells

If you are using the Bourne shell or the Korn shell, SAS assigns filerefs of the following form to files that have a file descriptor larger than 2.

FILDES

number

number is a two-digit representation of the file descriptor. You can use these filerefs in your SAS applications.

For example, if you invoke SAS with the following command, then the operating environment opens the file sales_data and assigns file descriptor 4 to it:

sas salespgm 4< sales_data

SAS assigns the fileref FILDES04 to the file and executes the application salespgm. When the application reads input from FILDES04, it reads the file sales_data. Using
file descriptors as filerefs enables you to use the same application to process data from different files without changing the application to refer to each file. In the command that you use to invoke the application, you assign the appropriate file descriptor to the file to be processed.

Reserved Filerefs in UNIX Environments

The following filerefs are reserved.

DATALINES fileref in the INFILE statement
  specifies that input data immediately follow a DATALINES statement. You need to use INFILE DATALINES only when you want to specify options in the INFILE statement to read instream data.

LOG fileref in the FILE statement
  specifies that output lines produced by PUT statements be written to the SAS log. LOG is the default destination for output lines.

PRINT fileref in the FILE statement
  specifies that output lines produced by PUT statements be written to the same print file as output produced by SAS procedures.

Sharing External Files in a UNIX Environment

Sharing External Files

If more than one user has simultaneous Write access to an external file, or if a single user has Write access to the same file from different SAS sessions, the results of sharing the file can be unpredictable. To remedy this situation, you can use a statement option or a system option to restrict Write access to one user, while allowing multiple users Read access. For more information, see “Sharing SAS Files” on page 50.

Options to Use for File Locking: External Files

File locking applies to all files that are opened. You can turn off file locking for external files in the following ways:

- Use the LOCKINTERNAL option in the FILENAME statement.
- Use the FILELOCKS system option.
File Locking for External Files: The LOCKINTERNAL Statement Option

You can control file locking for external files by using the LOCKINTERNAL option in the FILENAME statement. The AUTO option value locks a file exclusively for Write access, or non-exclusively for Read access. For example, if a file is opened for update or output, then all other access from internal processes are blocked. If a file is opened for input, then other users can also open the file for input. In this case, opening the file for update and output is blocked. The SHARED option value allows for all of the behavior of the AUTO option, except that the file can be shared by one writer and multiple readers. The external file that is associated with the fileref is the file that is locked. By default, multiple users can simultaneously read an external file. For more information, see “FILENAME Statement: UNIX” on page 346.

File Locking for External Files: The FILELOCKS System Option

You can control file locking for external files (as well as for SAS files) by using the FILELOCKS system option. This option enables you to apply a behavior globally to individual files or directories. Using FILELOCKS restricts writer access to one user. With file locking turned on, multiple SAS sessions are able to simultaneously read the same file. You can use FILELOCKS at start-up, in the OPTIONS statement, or in the command line. You can specify multiple instances of the FILELOCKS option. Each instance is added to an internal table of paths and settings. For more information, see “FILELOCKS System Option: UNIX” on page 397.

Reading from and Writing to UNIX Commands (PIPE)

What Are Pipes?

Pipes enable your SAS application to receive input from any UNIX command that writes to standard output and to route output to any UNIX command that reads from standard input. In UNIX commands, the pipe is represented by a vertical bar (|). For example, to find the number of files in your directory, you could redirect the output of the ls command through a pipe to the wc (word count) command:

```
ls | wc -w
```
Syntax of the FILENAME Statement to Assign a Fileref to a Pipe

Under UNIX, you can use the FILENAME statement to assign filerefs not only to external files and I/O devices, but also to a pipe. Here is the syntax of the FILENAME statement:

FILENAME fileref PIPE 'UNIX-command' <options>;

fileref
is the name by which you reference the pipe from SAS.

PIPE
identifies the device-type as a UNIX pipe.

'UNIX-command'
is the name of a UNIX command, executable program, or shell script to which you want to route output or from which you want to read input. The commands must be enclosed in either double or single quotation marks.

options
control how the external file is processed. For an explanation of these options, see “FILENAME Statement: UNIX” on page 346.

Whether you are using the command as input or output depends on whether you use the fileref in a reading or writing operation. For example, if the fileref is used in an INFILE statement, then SAS assumes that the input comes from a UNIX command. If the fileref is used in a FILE statement, then SAS assumes that the output goes to a UNIX command.

Using the Fileref for Reading

Specifying a Fileref for Reading

When the fileref is used for reading, the specified UNIX command executes, and any output sent to its standard output or standard error is read through the fileref. In this case, the standard input of the command is connected to /dev/null.

Example 1: Sending the Output of the Process Command to a SAS DATA Step

The following SAS program uses the PIPE device-type keyword to send the output of the ps (process) command to a SAS DATA step. The resulting SAS data set contains data about every process currently running SAS:

    filename ps_list pipe "ps -e|grep 'sas'";
    data sasjobs;
        infile ps_list;
        length process $ 80;
        input process $ char80.;
    run;
The `ps -e` command produces a listing of all active processes in the system, including the name of the command that started the task. In BSD-based UNIX systems, you use the `ps -ax` command.

The operating environment uses pipes to send the output from `ps` to the `grep` command, which searches for every occurrence of the string 'sas'. The `FILENAME` statement connects the output of the `grep` command to the fileref `ps_list`. The DATA step then creates a data set named `sasjobs` from the INFILE statement that points to the input source. The INPUT statement reads the first 80 characters on each input line.

### Example 2: Using the Stdin Fileref to Read Input

In the next example, the Stdin fileref is used to read input through a pipe into the SAS command, which, in turn, executes the SAS program. By placing the piping operation outside the SAS program, the program becomes more general. The program in the previous example has been changed and stored in file `ps.sas`:

```sas
data sasjobs;
  infile stdin;
  length process $ 80;
  input process $ char80.;
run;
proc print data=sasjobs;
run;
```

To run the program, use pipes to send the output of `ps` to `grep` and from `grep` into the SAS command:

```
ps -e|grep 'sas'|sas ps.sas &
```

The output is stored in `ps.lst`, and the log is stored in `ps.log`, as described in "The Default Routings for the SAS Log and Procedure Output in UNIX Environments" on page 105.

---

**Using the Fileref for Writing**

### Specifying a Fileref for Writing

When the fileref is used for writing, the output from SAS is read in by the specified UNIX command, which then executes.

### Example 1: Sending Mail Using Pipes

In this example, any data sent to the `mail` fileref are piped to the `mail` command and sent to user PAT:

```
filename mail pipe 'mail pat';
```

### Example 2: Starting a Remote Shell and Printing Output

Consider this `FILENAME` statement:
Any data sent to the `letterq` fileref is passed to the UNIX command, which starts a remote shell on the computer named Alpha. Note that the form of the command that starts a remote shell varies among the various UNIX operating systems. The shell then prints the `letterq` output on the printer identified by the destination BLDGA3. Any messages that are produced by the `lp` command are sent to the SAS log.

**Sending Electronic Mail Using the FILENAME Statement (EMAIL)**

### Advantages of Sending Electronic Mail from within SAS

SAS lets you send electronic mail using SAS functions in a DATA step or in SCL. Sending email from within SAS enables you to do the following:

- Use the logic of the DATA step or SCL to subset email distribution based on a large data set of email addresses.
- Send email automatically upon completion of a SAS program that you submitted for batch processing.
- Direct output through email based on the results of processing.
- Send email messages from within a SAS/AF frame application, customizing the user interface.

### Initializing Electronic Mail

By default, SAS uses SMTP (Simple Mail Transfer Protocol) to send email. SMTP, unlike some external scripts, supports attachments. This default is specified by the EMAILSYS system option. For information about how to change the email protocol, see “EMAILSYS System Option: UNIX” on page 395.

Before you can send email from within SAS, your system administrator might need to set the EMAILHOST system option to point to the SMTP server. For more information, see “EMAILHOST= System Option” in SAS System Options: Reference.

### Components of the DATA Step or SCL Code Used to Send Email

In general, a DATA step or SCL code that sends electronic mail has the following components:

- a FILENAME statement with the EMAIL device-type keyword
options specified in the FILENAME or FILE statements indicating the email recipients, subject, and any attached files

- PUT statements that contain the body of the message

- PUT statements that contain special email directives (of the form `!EM_directive!`) that can override the email attributes (TO, CC, BCC, SUBJECT, ATTACH) or perform actions (such as SEND, ABORT, and start a NEWMSG)

---

Syntax of the FILENAME Statement for Electronic Mail

To send electronic mail from a DATA step or SCL, issue a FILENAME statement of the following form:

```
FILENAME fileref EMAIL 'address' <email-options>
```

The FILENAME statement accepts the following options:

- **fileref** is a valid fileref.
- **address** is the destination email address of the user to which you want to send email. You must specify an address here, but you can override its value with the TO email option.
- **email-options** can be any of the following:
  - **TO=to-address** specifies the primary recipients of the electronic mail. If an address contains more than one word, enclose it in quotation marks. To specify more than one address, enclose the group of addresses in parentheses, enclose each address in quotation marks, and separate each address with a space. For example, `to='joe@someplace.org'` and `to=('joe@smplc.org" jane@diffplc.org")` are valid TO values.
  - **CC=cc-address** specifies the recipients that you want to receive a copy of the electronic mail. If an address contains more than one word, enclose it in quotation marks. To specify more than one address, enclose the group of addresses in parentheses, enclose each address in quotation marks, and separate each address with a space. For example, `cc='joe@someplace.org'` and `cc=('joe@smplc.org" jane@diffplc.org")` are valid CC values.
  - **BCC=bcc-address** specifies the recipients that you want to receive a blind copy of the electronic mail. Individuals listed in the BCC field receive a copy of the email. The BCC field does not appear in the email header, so that these email addresses cannot be viewed by other recipients.

Note: You can send an email without specifying a recipient in the TO= option as long as you specify a recipient in either the CC= or BCC= option.

---

CC and BCC address rules:

- If a BCC address contains more than one word, enclose it in quotation marks. To specify more than one address, enclose the group of addresses in parentheses, enclose each address in quotation marks, and separate each address with a space.
space. For example, `bcc='joe@someplace.org'` and `bcc=("joe@mplc.org" "jane@diffplc.org")` are valid BCC values.

**SUBJECT='subject'**
specifies the subject of the message. If the subject text is longer than one word (that is, it contains at least one blank space), you must enclose it in quotation marks. You also must use quotation marks if the subject contains any special characters. For example, `subject=Sales` and `subject='June Report'` are valid subjects. Any subject not enclosed in quotation marks is converted to uppercase.

**ATTACH='filename.ext' | ATTACH= ('filename.ext' <attachment-options>)**
specifies the physical names of the files to be attached to the message and any options to modify attachment specifications. Enclose `filename.ext` in quotation marks. To attach more than one file, enclose the group of filenames in parentheses. For example, `attach="/u/userid/opinion.txt"` and `attach=("june11.txt" "july11.txt")` are valid file attachments.

By default, an SMTP email attachment has the same value as the default value of LRECL, which is 32K. To send a longer attachment, you can specify the LRECL= and RECFM= options from the FILENAME statement as attachment-options. For more information about the LRECL= and RECFM= options, see "FILENAME Statement: UNIX" on page 346.

For more information about the options that are valid when you are using SMTP, see "FILENAME Statement: EMAIL (SMTP) Access Method" in SAS Global Statements: Reference.

---

**Specifying Email Options in the FILE Statement**

You can also specify the `email-options` in the FILE statement inside the DATA step. Options that you specify in the FILE statement override any corresponding options that you specified in the FILENAME statement.

---

**Defining the Body of the Message**

In your DATA step, after using the FILE statement to define your email fileref as the output destination, use PUT statements to define the body of the message.

---

**Specifying Email Directives in the PUT Statement**

You can also use PUT statements to specify email directives that change the attributes of your electronic message or perform actions with it. Specify only one directive in each PUT statement; each PUT statement can contain only the text associated with the directive that it specifies.

Here are the directives that change the attributes of your message:

**!EM_TO! addresses**

Replace the current primary recipient addresses with `addresses`. In the PUT statement, specify `addresses` without single quotation marks.
addresses
Replace the current copied recipient addresses with addresses. In the PUT statement, specify addresses without single quotation marks.

addresses
Replace the current blind copied recipient addresses with addresses. In the PUT statement, specify addresses without single quotation marks.

subject
Replace the current subject of the message with subject.

pathname
Replace the names of any attached files with pathname.

Here are the directives that perform actions:

SEND!
Sends the message with the current attributes. By default, SAS sends a message when the fileref is closed. The fileref closes when the next FILE statement is encountered or the DATA step ends. If you use this directive, SAS sends the message when it encounters the directive, and again at the end of the DATA step.

ABORT!
Aborts the current message. You can use this directive to stop SAS from automatically sending the message at the end of the DATA step.

NEWMSG!
Clears all attributes of the current message, including TO, CC, SUBJECT, ATTACH, and the message body.

Example: Sending Email from the DATA Step

Suppose that you want to share a copy of your config.sas file with your coworker Jim, whose user ID is JBrown. If your email program handles alias names and attachments, you could send it by submitting the following DATA step:

```sas
filename mymail email 'JBrown'
subject='My CONFIG.SAS file'
attach='config.sas';

data _null_; file mymail;
put 'Jim,';
put 'This is my CONFIG.SAS file.';
put 'I think you might like the
    new options I added.';
run;
```

The following example sends a message and two attached files to multiple recipients. It specifies the email options in the FILE statement instead of the FILENAME statement:

```sas
filename outbox email 'ron@acme.com';

data _null_; file outbox
```
You can use conditional logic in the DATA step to send multiple messages and control which recipients get which message. For example, suppose you want to send customized reports to members of two different departments. If your email program handles alias names and attachments, your DATA step might look like the following:

```
filename reports email 'Jim';

data _null_;
  file reports;
  infile cards eof=lastobs;
  length name dept $ 21;
  input name dept;

    /* Assign the TO attribute */
    put '!EM_TO!' name;

    /* Assign the SUBJECT attribute */
    put '!EM_SUBJECT! Report for ' dept;

    put name ',
    put 'Here is the latest report for ' dept '.

    /* ATTACH the appropriate report */
    if dept='marketing' then
      put '!EM_ATTACH! mktrept.txt';
    else
      put '!EM_ATTACH! devrept.txt';

    /* Send the message */
    put '!EM_SEND!';

    /* Clear the message attributes */
    put '!EM_NEWMSG!';

return;

/* Abort the message before the */
/*   RUN statement causes it to */
/*   be sent again.            */
lastobs: put '!EM_ABORT!';

datalines;
```
The resulting email message and its attachments are dependent on the department to which the recipient belongs.

Note: You must use the !EM_NEWMSG! directive to clear the message attributes between recipients. The !EM_ABORT! directive prevents the message from being automatically sent at the end of the DATA step.

Example: Sending Email Using SCL Code

The following example is the SCL code behind a frame entry design for email. The frame entry includes several text entry fields that let the user enter information:

- **mailto**: the user ID to send mail to
- **copyto**: the user ID to copy (CC) the mail to
- **attach**: the name of a file to attach
- **subject**: the subject of the mail
- **line1**: the text of the message

The frame entry also contains a button named SEND that causes this SCL code (marked by the send: label) to execute.

```scl
send:
  rc = filename('mailit','userid','email');
  if rc = 0 then do;
    fid = fopen('mailit','o');
    if fid > 0 then do;
      fputrc1  = fput(fid,line1);
      rc = fwrite(fid);
      fputrc2  = fput(fid,'!EM_TO! '||mailto);
```
Running External Lua Files

You can run external scripts written in the Lua programming language from the SAS command line. You can run both uncompiled Lua scripts (*.lua files) or precompiled Lua scripts (*.luc files). Support for running external Lua files was added in SAS 9.4M3.

To run the files, use the -SYSIN option on the SAS command line. For example, to run the file abc.lua, submit this command:

sas -sysin abc.lua

You can also run external Lua scripts (*.lua or *.luc files) using the %INCLUDE statement in a SAS session. For example, to run the Lua script abc.luc, enter the following line in your SAS program:

%include "./tmp/abc.luc";

Overview of Printing Output in UNIX Environments

When you print text or graphics, SAS needs to know where the output should go, how it should be written, and how the output should look. Universal Printing is the default printing mechanism in UNIX. Universal Printing supports PostScript, PCL, GIF, PNG, SVG, EMF, and PDF files in all environments. For more information about Universal Printing, see "Universal Printing" in SAS Language Reference: Concepts.

Forms printing is an older method of text printing available from SAS. It involves using the FORM subsystem, which consists of the Form window. For information, see "Forms Printing" in SAS Language Reference: Concepts.

If you are printing graphics, the output is controlled by native SAS/GRAPH drivers. See the online Help for SAS/GRAPH for information about native SAS/GRAPH drivers.

Previewing Output in UNIX Environments

Previewing Output Using Universal Printing

With Universal Printing, you can preview your output before you send it to a printer, plotter, or external file. To preview your output, you first need to define a previewer for your system. For more information, see "Universal Printing" in SAS Language Reference: Concepts.

Previewing Output from within SAS/AF Applications

To preview output from within a SAS/AF application, use the DMPRTMODE and DMPRTPREVIEW commands to turn on preview mode, print the output, open the Print Preview dialog box, and then turn preview mode off. For example, the following code prints the GRAPH1 object using the host drivers and displays it in the Preview dialog box:

/* Turn on preview mode. */
CALL EXECCMDI ("DMPRTMODE PREVIEW");

/* Print the graph */
GRAPH1._PRINT_();

/* Open the Preview dialog box */
CALL EXECCMDI ("DMPRTPREVIEW");
The Default Routings for the SAS Log and Procedure Output in UNIX Environments

For each SAS job or session, SAS automatically creates two types of output:

SAS log

- contains information about the processing of SAS statements. As each program step executes, notes are written to the SAS log along with any applicable error or warning messages.

SAS output

- is also called the procedure output file or print file. Whenever a SAS program executes a PROC step or a DATA step that produces printed output, SAS sends the output to the SAS output file. The default destination for SAS output is HTML.

The following table shows the default routings of the SAS log and output files.

Table 5.1 Default Routings of the SAS Log and Output Files

<table>
<thead>
<tr>
<th>Processing Mode</th>
<th>SAS Log File</th>
<th>SAS Output File</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch</td>
<td><code>filename.log</code></td>
<td><code>filename.lst</code></td>
</tr>
<tr>
<td>windowing environment</td>
<td>Log window</td>
<td>HTML</td>
</tr>
<tr>
<td>interactive line</td>
<td>terminal</td>
<td>terminal</td>
</tr>
</tbody>
</table>

By default, both the log file and the output file are written to your current directory. Your system administrator might have changed these default routings.

Changing the Default Routings in UNIX Environments

Techniques for Routing Output

Here are the primary methods for routing your output:

- Using the default HTML destination.
Using the Print dialog box. The Print dialog box is available when you are using the SAS windowing environment.

Issuing windowing environment commands. The PRTFILE, PRINT, and FILE commands can be issued from any command line. You can use these commands to send output to external files or to other devices defined with the FILENAME statement.

Using the PRINTTO procedure. You can use the PRINTTO procedure in any mode. Using the FILENAME statement with the PRINTTO procedure is the most flexible way of routing your output.

Using SAS system options, such as PRINT, LOG, ALTPRINT, or ALTLOG, to specify alternate destinations.

Determining Which Technique to Use When Changing the Routing

Use the following table to help you decide which method you should choose to change the routing.

**Table 5.2 Decision Table: Changing the Default Destination**

<table>
<thead>
<tr>
<th>Output destination for your SAS log or procedure output</th>
<th>Processing mode</th>
<th>Method</th>

Routing SAS Logging Facility Messages to SYSLOGD

The SAS logging facility enables the categorization and collection of log event messages, and then writes them to a variety of output devices. The logging facility
supports problem diagnosis and resolution, performance and capacity management, and auditing and regulatory compliance. The following features are provided:

- Log events are categorized using a hierarchical naming system that enables you to configure logging at a broad or a fine-grained level.
- Log events can be directed to multiple output destinations, including files, operating system facilities, databases, and client applications. For each output destination, you can specify these items:
  - the categories and levels of log events to report
  - the message layout, including the types of data to be included, the order of the data, and the format of the data
  - filters based on criteria such as diagnostic levels and message content
- Logging diagnostic levels can be adjusted dynamically without starting and stopping processes.
- Performance-related log events can be generated for processing by an Application Response Measurement (ARM) 4.0 server.

The logging facility is used by most SAS server processes. You can also use the logging facility within SAS programs.

In the UNIX operating environment, logging facility messages can be written to SYSLOGD.

For information about using the logging facility in the UNIX operating environment, see the SAS Logging: Configuration and Programming Reference.

Using the Print Dialog Box in UNIX Environments

Printing from Text Windows

Open the Print Dialog Box from a Text Window

To print part or all of the contents of a window:

1. Click in the window to make it the active window. If you want to mark and print only selected lines of text, mark the text before you open the Print dialog box.

2. Issue the DMPRINT command or select File ➔ Print to open the Print dialog box.
Default Printing Mode

In UNIX, the default printing mode is Universal Printing. For more information about how to use Universal Printing, click Help on the Print dialog box.

Specifics for Forms Printing

To use forms for printing, select Use forms. SAS prompts you to enter a spool command and the name of your system printer. When you click OK, SAS prints the contents of the active window using the command and printer name that you specified and additional information from your default form. For more information about forms printing, see “Forms Printing” in SAS Language Reference: Concepts.

Troubleshooting Print Server Errors

After clicking OK, if SAS displays a clock icon for a long time and you are sending output to a network printer, your printer server might be down. If so, you eventually see a message in the shell where you invoked your SAS session that indicates that the server is down.
Printing from GRAPh Windows

Open the Print Dialog Box from the GRAPh Window

With Universal Printing, you can use the Print dialog box to print the contents of a SAS/GRAPh window. Click in the window to make it the active window, and then issue the DMPRINT command or select **File ➔ Print** to open the Print dialog box.

*Figure 5.2 Print Dialog Box for Graphs*

![Print Dialog Box for Graphs](image)

**Note:** In most cases, fonts set through the Print dialog box have no effect when you print from GRAPh windows. However, some SAS/GRAPh drivers use Universal Printing and can be affected by the fonts set in the dialog box. Make sure that you specify the correct options in a GOPTIONS statement.

**Specifics for SAS/GRAPh Drivers**

To print output using a SAS/GRAPh driver, select **Use SAS/GRAPh Drivers**. Select the down arrow beside the **Driver** field to display the available drivers. Make sure that your printer destination has been set inside the device using the GDEVICE procedure or the GOPTIONS statement. For complete information about printing from GRAPh windows, see **SAS/GRAPh: Reference** and the online Help for SAS/GRAPh.

**Troubleshooting Print Server Errors**

After clicking **OK**, if SAS displays a clock icon for a long time and you are sending output to a network printer, your printer server might be down. If so, you eventually see a message in the shell where you invoked your SAS session that indicates that the server is down.
Differences between the PRTFILE, PRINT, and FILE Commands

In the SAS windowing environment, you can use the PRTFILE, PRINT, and FILE commands to send the contents of the active window to an output device.

The following table lists the results of each of these commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>Action Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRTFILE</td>
<td>specifies the filename or fileref for your output.</td>
</tr>
<tr>
<td>FILE</td>
<td>sends the contents of the active window to the filename or fileref that you specify.</td>
</tr>
<tr>
<td>PRINT</td>
<td>sends the contents of the active window either:</td>
</tr>
<tr>
<td></td>
<td>- to your default printer when issued from the command line of the window.</td>
</tr>
<tr>
<td></td>
<td>- to the location specified with the PRTFILE command.</td>
</tr>
</tbody>
</table>

Sending Output to a UNIX Command

If you want to send your output to a UNIX command, you can use the FILENAME statement. The FILENAME statement enables you to create filerefs that point to printers, plotters, or external files or filerefs that pipe to a UNIX command. For more information, see “FILENAME Statement: UNIX” on page 346.

Specifying the Print File

When you issue the PRINT command, SAS sends your output to your default printer, unless you specify a print file. You can specify a print file by entering the PRTFILE command (for example, PRTFILE file-spec CLEAR | APPEND | REPLACE). The file-spec argument can be either a fileref or a filename.
If you are using forms printing, and you select **File ➔ Print**, a window appears that enables you to select file options. When you select **Print to File**, the Save As window appears. Enter the location to which you want your file saved. This option is available only when Universal Printing is turned off.

---

**Printing the Contents of a Window**

**Using PRTFILE and PRINT with a Fileref**

You can use the PRTFILE command, followed by the PRINT command, to print the contents of windows. PRTFILE establishes the destination, and PRINT sends the contents of the window to that destination. If you do not specify a destination with the PRTFILE command, PRINT automatically sends the window contents to your default printer.

**Steps for Sending Output Directly to a Printer**

If you want to send output directly to a printer, you must first submit the FILENAME statement to assign a fileref to the PRINTER or PIPE device. For example, to print the contents of your Output window, complete the steps in the following table.

*Table 5.4  Printing the Contents of Your Output Window*

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Example</th>
</tr>
</thead>
</table>
| 1    | Submit a FILENAME statement or FILENAME function to associate a fileref with a system printer (PRINTER device type) or a UNIX command (PIPE device type). Enclose the printer name or UNIX command in either single or double quotation marks. | filename myrpt printer 'bldga2';  
|      |        | or     |
|      |        | filename ascout pipe 'lp -dmyljet';  
|      |        | For more information, see "Examples of FILENAME Statements Using PRINTER and PIPE " on page 113. |
| 2    | Issue the PRTFILE command as described in "Specifying the Print File" on page 111. Specify the fileref from your FILENAME statement or FILENAME function. | prtfile myrpt |
| 3    | Issue the PRINT command from the command line of the windows whose contents you want to print. If you are sending output to a system printer or if you are using forms-based printing, then you can print the contents of more than one window. | |
Step | Action | Example
--- | --- | ---
4 | Enter \ in the dialog box that warns you that the destination file already exists. The \ value tells SAS to append the window contents to the destination file. | 
5 | Submit a FILENAME statement or FILENAME function to clear (deassign) the fileref. | filename myrpt clear;

To clear the print file setting, issue the PRTFILE CLEAR command.

**Examples of FILENAME Statements Using PRINTER and PIPE**

The following statement associates MyRpt with the system printer named BldgA2 and specifies two copies of every printout:

```
filename myrpt printer 'bldga2 -n2';
```

(See the documentation for your print command for information about other options that you can specify.)

The following statement enables you to print output using the `lp` command on the printer named Myljet:

```
filename ascout pipe 'lp -dmyljet';
```

The following statement sends output to the `lp` command and redirects any error messages produced by this command to the LpError file in your home directory:

```
filename myrpt pipe 'lp 2>$HOME/lperror';
```

**Note:** Redirecting standard error is allowed only in the Bourne and Korn shells.

If you frequently use the same print command and destination, you can add the appropriate FILENAME statement to your autoexec file. For more information, see “Customizing Your SAS Session By Using System Options” on page 21.

**Using the FILE Command**

You can use the FILE command to copy the contents of many different windows to external files. Issue the FILE command on the command line of the window whose contents you want to copy. For example, to copy the contents of the Log window to `/u/myid/log/app1`, issue the following command on the command line of the Log window:

```
file '/u/myid/log/app1'
```

If the file does not exist, SAS creates it. If the file already exists, a dialog box asks you whether you want to replace it or to append data to the existing data.
If you have already associated a fileref with your external file, you can use the fileref instead of the filename:

```
file myref
```

If you use the FILE command to save your output, carriage-control information is not saved (that is, page breaks are removed from the output). You might want to use the PRINT command with the FILE option instead:

```
PRINT FILE=fileref | 'pathname'
```

---

**Using the PRINTTO Procedure in UNIX Environments**

**Important Note about the PRINTTO Procedure**

Anytime you use PROC PRINTTO to route output, you must close the output device before PROC PRINTTO will release the output or log and send it to the destination that you have specified. To close the output device, issue PROC PRINTTO without any parameters:

```
proc printto;
run;
```

Issuing PROC PRINTTO without any parameters closes the output device, generates output, and reroutes the log and procedure output to their default destinations. For a list of the default destinations, see Table 5.1 on page 105.

For more information, see Chapter 30, “PRINTTO Procedure,” on page 503 and “PRINTTO Procedure” in Base SAS Procedures Guide.

---

**Using the LOG= and PRINT= Options**

When you use the PRINTTO procedure with its LOG= and PRINT= options, you can route the SAS log or SAS procedure output to an external file or a fileref from any mode. Specify the external file or the fileref in the PROC PRINTTO statement. The following example routes procedure output to `/u/myid/output/prog1`:

```
proc printto print='/u/myid/output/prog1' new;
run;
```

The NEW option causes any existing information in the file to be cleared. If you omit the NEW option from the PROC PRINTTO statement, the SAS log or procedure output is appended to the existing file.

If you plan to specify the same destination several times in your SAS program, you can assign a fileref to the file using a FILENAME statement. (For information and examples, see “Assigning Filerefs to External Files or Devices with the FILENAME Statement” on page 85.)
Routing Output to a Universal Printer

You can direct output directly to your Universal Printer by using the UPRINTER device type:

``` SAS
filename myoutput uprinter;
proc printto print=myoutput;
run;
```

Output is sent to your default Universal Printer. This output is in PostScript or PCL format.

Routing Output to a Printer

You can direct output directly to your system printer by using the PRINTER device type:

``` SAS
filename myoutput printer;
proc printto print=myoutput;
run;
```

Output is sent to your default system printer or, if you have specified the SYSPRINT system option, to the printer specified with that option. This method produces output in ASCII format.

Piping Output to a UNIX Command

You can also use the PIPE device type to send output to a UNIX command. When you specify the print command, you might also want to specify a destination for any error messages that are produced by the print command. Enclose the UNIX command in either single or double quotation marks. The following example associates the fileref MyOutput with the print command `lp`, which sends output to the printer named Myljet:

``` SAS
filename myoutput pipe 'lp -dmyljet';
proc printto print=myoutput;
run;
```

You can send the SAS log to the same printer by using the LOG= option:

``` SAS
filename mylog pipe 'lp -dmyljet';
proc printto log=mylog;
run;
```

The log and procedure output continue to be routed to the designated external file until another PROC PRINTTO statement reroutes them.
Routing Output to a Terminal

In batch mode, you can direct output to a terminal by associating a fileref with a terminal and then using PROC PRINTTO to send output to that fileref. In the FILENAME statement, specify the TERMINAL device-type and the special file associated with the terminal. For example, the following statements send the SAS log to the terminal that is associated with the /dev/tty3 special file:

```sas
filename term terminal '/dev/tty3';
proc printto log=term;
run;
```

Using SAS System Options to Route Output

Changing the Output Destination Using the LOG, PRINT, ALTLOG, and ALTPRINT System Options

You can use SAS system options to change the destination of the SAS log and procedure output. The options that you use depend on which task you want to accomplish:

- To route your SAS log or procedure output to an external file instead of to their default destinations, use the LOG and PRINT system options.
- To route the log or output to an external file in addition to their default destinations, use the ALTLOG and ALTPRINT system options. This method works in all modes of running SAS.

LOG and PRINT are normally used in batch and interactive line modes. These system options have no effect in the windowing environment. If you are running in the windowing environment, use the ALTLOG and ALTPRINT system options.

You can specify these options in the following locations:

- the SAS command
- a configuration file
- the SASV9_OPTIONS environment variable

For example, you could specify these options in the SAS command as follows:

```sas
sas -log '/u/myid/log' -print '/u/myid/prt'
sas -altlog '/u/myid/log' -altprint '/u/myid/prt'
```

For more information, see "Ways to Specify a SAS System Option" on page 21.
Printing Large Files with the PIPE Device Type in UNIX Environments

When you print a file with the `lp` command, a symbolic link is created from the file to the `/usr/spool` directory. When you pipe output to the `lp` command, the output is copied under the `/usr/spool` directory.

If you experience problems printing large files using the PIPE device type, you can circumvent the problem in either of the following ways:

- save the print file to a disk file and then print it with the `lp` command. Issue the PRINT command from the Output or Log window:
  ```
  print file='bigfile'
  ```
  Exit your SAS session and print the file, or use the SAS X command to print the file from within your SAS session:
  ```
  x 'lp -dmyljsrlt bigfile'
  ```

- create a fileref using the PIPE device type that can handle large files. For example, the following fileref saves the print file to disk, prints the saved file, and then removes the file:
  ```
  filename myfile pipe 'cat >bigfile;lp -dmyljsrlt bigfile;rm bigfile;'
  ```

Changing the Default Print Destination in UNIX Environments

When you print a file, SAS looks in the following locations to determine where to send output. The locations are listed in order of precedence:

1. The destination specified in Universal Printing or the form printer device that you are using. See Universal Printing or forms printing in SAS Language Reference: Concepts for more information.

2. The value specified in the SYSPRINT system option. You can use the SYSPRINT option to set your default print destination. Use the SYSPRINT system option to specify the destination option that is used with your print command. For example, if your print command is `lp`, you can set the default destination to the printer named Myljet by entering the following OPTIONS statement:
   ```
   options sysprint='-dmyljet';
   ```

3. The value of the `$LPDEST` environment variable. For more information, see “Defining Environment Variables in UNIX Environments” on page 285.
SAS uses the first destination that it finds. If you specify a destination in all three locations, SAS uses the destination specified by Universal Printing.

### Changing the Default Print Command in UNIX Environments

UNIX uses `lp` as the default print command. You can use the `PRINTCMD` system option to specify a different print command. For example, you can change your default print command to `lpr` by entering the following at SAS invocation:

```
sas -printcmd "lpr"
```

You can also customize your default print command in your SAS configuration file. If you use this method, then you will not have to change the default print command every time you invoke SAS. For more information, see “PRINTCMD System Option: UNIX” on page 432.

### Controlling the Content and Appearance of Output in UNIX Environments

#### Overview of Controlling the Content and Appearance of Output

Some of the attributes of the SAS log and procedure output depend on the destination to which they are being sent. For example, if the log and output are being sent to your display, the default line and page size are derived from your display. If one or both of these files are sent to the system printer or written to a file, the default line size and page size depend on your printer and page setup. The line size and page size for your current settings can be seen in the Print dialog box.

Some of the attributes of the SAS log and procedure output depend on the mode in which you are running. For example, if you are running in interactive line mode, SAS source statements are not echoed to the SAS log. If you are using the SAS windowing environment, all source statements are written to the log as they are submitted. In batch mode, the log and procedure output are formatted for a standard system printer.

For more information about specifying system options, see “Customizing Your SAS Session By Using System Options” on page 21.
SAS Log Options

Use the following options to control the contents of the log. For more information about specifying options, see “SAS System Options under UNIX” on page 376.

**FULLSTIMER | NOFULLSTIMER**
controls whether a list of resources (such as I/O performed, page faults, elapsed time, and CPU time) used for each PROC or DATA step is written to the log. NOFULLSTIMER is the default.

**LINESIZE=width**
controls the line length used. Width can be any value from 64 to 256.

**NEWS | NONEWS**
controls whether messages are written to the SAS log. NEWS is the default.

**NOTES | NONOTES**
controls printing of NOTES on the log. NOTES is the default setting for all execution modes. Specify NOTES unless your SAS program is completely debugged.

**PAGESIZE=n**
controls the number of lines that are printed on each page. N can be any number from 15 to 32767.

**SOURCE | NOSOURCE**
controls whether SAS source statements are written to the log. NOSOURCE is the default setting in interactive line mode. Otherwise, SOURCE is the default.

**SOURCE2 | NOSOURCE2**
controls whether SAS statements that are included with %INCLUDE statements are written to the log. NOSOURCE2 is the default setting for all execution modes.

**STIMER | NOSTIMER**
controls whether user CPU time and elapsed time are written to the log. STIMER is the default.

Procedure Output Options

Use these system options to control the contents of the procedure output for the LISTING destination:

**CENTER | NOCENTER**
controls whether the printed results are centered or left-aligned on the procedure output page. CENTER is the default.

**DATE | NODATE**
controls whether the date is written at the top of each procedure output page. DATE is the default.

**LINESIZE=width**
controls the line length used. Width can be any value from 64 to 256.
NUMBER | NONUMBER
controls whether the output page number is written on each procedure output page. NUMBER is the default.

PAGENO=n resets the current page number in the print file. The default page number at the beginning of the SAS session is 1. The pages are numbered sequentially throughout the SAS session unless the PAGENO option is specified in an OPTIONS statement during the session.

PAGESIZE=n controls the number of lines that are printed on each page. The value of n can be any number from 15 to 32,767.
Overview of Shared Libraries in SAS

What Is a Shared Library?

Shared libraries in UNIX are libraries that contain executable programs that are written in any of several programming languages. In UNIX, the names of these
programs typically end with a .so or .sl extension. However, they are not constrained to this naming convention.

Shared libraries are a mechanism for storing useful routines that might be needed by multiple applications. When an application needs a routine that resides in an external shared library, it loads the shared library, invokes the routine, and unloads the shared library upon completion.

Invoking Shared Libraries from within SAS

SAS provides routines and functions that let you invoke these external routines from within SAS. You can access the shared library routines from the DATA step, the IML procedure, and SCL code. You use the MODULE family of SAS CALL routines and functions (including MODULE, MODULEN, and MODULEC), as well as the SAS/IML CALL routines and functions (including MODULEIC, MODULEIN, and MODULEI), to invoke a routine that resides in a shared library. This documentation refers to the MODULE family of CALL routines and functions generically as the MODULE function.

For more information, see “CALL MODULE Routine” in SAS Functions and CALL Routines: Reference, “MODULEC Function” in SAS Functions and CALL Routines: Reference, and “MODULEN Function” in SAS Functions and CALL Routines: Reference. For information about MODULEIC, MODULEIN, and MODULEI, see SAS/IML 12.3 User's Guide.

Steps for Accessing an External Shared Library

Use the following steps to access an external shared library routine:

1. Create a text file that describes the shared library routine that you want to access, including the arguments that it expects and the values that it returns (if any). This attribute file must be in a special format, as described in “The SASCBTBL Attribute Table” on page 123.

2. Use the FILENAME statement to assign the SASCBTBL fileref to the attribute file that you created.

3. In a DATA step or SCL code, use the CALL MODULE routine, or the MODULEN or MODULEC functions to invoke the shared library routine. The specific CALL routine or function that you use depends on the type of expected return value (none, numeric, or character). (You can also use MODULEI, MODULEIN, or MODULEIC within a PROC IML step.) The MODULE functions are described in “CALL MODULE Routine: UNIX” on page 300.

CAUTION

Only experienced programmers should access external routines in shared libraries. By accessing a function in a shared library, you transfer processing control to the external function. If done improperly, or if the external function is not reliable, you might lose data, get unreliable results, or receive severe errors.
Introduction to the SASCBTBL Attribute Table

Because the MODULE function invokes an external routine that SAS knows nothing about, provide information about the routine’s arguments. This enables the MODULE function to validate the arguments and convert them, if necessary. For example, suppose you want to invoke a routine that requires an integer as an argument. Because SAS uses floating-point values for all of its numeric arguments, the floating-point value must be converted to an integer before you invoke the external routine. The MODULE function looks for this attribute information in an attribute table that is referred to by the SASCBTBL fileref.

What Is the SASCBTBL Attribute Table?

The attribute table is a sequential text file that contains descriptions of the routines that you can invoke with the MODULE function. The table defines how the MODULE function should interpret supplied arguments when it builds a parameter list to pass to the called routine.

The MODULE function locates the table by opening the file that is referenced by the SASCBTBL fileref. If you do not define this fileref, the MODULE function simply calls the requested shared library routine without altering the arguments.

CAUTION
Using the MODULE function without defining an attribute table can cause SAS to crash, produce unexpected results, or result in severe errors. You need to use an attribute table for all external functions that you want to invoke.

Syntax of the Attribute Table

The Attribute Table

The attribute table should contain the following items:

- a description in a ROUTINE statement for each shared library routine that you intend to call
- descriptions in ARG statements for each argument that is associated with the routine that you intend to call
At any point in the attribute table file, you can create a comment using an asterisk (*) as the first non-blank character of a line or after the end of a statement (following the semicolon). You must end the comment with a semicolon.

ROUTINE Statement

Here is the syntax of the ROUTINE statement:

```
ROUTINE name MINARG=minarg MAXARG=maxarg
   <CALLSEQ=BYVALUE | BYADDR>
   <TRANSPOSE=YES | NO> <MODULE=shared-library-name>
   <RETURNS=DBLPTR | CHAR<n> | DOUBLE | LONG | PTR | SHORT |
     [U]INT32
     | [U]INT64 | ULONG | USHORT>;
```

The following are descriptions of the ROUTINE statement attributes:

**ROUTINE**
starts the ROUTINE statement. You need a ROUTINE statement for every shared library function that you intend to call.

**name**
specifies the routine name. The value for name must match the routine name or ordinal that you specified as part of the module argument in the MODULE function. The module argument is the name of the shared library (if it is not specified by the MODULE attribute) and the routine name or ordinal. For example, in order to specify libc, getcwd in the MODULE function call, set name to getcwd.

The name argument is case sensitive, and is required for the ROUTINE statement.

**MINARG=minarg**
specifies the minimum number of arguments to expect for the shared library routine. In most cases, this value is the same as MAXARG; but some routines do allow a varying number of arguments. This attribute is required.

**MAXARG=maxarg**
specifies the maximum number of arguments to expect for the shared library routine. This attribute is required.

**CALLSEQ=BYVALUE | BYADDR**
indicates the calling sequence method used by the shared library routine. Specify BYVALUE for call-by-value and BYADDR for call-by-address. The default value is BYADDR.

Fortran and COBOL are call-by-address languages. C is usually call-by-value, although a specific routine might be implemented as call-by-address.

The MODULE function does not require that all arguments use the same calling method. You can identify any exceptions by using the BYVALUE and BYADDR options in the ARG statement.

**TRANSPOSE=YES | NO**
specifies whether SAS transposes matrices that have both more than one row and more than one column before it calls the shared library routine. This attribute applies only to routines called from within PROC IML with MODULEI, MODULEIC, and MODULEIN.
TRANSPOSE=YES is necessary when you are calling a routine that is written in a language that does not use row-major order to store matrices. (For example, Fortran uses column-major order.)

For example, consider this matrix with three columns and two rows:

```
columns
  1  2  3
```
```
rows
  1 | 10 11 12
  2 | 13 14 15
```

PROC IML stores this matrix in memory sequentially as 10, 11, 12, 13, 14, 15. However, Fortran routines expect this matrix as 10, 13, 11, 14, 12, 15.

The default value is NO.

**MODULE=** *shared-library-name*

names the executable module (the shared library) in which the routine resides. You do not need to specify this attribute if the name of the shared library is the same name as the routine. If you specify the MODULE attribute in the ROUTINE statement, then you do not need to specify the module name in the module argument in the MODULE function. However, if the shared library routine name that you are calling is not unique in the attribute table, then you must specify this attribute. The MODULE routine is described in “CALL MODULE Routine: UNIX” on page 300.

You can have multiple ROUTINE statements that use the same MODULE name. You can also have duplicate routine names that reside in different shared libraries.

The MODULE function searches the directories that are defined in each operating system's library path environment variable when it attempts to load the shared library argument provided in the MODULE attribute. The following table lists this environment variable for each UNIX operating system that SAS supports.

<table>
<thead>
<tr>
<th>Operating Environment</th>
<th>Environment Variable Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris</td>
<td><code>$LD_LIBRARY_PATH</code></td>
</tr>
<tr>
<td>AIX/R</td>
<td><code>$LIBPATH</code></td>
</tr>
<tr>
<td>HP-UX</td>
<td><code>$LD_LIBRARY_PATH</code> or <code>$SHLIB_PATH</code></td>
</tr>
<tr>
<td>Linux</td>
<td><code>$LD_LIBRARY_PATH</code></td>
</tr>
</tbody>
</table>

**Note:** For more information about these environment variables, see the man pages for your operating environment.

You can also use the PATH system option to point to the directory that contains the shared library specified in the MODULE= option. Using the PATH system option overrides your system's environment variable when you load the shared library. For more information, see “PATH System Option: UNIX” on page 430.
RETURNS=DBLPTR | CHAR<n> | DOUBLE | LONG | PTR | SHORT | [U]INT32 | [U]INT64 | ULONG | USHORT

specifies the type of value that the shared library routine returns. This value is converted as appropriate, depending on whether you use MODULEC (which returns a character) or MODULEN (which returns a number). Here are the possible return value types:

- **DBLPTR**
  pointer to a double-precision floating point number (instead of using a floating-point register). See the documentation for your shared library routine to determine how it handles double-precision floating-point values.

- **CHAR<n>**
  pointer to a character string up to \(n\) bytes long. The string is expected to be null-terminated and is blank-padded or truncated as appropriate. If you do not specify \(n\), the MODULE function uses the maximum length of the receiving SAS character variable.

- **DOUBLE**
  double-precision floating-point number.

- **LONG**
  long integer.

- **PTR**
  character string being returned.

- **SHORT**
  short integer.

- **[U]INT32**
  32-bit unsigned integer.

- **[U]INT64**
  64-bit unsigned integer.

- **ULONG**
  unsigned long integer.

- **USHORT**
  unsigned short integer.

If you do not specify the RETURNS attribute, you should invoke the routine with only the MODULE and MODULEI CALL routines. You will get unpredictable values if you omit the RETURNS attribute and invoke the routine using the MODULEN and MODULEIN functions or the MODULEC and MODULEIC functions.

**ARG Statement**

The ROUTINE statement must be followed by as many ARG statements as you specified in the MAXARG= option. The ARG statements must appear in the order in which the arguments will be specified within the MODULE function.

Here is the syntax for each ARG statement:

```
ARG argnum NUM | CHAR <INPUT | OUTPUT | UPDATE> <NOTREQD | REQUIRED>
    <BYADDR | BYVALUE> <FDSTART> <FORMAT=format>;
```

Here are the descriptions of the ARG statement attributes:
argnum
defines the argument number. This is a required attribute. Define the arguments
in ascending order, starting with the first routine argument (ARG 1).

NUM | CHAR
defines the argument as numeric or character. This attribute is required.

If you specify NUM here but pass the routine a character argument, the
argument is converted using the standard numeric informat. If you specify CHAR
here but pass the routine a numeric argument, the argument is converted using
the BEST12. informat.

INPUT | OUTPUT | UPDATE
indicates the argument is either input to the routine, an output argument, or both.
If you specify INPUT, the argument is converted and passed to the shared library
routine. If you specify OUTPUT, the argument is not converted, but is updated
with an outgoing value from the shared library routine. If you specify UPDATE,
the argument is converted, passed to the shared library routine, and updated
with an outgoing value from the routine.

You can specify OUTPUT and UPDATE only with variable arguments (that is, no
constants or expressions are allowed).

NOTREQD | REQUIRED
indicates whether the argument is required. If you specify NOTREQD, then the
MODULE function can omit the argument. If other arguments follow the omitted
argument, identify the omitted argument by including an extra comma as a
placeholder. For example, to omit the second argument to routine XYZ, you
would specify this code:

call module('XYZ',1,,3);

CAUTION
Be careful when using NOTREQD; the shared library routine must not
attempt to access the argument if it is not supplied in the call to MODULE.
If the routine does attempt to access it, you might receive unexpected
results or severe errors.

The REQUIRED attribute indicates that the argument is required and cannot be
omitted. REQUIRED is the default value.

BYADDR | BYVALUE
indicates whether the argument is passed by reference or by value.

BYADDR is the default value unless CALLSEQ=BYVALUE was specified in the
ROUTINE statement. In that case, BYVALUE is the default. Specify BYADDR
when you are using a call-by-value routine that also has arguments to be passed
by address.

FDSTART
indicates that the argument begins a block of values that are grouped into a
structure whose pointer is passed as a single argument. Note that all subsequent
arguments are treated as part of that structure until the MODULE function
encounters another FDSTART argument.

FORMAT=format
names the format that presents the argument to the shared library routine. Any
formats supplied by SAS, PROC FORMAT style formats, or SAS/TOOLKIT
formats are valid. Note that this format must have a corresponding valid informat
if you specified the UPDATE or OUTPUT attribute for the argument.
The FORMAT= attribute is not required, but is recommended because format specification is the primary purpose of the ARG statements in the attribute table.

**CAUTION**
Using an incorrect format can produce invalid results, cause SAS to crash, or result in serious errors.

---

The Importance of the Attribute Table

The MODULE function relies heavily on the accuracy of the information in the attribute table. If this information is incorrect, unpredictable results can occur (including a system crash).

Consider an example routine *xyz* that expects two arguments: an integer and a pointer. The integer is a code indicating what action takes place. For example, action 1 means that a 20-byte character string is written into the area that is pointed to by the second argument, the pointer.

Suppose you call *xyz* using the MODULE function, but you indicate in the attribute table that the receiving character argument is only 10 characters long:

```sas
routine xyz minarg=2 maxarg=2;
arg 1 input num byvalue format=ib4.;
arg 2 output char format=$char10.;
```

Regardless of the value given by the LENGTH statement for the second argument to MODULE, MODULE passes a pointer to a 10-byte area to the *xyz* routine. If *xyz* writes 20 bytes at that location, the 10 bytes of memory following the string provided by MODULE are overwritten, causing unpredictable results:

```sas
data _null_
  length x $20;
  call module('xyz',1,x);
run;
```

The call might work fine, depending on which 10 bytes were overwritten. However, overwriting can cause you to lose data or cause your system to crash.

Also, note that the PEEKLONG and PEEKCLONG functions rely on the validity of the pointers that you supply. If the pointers are invalid, it is possible that severe errors will result. For example, this code causes an error:

```sas
data _null_
  length c $10;
  /* trying to copy from address 0!!!*/
  c = peekclong(0,10);
run;
```
Special Considerations When Using Shared Libraries

32-Bit and 64-Bit Considerations

Compatibility between Your Shared Libraries and SAS

Starting in SAS 9, SAS is a 64-bit application that runs on all supported UNIX environments that are 64-bit enabled. When you call external routines in shared libraries, the shared library needs to be compatible with SAS.

For example, suppose that you are running SAS 9 on Solaris, which calls routines in the shared library libc.so. The compatible version of this shared library must be 64-bit for SAS 9 to load the library. A 64-bit application cannot load a 32-bit library.

To determine whether a vendor-supplied library is 32-bit or 64-bit, you can use the FILE command. The following output shows the results of using the FILE command on Solaris for a 32-bit and 64-bit library:

```
$ file libc-2.12.so
libc-2.12.so: ELF 64-bit LSB shared object, x86-64, version 1 (GNU/Linux),
dynamically linked (uses shared libs), for GNU/Linux 2.6.18, not stripped

$ file ./libc.so
./libc.so: ELF 64-bit MSB dynamic lib SPARC V9 Version 1, dynamically linked,
not stripped
```

If you have difficulty loading a SAS module that is linked to a vendor-supplied library, check your LD_LIBRARY_PATH environment variable to make sure that it is set up correctly. The environment variable should point to the 64-bit directory of libraries, rather than the 32-bit directory.

Allocated by the Shared Library

When specifying your SAS format and informat for each routine argument in the FORMAT attribute of the ARG statement, you need to consider the amount of memory the shared library allocates for the parameters that it receives and returns. To determine how much storage is being reserved for the input and return parameters of the routine in the external shared library, you can use the SIZEOF C function.

The following table lists the typical memory allocations for C data types for 64-bit systems:
### Table 6.2 Memory Allocations for C Data Types

<table>
<thead>
<tr>
<th>Type</th>
<th>64-Bit System Size (Bytes)</th>
<th>64-Bit System Size (Bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR</td>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>SHORT</td>
<td>2</td>
<td>16</td>
</tr>
<tr>
<td>INT</td>
<td>4</td>
<td>32</td>
</tr>
<tr>
<td>LONG</td>
<td>8</td>
<td>64</td>
</tr>
<tr>
<td>LONG LONG</td>
<td>8</td>
<td>64</td>
</tr>
<tr>
<td>FLOAT</td>
<td>4</td>
<td>32</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>8</td>
<td>64</td>
</tr>
<tr>
<td>POINTER</td>
<td>8</td>
<td>64</td>
</tr>
</tbody>
</table>

For information about the SAS formats to use for your data types, see “Specifying Formats and Informats to Use with MODULE Arguments” on page 135.

### Naming Considerations When Using Shared Libraries

#### Naming Constraints

SAS loads external shared libraries that meet the following naming constraints:

- The name is eight characters or less.
- The name does not contain a period.

If the name of your external shared library is greater than eight characters or contains a period, then you can create a symbolic link to point to the destination of the shared library. Once the link is created, you can add the name of the symbolic link to the MODULE statement in the SASCBTBL attribute table. When you are ready to execute your SAS program, use the PATH system option to point to the directory that contains the symbolic link.

#### Example of Creating a Symbolic Link

The Hewlett-Packard shared library libc.sl that is installed in the `/usr/lib/hpux64` directory contains a period in the name. Before SAS loads this shared library, you need to create a symbolic link that meets the naming convention of eight characters or less and no period. The symbolic link shown in the following example points to the target location of libc.sl:

```
$ ln -s /usr/lib/hpux64/libc.so /tmp/libclnk
```
After the symbolic link is created, you can update the MODULE= option in the SASCBTBL attribute table, as shown in the following code:

```plaintext
routine name minarg=2 maxarg=2 returns=short module=libclnk;
    arg 1 char output byaddr fdstart format=$cstr9.;
    arg 2 char output format=$cstr9.;
```

To load the shared library during your invocation of SAS, enter the following command:

```
/usr/local/sasv94/sas -path /tmp module.sas
```

---

## Using PEEKLONG Functions to Access Character String Arguments

Because the SAS language does not provide pointers as data types, you can use the SAS PEEKLONG functions to access the data stored at these address values.

For example, the following program demonstrates how the address of a pointer is supplied and how it can set the pointer to the address of a static table containing the contiguous integers 1, 2, and 3. It also calls the `useptr` routine in the `useptr` shared library on a 64-bit operating system.

```plaintext
static struct MYTABLE {
    int value1;
    int value2;
    int value3;
} mytable = {1,2,3};

useptr(toset)
    char **toset;
    {
        *toset = (char *)&mytable
    }
```

Here is the SASCBTBL attribute table entry:

```plaintext
routine useptr minarg=1 maxarg=1;
    arg 1 char update format=$char20.;
```

Here is the SAS code:

```plaintext
data _null_
    length ptrval $20 thedata $12;
    call module('*i','useptr',ptrval);
    thedata=peekclong(ptrval,12);

    /* Converts hexadecimal data to character data */
    put thedata=$hex24. ;

    /* Converts hexadecimal positive binary values to fixed or floating point value */
    ptrval=hex40. ;
run;
```

SAS writes the following output to the log.
Log Output for Accessing Character Strings with the PEEKCLONG Function

In this example, the PEEKCLONG function is given two arguments, a pointer via a numeric variable and a length in bytes. PEEKCLONG returns a character string of the specified length containing the characters at the pointer location.

For more information about the PEEKLONG functions, see "PEEKLONG Function: UNIX" on page 323.

Accessing Shared Libraries Efficiently

The MODULE function reads the attribute table that is referenced by the SASCBTBL fileref once per step (DATA step, PROC IML step, or SCL step). It parses the table and stores the attribute information for future use during the step. When you use the MODULE function, SAS searches the stored attribute information for the matching routine and module names. The first time you access a shared library during a step, SAS loads the shared library, and determines the address of the requested routine. Each shared library that you invoke stays loaded for the duration of the step, and is not reloaded in subsequent calls. All modules and routines are unloaded at the end of the step.

In the following example, the attribute table has the following basic form:

* routines XYZ and BBB in FIRST.Shared Library;
  routine XYZ minarg=1 maxarg=1 module=FIRST;
  arg 1 num input;
  routine BBB minarg=1 maxarg=1 module=FIRST;
  arg 1 num input;
* routines ABC and DDD in SECOND.Shared Library;
  routine ABC minarg=1 maxarg=1 module=SECOND;
  arg 1 num input;
  routine DDD minarg=1 maxarg=1 module=SECOND;
  arg 1 num input;

The DATA step code looks like the following:

```sas
filename sascbtbl 'myattr.tbl';
data _null_;
do i=1 to 50;
  /* FIRST.Shared Library is loaded only once */
  value = modulen('XYZ',i);
  /* SECOND.Shared Library is loaded only once */
  value2 = modulen('ABC',value);
  put i= value= value2=;
end;
run;
```

In this example, MODULEN parses the attribute table during DATA step compilation. In the first loop iteration (i=1), FIRST.Shared Library is loaded and the XYZ routine is accessed when MODULEN calls for it. Next, SECOND.Shared Library is loaded and the ABC routine is accessed. For subsequent loop iterations (starting when i=2), FIRST.Shared Library and SECOND.Shared Library remain loaded, so the
MODULEN function simply accesses the XYZ and ABC routines. SAS unloads both shared libraries at the end of the DATA step.

Note that the attribute table can contain any number of descriptions for routines that are not accessed for a given step. The presence of the attribute table does not cause any additional overhead (apart from a few bytes of internal memory to hold the attribute descriptions). In the above example, BBB and DDD are in the attribute table but are not accessed by the DATA step.

Grouping SAS Variables as Structure Arguments

Passing an Argument to a Structure

A common need when calling external routines is to pass a pointer to a structure. Some parts of the structure might be used as input to the routine. Other parts might be replaced or filled in by the routine. Even though SAS does not have structures in its language, you can indicate to the MODULE function that you want a particular set of arguments grouped into a single structure. You indicate this grouping by using the FDSTART option of the ARG statement to flag the argument that begins the structure in the attribute table. SAS gathers that argument and the subsequent arguments (until it encounters another FDSTART option) into a single contiguous block. SAS then passes a pointer to the block as an argument to the shared library routine.

Example: Grouping Your System Information as Structure Arguments

This example uses the `uname` routine, which is part of the `/usr/lib/hpux64/libc.so` shared library in the HP-UX operating environment. This routine returns the following information about your computer system:

- The node name on which you are executing SAS.
- The version of the operating system.
- The vendor of the operating system.
- The computer identification number.
- The model type of your computer.
- The unique identification number of your class of hardware. This value could be a serial number.

Here is the C prototype for this routine:

```c
int uname(struct utsname *name);
```

In C, the `utsname` structure is defined with the following members:

```c
#define UTSLEN 9
#define SNLEN 15

char sysname[UTSLEN];
char nodename[UTSLEN];
char release[UTSLEN];
char version[UTSLEN];
char machine[UTSLEN];
```
char idnumber[SNLEN];

Each of the above structure members are null-terminated strings.

To call this routine using the MODULE function, you use the following attribute table entries:

* attribute table entry;
  routine uname minarg=6 maxarg=6 returns=short module=libc;
  arg 1 char output byaddr fdstart format=$cstr9.;
  arg 2 char output format=$cstr9.;
  arg 3 char output format=$cstr9.;
  arg 4 char output format=$cstr9.;
  arg 5 char output format=$cstr9.;
  arg 6 char output format=$cstr15.;

The following example shows the SAS source code to call the *uname* routine from within the DATA step:

```sql
x 'if [ ! -L ./libc ]; then ln -s /usr/lib/hpux64/libc.so ./libc ; fi' ;
x 'setenv LD_LIBRARY_PATH .:/usr/lib:/lib:/usr/lib/hpux64'

data _null_;
  length sysname $9 nodename $9 release $9 version $9 machine $9 idnumber $15.
  retain sysname nodename release version machine idnumber " ";
  rc=modulen('uname', sysname, nodename, release, version, machine, idnumber)
  put rc = ;
  put sysname = ;
  put nodename = ;
  put release = ;
  put version = ;
  put machine = ;
  put idnumber = ;
run;
```

SAS writes the following output to the log:

**Example Code 6.1** Grouping SAS Variables as a Structure

```
rc=0
sysname=HP-UX
nodename=garage
release=B.11.31
version=u
machine=ia64
idnumber=103901537
```

Using Constants and Expressions as Arguments to the MODULE Function

You can pass any type of expression as an argument to the MODULE function. The attribute table indicates whether the argument is for input, output, or update.

You can specify input arguments as constants and arithmetic expressions. However, because output and update arguments must be able to be modified and returned, you can pass only a variable for them. If you specify a constant or expression where
a value that can be updated is expected, SAS issues a warning message pointing out the error. Processing continues, but the MODULE function cannot perform the update (meaning that the value of the argument that you wanted to update is lost).

Consider these examples. Here is the attribute table:

```
* attribute table entry for ABC;
routine abc minarg=2 maxarg=2;
arg 1 input format=ib4.;
arg 2 output format=ib4.;
```

Here is the DATA step with the MODULE calls:

```
data _null_;
x=5;
/* passing a variable as the    */
/*   second argument - OK       */
call module('abc',1,x);
/* passing a constant as the    */
/*   second argument - INVALID  */
call module('abc',1,2);
/* passing an expression as the */
/*   second argument - INVALID  */
call module('abc',1,x+1);
run;
```

In the above example, the first call to MODULE is correct because \( x \) is updated by the value that the \( abc \) routine returns for the second argument. The second call to MODULE is not correct because a constant is passed. MODULE issues a warning indicating you have passed a constant, and passes a temporary area instead. The third call to MODULE is not correct because an arithmetic expression is passed. Passing an arithmetic expression causes a temporary location from the DATA step to be used and the returned value to be lost.

---

**Specifying Formats and Informats to Use with MODULE Arguments**

**Using the FORMAT Attribute in the ARG Statement**

You specify the SAS format and informat for each shared library routine argument by specifying the FORMAT attribute in the ARG statement. The format indicates how numeric and character values should be passed to the shared library routine and how they should be read back upon completion of the routine.

Usually, the format that you use corresponds to a variable type for a given programming language. The following sections describe the proper formats that correspond to different variable types in various programming languages.

**C Language Formats**
Table 6.3  C Language Formats

<table>
<thead>
<tr>
<th>C Type</th>
<th>SAS Format or Informat for 64-Bit Systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE</td>
<td>RB8.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>FLOAT4.</td>
</tr>
<tr>
<td>SIGNED INT</td>
<td>IB4.</td>
</tr>
<tr>
<td>SIGNED SHORT</td>
<td>IB2.</td>
</tr>
<tr>
<td>SIGNED LONG</td>
<td>IB8.</td>
</tr>
<tr>
<td>CHAR *</td>
<td>IB8.</td>
</tr>
<tr>
<td>UNSIGNED INT</td>
<td>PIB4.</td>
</tr>
<tr>
<td>UNSIGNED SHORT</td>
<td>PIB2.</td>
</tr>
<tr>
<td>UNSIGNED LONG</td>
<td>PIB8.</td>
</tr>
<tr>
<td>CHAR[w]</td>
<td>$CHARw. or $CSTRw. (see &quot;$CSTRw. Format&quot; on page 138 )</td>
</tr>
</tbody>
</table>

Note: For information about passing character data other than as pointers to character strings, see "$BYVALw. Format" on page 139.

Fortran Language Formats

Table 6.4  Fortran Language Formats

<table>
<thead>
<tr>
<th>Fortran Type</th>
<th>SAS Format or Informat</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer*2</td>
<td>IB2.</td>
</tr>
<tr>
<td>integer*4</td>
<td>IB4.</td>
</tr>
<tr>
<td>real*4</td>
<td>RB4.</td>
</tr>
<tr>
<td>real*8</td>
<td>RB8.</td>
</tr>
<tr>
<td>character*w</td>
<td>$CHARw.</td>
</tr>
</tbody>
</table>

The MODULE function can support Fortran character arguments only if they are not expected to be passed by a descriptor.
PL/I Language Formats

Table 6.5 PL/I Language Formats

<table>
<thead>
<tr>
<th>PL/I Type</th>
<th>SAS Format or Informat</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIXED BIN(15)</td>
<td>IB2.</td>
</tr>
<tr>
<td>FIXED BIN(31)</td>
<td>IB4.</td>
</tr>
<tr>
<td>FLOAT BIN(21)</td>
<td>RB4.</td>
</tr>
<tr>
<td>FLOAT BIN(31)</td>
<td>RB8.</td>
</tr>
<tr>
<td>CHARACTER(w)</td>
<td>$CHARw.</td>
</tr>
</tbody>
</table>

The PL/I descriptions are added here for completeness. These descriptions do not guarantee that you will be able to invoke PL/I routines.

COBOL Language Formats

Table 6.6 COBOL Language Formats

<table>
<thead>
<tr>
<th>COBOL Format</th>
<th>SAS Format or Informat</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIC Sxxxx BINARY</td>
<td>IBw.</td>
<td>integer binary</td>

<td>PIC Sxxxx DISPLAY SIGN TRAILING SEPARATE</td>
<td>S370FZDTw.</td>
<td>zoned decimal trailing sign separate</td>
</tr>
<tr>
<td>PIC xxxx BINARY</td>
<td>S370FIBUw.</td>
<td>integer binary unsigned</td>
</tr>
<tr>
<td>PIC xxxx PACKED-DECIMAL</td>
<td>S370FPDUw.</td>
<td>packed decimal unsigned</td>
</tr>
</tbody>
</table>

#### $CSTRw. Format

If you pass a character argument as a null-terminated string, use the $CSTRw. format. This format looks for the last non-blank character of your character argument and passes a copy of the string with a null terminator after the last non-blank character. For example, consider the following attribute table entry:

```
* attribute table entry;
routine abc minarg=1 maxarg=1;
arg 1 input char format=$cstr10.;
```

With this entry, you can use the following DATA step:

```
data _null_;
  rc = module('abc','my string');
run;
```

The $CSTR format adds a null terminator to the character string my string before passing it to the abc routine. Adding a null terminator to the character string and then passing the string to the abc routine is equivalent to the following attribute entry:
attribute table entry;
routine abc minarg=1 maxarg=1;
arg 1 input char format=$char10.;

The entry would have the following DATA step:
```
data _null_;  
  rc = module('abc','my string'||'00'x);  
run;
```
The first example is easier to understand and easier to use when using variable or expression arguments.
The $CSTR informat converts a null-terminated string into a blank-padded string of the specified length. If the shared library routine is supposed to update a character argument, use the $CSTR informat in the argument attribute.

$BYVALw. Format

When you use a MODULE function to pass a single character by value, the argument is automatically promoted to an integer. If you want to use a character expression in the MODULE call, you must use the special format or informat called $BYVALw. The $BYVALw. format and informat expects a single character and produces a numeric value, the size of which depends on w. $BYVAL2. produces a short, $BYVAL4. produces a long, and $BYVAL8. produces a double. Consider this example using the C language:

```c
long xyz(a,b)
    long a; double b;
    {
    static char c = 'Y';
    if (a == 'X')
        return(1);
    else if (b == c)
        return(2);
    else return(3);
    }
```
In this example, the `xyz` routine expects two arguments, a long and a double. If the long is an x, the actual value of the long is 88 in decimal. This result happens because an ASCII X is stored as hexadecimal 58, and this value is promoted to a long, represented as 0x00000058 (or 88 decimal). If the value of a is x, or 88, then a 1 is returned. If the second argument, a double, is y (which is interpreted as 89), then 2 is returned.

If you want to pass characters as the arguments to `xyz`, then in the C language, you would invoke them as follows:

```c
x = xyz('X',(double)'Z');
y = xyz('Q',(double)'Y');
```
The characters are invoked in this way because the x and Q values are automatically promoted to integers. (Integers are the same as longs in this example.) The integer values corresponding to Z and Y are cast to doubles.

To call `xyz` using the MODULEN function, your attribute table must reflect the fact that you want to pass characters:
```
routine xyz minarg=2 maxarg=2 returns=long;
arg 1 input char byvalue format=$byval4.;
arg 2 input char byvalue format=$byval8.;
```
Note that it is important that the BYVALUE option appears in the ARG statement as well. Otherwise, MODULEN assumes that you want to pass a pointer to the routine, instead of a value.

Here is the DATA step that invokes MODULEN and passes it characters:

```sas
data _null_;  
x = modulen('xyz','X','Z');  
put x= ' (should be 1)';  
y = modulen('xyz','Q','Y');  
put y= ' (should be 2)';  
run;
```

**Understanding MODULE Log Messages**

If you specify i in the control string parameter to MODULE, SAS prints several informational messages to the log. You can use these messages to determine whether you have passed incorrect arguments or coded the attribute table incorrectly.

Consider this example that uses MODULEIN from within the IML procedure. It uses the MODULEIN function to invoke the `changi` routine (which is stored in theoretical TRYMOD.so). In the example, MODULEIN passes the constant 6 and the matrix x2, which is a 4x5 matrix to be converted to an integer matrix. The attribute table for `changi` is as follows:

```sas
routine changi module=trymod returns=long;  
arg 1 input num format=ib4. byvalue;  
arg 2 update num format=ib4.;
```

The following IML step invokes MODULEIN:

```sas
proc iml;  
x1 = J(4,5,0);  
do i=1 to 4;  
  do j=1 to 5;  
    x1[i,j] = i*10+j+3;  
  end;  
end;  
y1= x1;  
x2 = x1;  
y2 = y1;  
rc = modulein('*i','changi',6,x2);  
....
```

The `*i` control string causes the lines shown in the following output to be written in the log.
The output is divided into four sections:

- The first section describes the arguments passed to MODULEIN.
  
The CHR PARM n portion indicates that character parameter n was passed. In the example, 885E0AA8 is the actual address of the first character parameter to MODULEIN. The value at the address is hexadecimal 2A69, and the ASCII representation of that value ("\*i") is in parentheses after the hexadecimal value. The second parameter is printed similarly. The ASCII equivalents are printed for only these first two arguments because other arguments might contain unreadable binary data.

  The remaining parameters appear with only hexadecimal representations of their values (NUM PARM 3 and NUM PARM 4 in the example).

  The third parameter to MODULEIN is numeric, and it is at address 885E0AE0. The hexadecimal representation of the floating-point number 6 is shown. The fourth parameter is at address 885E07F0, which points to an area containing all the values for the 4x5 matrix. The \*i option prints the entire argument. Be careful if you use this option with large matrices, because the log might become quite large.

- The second section of the log lists the arguments that are to be passed to the requested routine and, in this case, changed. This section is important for determining whether the arguments are being passed to the routine correctly. The first line of this section contains the name of the routine and its address in memory. It also contains the address of the location of the parameter block that MODULEIN created.

  The log contains the status of each argument as it is passed. For example, the first parameter in the example is call-by-value (as indicated in the log). The second parameter is the address of the matrix. The log shows the address, along with the data to which it points.

  Note that all the values in the first parameter and in the matrix are long integers because the attribute table states that the format is IB4.
In the third section, the log contains the argument values upon return from `changi`. The call-by-value argument is unchanged, but the other argument (the matrix) contains different values.

The last section of the log output contains the values of the arguments as they are returned to the MODULEIN CALL routine.

Examples of Accessing Shared Executable Libraries

Example 1: Updating a Character String Argument

This example uses the `tmpnam` routine in the shared library provided by Solaris, `libc.so`, which is installed in the `/usr/lib/64` directory. The `tmpnam` routine generates a unique filename that can be used safely as a temporary filename. The temporary filename is typically placed in the `/var/tmp` directory.

Here is the C prototype for this routine:

```c
char * tmpnam(char *s);
```

The attribute table for this prototype would be the following:

```
routine tmpnam minarg=1 maxarg=1 returns=char255. module=libc;
arg 1 char output byaddr format=$cstr255;
```

The SAS source code would be the following:

```
x 'if [ ! -L ./libc ] ; then ln -s /usr/lib/64/libc.so.1 ./libc ; fi' ;
x 'setenv LD_LIBRARY_PATH .:/usr/lib/64/usr/lib:/lib';
data _null_
  length tempname $255 tname $255;
  retain tempname tname " ";
  tname = modulec ('tmpnam', tempname);
  put tempname = ;
  put tname = ;
run;
```

The SAS log would display the following information:

**Example Code 6.3  Updating a Character String Argument**

```
tempname=/var/tmp/aaaKraydG
tname=/var/tmp/aaaKraydG
```

The POSIX standard for the maximum number of characters in a pathname is defined in `/usr/include/limits.h` as 255 characters. This example uses 254 as the length of the generated filename (`tempname`) with one character reserved for the null terminator. The `$CSTR255.` informat ensures that the null terminator and all subsequent characters are replaced by trailing blanks when control returns to the DATA step.
Example 2: Passing Arguments by Value

This example calls the `access` routine that is supplied by most UNIX vendors. This particular `access` routine is in the Hewlett-Packard shared library, libc.sl, which is installed in the `/usr/lib/hpux64` directory.

Here is the C prototype for this routine:

```c
int access(char *path, int amode);
```

The `access` routine checks the file that is referenced by the accessibility path according to the bit pattern contained in `amode`. You can use the following integer values for `amode` that correspond to the types of permission for which you are testing:

- 4   Read access
- 2   Write access
- 1   Execute (search) access
- 0   Check existence of file

A return value of 0 indicates a successful completion, and the requested access is permitted. A return value of -1 indicates a failure, and the requested access is not permitted.

Because the `amode` argument is a pass-by-value, this example includes the BYVALUE specification for `arg 2` in the attribute table. If both arguments were pass-by-values, one could use the CALLSEQ=BYVALUE attribute in the ROUTINE statement, and it would not be necessary to specify the BYVALUE option in `arg 2`.

The attribute table would be the following:

```c
routine access minarg=2 maxarg=2 returns=short module=libc;
arg 1 char input byaddr format=$cstr200.;
arg 2 num input byvalue format=ib4.;
```

The SAS source code would be the following:

```sas
x 'if [ ! -L ./libc ] ; then ln -s /usr/lib/hpux64/libc.so ; fi' ;
x 'setenv LD_LIBRARY_PATH ./:usr/lib/hpux64:/usr/lib:/lib' ;

data _null_;
length path $200.;
path='/dev';
/* A non-root user is testing for write permission in the /dev directory */
rc = modulen("*ie","access",path,2);
put rc = ;
run;
```

The SAS log output would be the following:

**Example Code 6.4  Results If Request Access Is Permitted**

```
rc=-1
```

If you changed the SAS source code to check for a Write permission in the user’s `$HOME` directory, the output would be different:

```sas
data _null_;
length homedir $200.;
homedir=sysget('HOME');

/* A user is testing for write permissions in their $HOME directory */
rc = modulen("*ie", 'access', homedir, 2);
put rc = ;
run;

In this case, the SAS log output would be the following:

**Example Code 6.5  Results for Successful Completion (Access Permitted)**

**Example 3: Using PEEKCLONG to Access a Returned Pointer**

This example uses the *strcat* routine, which is part of the Red Hat Linux shared library libc-2.12.so. This library is typically installed in the /lib64 directory. This routine concatenates two strings and returns a pointer to the newly concatenated string.

Here is the C prototype for this routine:

```c
char *strcat(char, *dest, const char *src);
```

The proper SASCBTBL attribute table would be the following:

```sas
routine strcat minarg=2 maxarg=2 returns=ulong module=libc;
arg 1 char input format=$cstr200.;
arg 2 char input format=$cstr200.;
```

The following example shows the SAS code:

```sas
filenamesascbtbl './sascbtbl.txt';

data _null_;
  file sascbtbl;
  put "routine strcat minarg=2 maxarg=2 returns=ulong module=libc;";
  put "arg 1 char input format=$cstr200.;";
  put "arg 2 char input format=$cstr200.;";
run;

data _null_;  
  length string1 string2 newstring $200;  
  length chptr $20;
  string1='This is string one and';
  string2=' this is string two. ';
  chptr=modulec('strcat', string1, string2);
  newstring=peekclong(chptr, 200);
  put newstring=;
run;
```

SAS writes the following output to the log:
Example Code 6.6  Results from Using PEEKCLONG to Access a Returned Pointer

newstring=This is string one and this is string two.

For more information about the PEEKLONG and PEEKCLONG functions, see “PEEKLONG Function: UNIX” on page 323 and “PEEKCLONG Function” in SAS Functions and CALL Routines: Reference.

Example 4: Using Structures

“Grouping SAS Variables as Structure Arguments” on page 133 describes how to use the FDSTART attribute to pass several arguments as one structure argument to a shared library routine. The passing of several arguments as one structure is another example of using structures with another routine in an external shared library.

The statvfs routine that is available under most UNIX operating systems retrieves file system information. This example uses the statvfs routine that is in the Solaris libc.so.1 shared library and typically installed in the /usr/lib/sparcv9 directory.

Here is the C prototype for this routine:

```c
int statvfs(const char *path, struct statvfs *buf);
```

The `statvfs` routine returns a 0 if the routine completes successfully and –1 if there is a failure.

The `statvfs` structure is defined with the following members:

```
unsigned long f_bsize;          /* preferred file system block size */
unsigned long f_frsize;         /* fundamental file system block */
unsigned long f_blocks;         /* total number of blocks on file system in units */
unsigned long f_bfree;          /* total number of free blocks */
unsigned long f_bavail;         /* number of free blocks available to non-superuser */
unsigned long f_files;          /* total number of file nodes (inodes) */
unsigned long f_ffree;          /* total number of free file nodes */
unsigned long f_favail;         /* number of inodes available to non-superuser */
unsigned long f_fsid;           /* file system id (dev for now) */
char          f_basetype[16];   /* target fs type name, null-terminated */
unsigned long f_flag;           /* bit mask of flags */
unsigned long g_f_namemax;      /* maximum filename length */
char          f_fstr[32];       /* file system specific string */
```

The SASCBTBL attribute table would be the following:

```
routine statvfs
  minarg=14
  maxarg=14
  returns=short
  module=libc;
  arg 1 char input byaddr format=$char256.;
  arg 2 num output byaddr fdstart format=pib8.;
  arg 3 num output format=pib8.;
  arg 4 num output format=pib8.;
  arg 5 num output format=pib8.;
  arg 6 num output format=pib8.;
  arg 7 num output format=pib8.;
```
arg 8 num output format=pib8.;
arg 9 num output format=pib8.;
arg 10 num output format=pib8.;
arg 11 char output format=$cstr16.;
arg 12 num output format=pib8.;
arg 13 num output format=pib8.;
arg 14 char output format=$cstr32.;

The SAS source code to call the `statvfs` routine from within the DATA step would be the following:

```sas
x 'if [ ! -L ./libc ]; then ln -s /usr/lib/sparcv9/libc.so.1 ./libc ; fi' ;
x 'setenv LD_LIBRARY_PATH .:/usr/lib/sparcv9:/usr/lib:/lib';

data _null_;
  length f_basetype $16. f_fstr $32.;
  retain f_bsize f_frsize f_blocks f_bfree f_bavail f_files f_ffree f_favail
    f_fsid f_flag f_namemax 0;
  retain f_basetype f_fstr ' ';
  rc=modulen ('statvfs', '/tmp', f_bsize, f_frsize, f_blocks, f_bfree, f_bavail,
    f_files, f_ffree, f_favail, f_fsid, f_basetype, f_flag,
    f_namemax, f_fstr);
  put rc = ;
  put f_bsize = ;
  put f_frsize = ;
  put f_blocks = ;
  put f_bfree = ;
  put f_bavail = ;
  put f_files = ;
  put f_ffree = ;
  put f_favail = ;
  put f_fsid = ;
  put f_basetype = ;
  put f_flag = ;
  put f_namemax = ;
/* Determining the total bytes available in the file system and then dividing the
   total number of bytes by the number of bytes in a gigabyte */
gigsfree = ((f_bavail * f_bsize)/1073741824);
  put 'The total amount of space available in /tmp is 'gigsfree 4.2' Gigabytes.';
run;
```

The SAS log output would be the following:

**Example Code 6.7  Log Output for Using Structures**

```
rc=0
f_bsize=8192
f_frsize=8192
f_blocks=196608
f_bfree=173020
f_bavail=173020
f_files=884732
f_ffree=877184
f_favail=877184
f_fsid=2
f_basetype=tmpfs
f_flag=4
f_namemax=255

The total amount of space available in /tmp is 1.32 Gigabytes.
```
Example 5: Invoking a Shared Library Routine

This example shows how to pass a matrix as an argument within PROC IML. The example creates a 4x5 matrix. Each cell is set to 10x+y+3, where x is the row number and y is the column number. For example, the cell at row 1 column 2 is set to (10*1)+2+3, or 15.

The example invokes several routines from the theoretical TRYMOD shared library. It uses the changd routine to add 100x+10y to each element, where x is the C row number (0 through 3) and y is the C column number (0 through 4). The first argument to changd specifies the extra amount to sum. The changdx routine works just like changd, except that it expects a transposed matrix. The changi routine works like changd except that it expects a matrix of integers. The changix routine works like changdx except that integers are expected.

Note: A maximum of three arguments can be sent when invoking a shared library routine from PROC IML.

In this example, all four matrices x1, x2, y1, and y2 should become set to the same values after their respective MODULEIN calls. Here are the attribute table entries:

- **routine changd** module=trymod returns=long;
  
  arg 1 input num format=rb8. byvalue;
  
  arg 2 update num format=rb8.;

- **routine changdx** module=trymod returns=long
  
  transpose=yes;
  
  arg 1 input num format=rb8. byvalue;
  
  arg 2 update num format=rb8.;

- **routine changi** module=trymod returns=long
  
  arg 1 input num format=ib4. byvalue;
  
  arg 2 update num format=ib4.;

- **routine changix** module=trymod returns=long
  
  transpose=yes;
  
  arg 1 input num format=ib4. byvalue;
  
  arg 2 update num format=ib4.;

Here is the PROC IML step:

```iml
proc iml;
  x1 = J(4,5,0);
  do i=1 to 4;
    do j=1 to 5;
      x1[i,j] = i*10+j+3;
    end;
  end;
  y1 = x1; x2 = x1; y2 = y1;
  rc = modulein('changd',6,x1);
  rc = modulein('changdx',6,x2);
  rc = modulein('changi',6,y1);
  rc = modulein('changix',6,y2);
  print x1 x2 y1 y2;
run;
```

Here are the results of the PRINT statement:
Output 6.2  Invoking a Shared Library Routine from PROC IML

What Is Remote Browsing?

Remote browsing enables you to view SAS documentation, URLs that are specified in the WBROWSE command, and ODS output in the web browser on your local computer. In the past, all web documentation was displayed by executing your browser on the SAS server. By displaying this documentation locally, you have faster access to the documentation and you free up resources on the SAS server that were used by your browser.

A small software agent called the remote browser server runs on your local computer. When SAS needs to display HTML content, it connects to the remote browser server and sends the URL that references the content. The remote browser server then passes the URL to a browser for display. If the remote browser server is not running on your computer, SAS displays a dialog box that contains the URL that you need to use to download the remote browser server.

Two system options are provided to configure remote browsing: HELPHOST and HELPPORT. These options specify the host name and port number of the computer where HTML content is to be displayed. In most cases, these options do not need to be set. HELPHOST defaults to the host name that is specified in the X11 DISPLAY environment variable. Alternatively, if the client connects to the UNIX host by using SSH with X11 forwarding enabled, HELPHOST defaults to the IP address that is specified in the SSH_CLIENT environment variable. HELPPORT defaults to the standard port for the remote browser server.
Using Remote Browsing with ODS Output

The SAS Output Delivery System (ODS) can be used to generate graphical reports of your SAS data. Remote browsing enables you to view your output directly from a SAS session as the output is generated or on demand from the Results window.

Remote browsing displays ODS output in many formats. If your browser does not have the appropriate plug-in for output that is not HTML, the browser displays a dialog box rather than the output. This dialog box enables you to download your output to your computer and view it using a local program such as Excel for an XSL file.

The automatic display of ODS output (HTML, PDF, and RTF only) is turned off by default. You can turn on the automatic display of ODS output by issuing the AUTONAVIGATE command in the Results window or by selecting View results as they are generated from the Results tab of the Preferences dialog box.

Installing the Remote Browser Server

You can install the remote browser server directly from your SAS session. If SAS is unable to make a connection for remote browsing, SAS displays a dialog box that contains the URL that you need to download the installer. Use this URL to download and install the remote browser server. Do not exit SAS. To install the remote browser server, follow these steps:

1. Type the URL that appears in the dialog box into your browser and press Enter, or use the Copy URL button in the dialog box to copy the URL, and then paste it into your browser.

2. After the download page is displayed, download the installer that is appropriate for your computer.

3. Run the installer.
   - In the Windows environment, the remote browser server is added to your start-up items, so that the server starts whenever you log on. An icon is displayed in your system tray to indicate that the remote browser server is running.
   - In the Linux environment, manually add the command rbrowser to the start-up script for your windowing environment. The remote browser server will initially run minimized.
System Options for Remote Browsing

After the remote browser server is running on your computer, you can run the remote browsing system by specifying the HELPHOST and HELPPORT system options.

- The HELPHOST system option specifies the name of your host computer where the remote browsing system is to be displayed. If you do not specify this option, then the host name specified in the X display name is used. For more information, see “HELPHOST System Option: UNIX” on page 406.

- The HELPPORT system option specifies the port number for the remote browser server that is installed on your computer. Under UNIX, you can use the default value for this option. For more information, “HELPPORT= System Option” in SAS System Options: Reference.

You can set these options in your configuration file, at SAS invocation, or during your SAS session in the OPTIONS statement or in the SAS System Options window.

Setting Up the SAS Remote Browser

Setting Up the SAS Remote Browser at SAS Invocation

The following syntax is specific for UNIX operating environments and shows how you might set up the SAS Remote Browser if your remote browser server is using network port 12000:

```
sas94 -helpport 12000
```

Because you did not specify the HELPHOST system option, SAS uses the host name that is specified in the X display name.

Setting Up the SAS Remote Browser during a SAS Session

The syntax in this example applies to UNIX environments.

You can set up the remote browsing system during a SAS session by using the OPTIONS statement or the SAS System Options window. The following example uses the OPTIONS statement to change the value of the HELPPORT system option:

```
options helpport=12000;
```

Because you did not specify the HELPHOST system option, its value remains unchanged.
Remote Browsing and Firewalls

For General Users

If your network has a firewall between desktop computers and the computer that is hosting SAS, web browsers cannot display web pages from your SAS session. Usually, this problem is indicated by a time-out or connection error from the web browser. If you receive a time-out or connection error, contact your system administrator.

For System Administrators

To enable the display of web pages when a firewall exists between desktop computers and the computer that is hosting SAS, a firewall rule that allows a web browser to connect to SAS must be added. The firewall rule specifies a range of network ports for which SAS remote browsing connections are allowed. Contact the appropriate system administrator who can select and configure a range of network ports for remote browsing. The range depends on the number of simultaneous SAS users. A value of approximately three times the number of simultaneous SAS users should reserve a sufficient number of network ports.

After the firewall rule is added, SAS must be configured to listen for network connections in the network port range. Normally, SAS selects any free network port, but the HTTPSERVERPORTMIN and the HTTPSERVERPORTMAX system options limit the network ports that SAS can select. Add these system options to your SAS configuration file. Set HTTPSERVERPORTMIN to the lowest port in the network range. Set HTTPSERVERPORTMAX to the highest port in the network range. For example, if the system administrator defined a network port range of 8000 to 8200, the system options would be the following:

httpserverportmin=8000
httpserverportmax=8200

After these system options are set, desktop computers can display web pages. If there is an insufficient number of network ports, or the system options are specified incorrectly, a message appears in the SAS log.

For more information about these system options, see “HTTPSERVERPORTMIN= System Option” in SAS System Options: Reference and “HTTPSERVERPORTMAX= System Option” in SAS System Options: Reference.
Performance Considerations under UNIX

Configure Your Environment Based on SAS Tuning Guidelines

SAS System Option Guidelines

For the best performance in a UNIX environment, verify that SAS system options are set based on SAS tuning guidelines. You can find these guidelines in Usage Note 46954. This usage note is updated as needed. Typically, these setting recommendations are the default settings for SAS system options.

Operating System Tuning Guidelines

You can achieve better performance by following SAS recommendations for UNIX operating systems. Usage Note 53873 contains the current operating system tuning guidelines. This usage note is updated as needed.
Guidelines for the SAS Middle Tier and SAS Web Application Server

For information about tuning values for the SAS middle tier and SAS Web Application Server, see SAS Web Applications: Tuning for Performance and Scalability in the SAS Intelligence Platform documentation.

Measure the I/O Throughput of a File System

When troubleshooting performance problems, be aware that SAS processes place different demands on file systems and I/O throughput than traditional databases or simple query processes. For that reason, you need to be able to determine the I/O throughput rates of any file system that SAS uses.

SAS has a shell script, iotest.sh, that system administrators and IT teams can use to test I/O throughput. For information about usage and I/O throughput targets, see Usage Note 53876.

Definition of the SAS Windowing Environment

The SAS windowing environment refers to the windows that open when you invoke SAS. These windows include: the Program Editor, Log, Output, Explorer, and Results. These windows appear when you start SAS from your X workstation or through an X emulator. For more information about these windows, see the online SAS Help and Documentation.

The SAS windowing environment supports the use of X-based graphical user interfaces (GUIs). In UNIX environments, SAS provides an X Window System interface that is based on the Motif style.

Many features of the SAS windowing environment are controlled by X resources. For example, colors, window sizes, the appearance of the SAS ToolBox, and key definitions are all controlled through X resources. Chapter 10, “Customizing the SAS Windowing Environment,” on page 185 provides general information about resources, such as how to specify resources, and describes all of the resources that you can use to customize the interface.
Description of SAS in the X Environment

Definition of X Window System

The X Window System is a networked windowing system. If several computers are on a network, you can run an X server that, in turn, serves X applications (as clients) from all the other computers in the network.

X Window Managers

In UNIX environments, SAS features an X Window System interface that is based on Motif. This interface uses the window manager on your system to manage the windows on your display. Any window manager that is compliant with the Inter-Client Communication Conventions Manual (ICCCM) can be used with the Motif interface to SAS. Vendors provide at least one window manager with the X Window System environment. A common window manager is the GNOME. KDE is an alternative window manager. You should read the documentation that is supplied by the vendor for the window manager that you are using.

All window managers perform the same basic functions, but they differ in their style and in their advanced functions. The appearance and function of the interface to SAS depends to some extent on your X window manager. Most window managers provide some type of frame around a window. The window manager also governs the placement, sizing, stacking, and appearance of windows, as well as their interaction with the keyboard. The basics of interacting with SAS are the same for all window managers: opening menus, moving windows, responding to dialog boxes, dragging text, and so on.

SAS Window Session ID

When you run SAS on an X workstation, SAS shares the display with other X applications, including other SAS sessions. To distinguish between different applications and SAS sessions, SAS generates a SAS window session ID for each session by appending a number to the application name. The default application name is SAS. This session ID appears in the window title bar for each SAS window and in the window icon title. The SAS sessions are assigned sequentially. Your first SAS session is not assigned a number, so the session ID is SAS; your second SAS session is assigned the session ID SAS2, and so on. Although the default application name is SAS, you can use the -name X option or the -title X option to change the instance name. The instance name can be up to 64 characters long and is displayed in the case in which it was entered, which can be lowercase, mixed case, or uppercase.
Workspace and Gravity in a SAS Session

When you use SAS on an X workstation, the display might be shared by many concurrent applications. When SAS windows from different sessions and windows from other applications appear on the display, the display can become cluttered. To help alleviate this problem, the windows for a SAS session first appear within an application workspace (AWS). The AWS defines a rectangular region that represents a virtual display in which SAS windows are initially created. SAS attempts to position the AWS in relation to the upper left corner of your display. In other words, the workspace gravitates toward a certain direction (session gravity) on the display. Some window manager configurations might override the placement that SAS has chosen for a window.

If you issue windowing commands or execute SAS procedures that create new SAS windows, the same rules of initial position and size apply to these windows: they are initially placed in the SAS AWS. You can use the WSAVE command to save the current window positions (or geometry). For more information, see "Customizing Session Workspace, Session Gravity, and Window Sizes in UNIX Environments" on page 231.

Window Types

Top-Level Windows

SAS uses primary and interior windows. Some SAS applications consist of one or more primary windows controlled by the X window manager, in addition to the interior windows controlled by SAS. The SAS windowing environment primary windows, as well as most SAS application windows, initially appear as top-level windows. Top-level windows interact directly with the X window manager. They have a full title bar along with other window manager decorations. You can manipulate them individually after they appear on the display.

Interior Windows

Interior windows behave differently from primary windows. SAS/ASSIST software is an application with interior windows. Interior windows are contained within container windows, which might not be primary windows. The following display shows an interior window in SAS/ASSIST software.
SAS provides some degree of window management for interior windows. Specifically, interior windows have the following sizing and movement capabilities:

- You can move interior windows by clicking the interior window title bar and dragging the window to the desired location. If the destination of the interior window is outside the bounds of the container window, the container window changes according to the value of the `SAS.awsResizePolicy` resource. (The space within the container window is the application workspace, which is described in "Workspace and Gravity in a SAS Session" on page 160.) For more information, see "Overview of X Resources" on page 186.

- Interior windows cannot be minimized individually. Clicking on the container window icon button minimizes the container window and its interior windows.

- A push-to-back button (the small overlapping squares in the upper right corner) is available with interior windows. However, you cannot push an active window behind an inactive window.

---

The SAS Session Manager (motifxsassm) in UNIX

What Is the SAS Session Manager?

The SAS Session Manager for X (motifxsassm) is an X client that is run by SAS when you use the SAS windowing environment. The SAS Session Manager is automatically minimized when you start SAS. The SAS: Session Management dialog box for the SAS Session Manager appears as shown in the following display:
The SAS: Session Management dialog box lists the following information:

- which SAS session it controls
- the host computer from which the SAS session was invoked
- the UNIX process identifier of the SAS session

**Features of the SAS Session Manager**

The buttons in the SAS: Session Management dialog box enable you to do the following tasks:

- **Minimize**
  maps and minimizes all windows of the SAS session. This function is performed with standard X library calls and works with most X window managers.

- **Restore**
  restores all of the windows that are open in the SAS session that is controlled by that SAS Session Manager. This function is performed with standard X library calls and works with most X window managers.

- **Interrupt**
  sends a UNIX signal to SAS. When SAS receives the signal, it displays the Tasking Manager dialog box. (See “Interrupting a SAS Session” on page 162).

- **Terminate**
  displays a dialog box that asks you to confirm whether you want to terminate the SAS session.

- **Help**
  provides Help for the SAS: Session Management dialog box.

**Interrupting a SAS Session**

When you click **Interrupt** in the SAS: Session Management dialog box, and if no PROC or DATA step is executing, the following Tasking Manager dialog box appears:
If a PROC or DATA step is executing, the following Tasking Manager dialog box appears:

Click one of the following buttons in the Tasking Manager dialog box:

1. causes the current PROC or DATA step statements to be deleted.

2. causes the current PROC or DATA step to receive a request to interrupt processing. You are prompted to confirm this action.

C. closes the dialog box without affecting SAS processing.

T. forces SAS to terminate the SAS session. You are prompted to confirm termination.

The following Confirm Termination dialog box appears:
If you click **OK**, the SAS Session Manager sends a UNIX signal to the SAS session that forces the session to terminate.

**CAUTION**

Terminating your SAS session might result in data loss or data corruption. Before terminating your SAS session, you should attempt to end SAS using one of the methods described in “Methods for Exiting SAS” on page 30.

---

**Using the Host Editor from within Your SAS Session**

When you issue the HOSTEDIT command, SAS passes the request to the SAS Session Manager, which then invokes your host editor. The SAS Session Manager must be running for the HOSTEDIT command to take effect. When you issue the HOSTEDIT command, SAS creates a temporary file that contains the data from the active SAS window and passes this file to your host editor. (These temporary files are stored in the directory specified by the SAS WORK option.) When you save your file in the host editor, the file is copied back into the SAS window if the window is able to be written to. The temporary files are deleted when the SAS session ends. For more information, see “Configuring SAS for Host Editor Support in UNIX Environments” on page 183.

---

**Closing the SAS Session Manager**

If you close the SAS: Session Management dialog box, you cannot retrieve the SAS Session Manager. To display the SAS Session Manager again, you can reinvoke `!SASROOT/utilities/bin/motifxsassm` with the `-pid` or the `-sessionid` arguments. Execute these commands at the UNIX prompt or use them with the X statement:

```
!SASROOT/utilities/bin/motifxsassm -pid pid
!SASROOT/utilities/bin/motifxsassm -sessionid integer
```

---

**Disabling the SAS Session Manager**

You can disable the SAS Session Manager in the following ways:

- Select **Tools** ⇒ **Options** ⇒ **Preferences**.
  
  On the **General** tab, deselect the **Start Session manager** check box.

- Specify the following X resource, in lowercase, on the SAS command line at invocation:
  
  ```
sas -xrm 'SAS.startSessionManager: False'
  ```

Specifying the `sas.startSessionManager` X resource deselects the **Start Session manager** check box in the Preferences dialog box.
Note: SAS saves the settings in the Preferences dialog box when it exits. If you have disabled the SAS Session Manager during your session, then the next time you invoke SAS, the SAS Session Manager will not run. To start the SAS Session Manager, select the Start Session manager check box in the Preferences dialog box. Alternatively, specify the following command in lowercase on the SAS command line at invocation:

```
sas -xrm 'SAS.startSessionManager: True'
```

Displaying Function Key Definitions in UNIX Environments

Benefits of Assigning Function Key Definitions

Function keys provide quick access to commands. They enable you to issue commands, insert text strings, and insert commands in programs. Function key definitions can be different on different terminals. These definitions can be fully customized.

How to Display Function Key Definitions

You can open the KEYS (DMKEYS) window to display all of your function key definitions in one of the following ways:

- Press F2.
- Issue the KEYS command.
- Select Tools ⇒ Options ⇒ Keys.

To view a single key definition without bringing up the KEYS window, use the KEYDEF command and specify the key definition that you want to view. For example, the following command displays the definition for key F4:

```
keydef f4
```

<table>
<thead>
<tr>
<th>Key or Key Combination</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>F1</td>
<td>Help</td>

The SAS ToolBox in UNIX Environments

Introduction to the SAS ToolBox

The SAS ToolBox has two parts as illustrated in the following display:

Figure 9.6  The SAS ToolBox

- A command window that enables you to quickly enter any command in the active SAS window. For information about commands that are available under UNIX, see “SAS Commands under UNIX” on page 250 and the SAS commands section in the Base SAS section in the online SAS Help and Documentation.

- A toolbar that contains several tool icons. When you select a tool icon, SAS immediately executes the command that is associated with that icon. You can customize both the toolbar and the tool icons. For more information, see “Using the Tool Editor” on page 202.

The name of the active window is displayed in the title bar of the SAS ToolBox. For example, if the Log window were active, the title bar would say SAS ToolBox: Log instead of SAS ToolBox: Program Editor.

Under UNIX, the default SAS ToolBox automatically appears at the bottom of the SAS windows stack by default. To control its configuration, you use the Preferences dialog box. (See “Modifying the SAS ToolBox Settings” on page 193.)

Customizing the Default SAS ToolBox

The default SAS ToolBox is automatically copied to your $SASUSERPROFILE.DMS.Toolbox regardless of whether you customize the ToolBox. If you invoke an application that does not have an associated PMENU entry, the default toolbox is displayed for that application. If you then customize the toolbox for...
that application, the customized toolbox is stored in Sasuser.Profile.Default.Toolbox. In Sasuser.Profile.Default.Toolbox, DEFAULT is the same entry name as the PMENU entry for the window or application.

You can customize the default SAS ToolBox, create multiple toolboxes and switch between them, and create application-specific toolboxes (such as with SAS/AF applications) that are automatically loaded when the application is loaded. Only one toolbox is displayed at a time, and the tools in the toolbox change as you move between applications. For more information, see “Customizing Toolboxes and Toolsets in UNIX Environments” on page 201.

Default Configuration for the Command Window and the Toolbar

By default, the toolbar and the command window are joined and are automatically displayed when SAS initializes unless one of the following conditions applies:

- You executed your SAS job in a non-windowing environment mode.
- The SAS.defaultToolBox or SAS.defaultCommandWindow resource is set to False. The default value is True. For more information about the resources that control the toolbox, see “X Resources That Control Toolbox Behavior” on page 201.
- You deselect Display tools window, Display command window, or Combine windows from the ToolBox tab in the Preferences dialog box.

The following display shows the command window and the toolbar in their default configuration.

![Figure 9.7 Default Configuration for Command Window and Toolbar](image)

Opening and Closing the Command Window and the Toolbar

The following table lists the steps that you can use to open and close the command window and toolbar.
Table 9.2  Steps for Opening and Closing the Command Window and the Toolbar

<table>
<thead>
<tr>
<th>Window</th>
<th>How to Open</th>
<th>How to Close</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command Window and Toolbar</td>
<td>To open both windows, complete any of the following steps:</td>
<td>To close these windows, complete any of the following steps:</td>
</tr>
<tr>
<td></td>
<td>▪ Issue the COMMAND WINDOW command.</td>
<td>▪ Select Close from the Toolbox window menu.</td>
</tr>
<tr>
<td></td>
<td>▪ Issue the TOOLLOAD command. For more information, see “TOOLLOAD Command: UNIX” on page 268.</td>
<td>▪ Enter the TOOLCLOSE command as described in “TOOLCLOSE Command: UNIX” on page 266.</td>
</tr>
<tr>
<td></td>
<td>▪ Select Tools ⇒ Options ⇒ Toolbox.</td>
<td>▪ Select Tools ⇒ Options ⇒ Toolbox so that Toolbox is deselected.</td>
</tr>
<tr>
<td>Command Window</td>
<td>To open only the command window, deselect Combine Windows on the tab of the Preferences dialog box, and complete any of the following steps:</td>
<td>To close only the command window, complete the following steps:</td>

</tr>
<tr>
<td></td>
<td>▪ Select Display tools window on the Toolbox tab of the Preferences dialog box.</td>
<td>▪ Deselect Display tools window on the Toolbox tab of the Preferences dialog box.</td>
</tr>
<tr>
<td></td>
<td>▪ Issue the TOOLLOAD command. See “TOOLLOAD Command: UNIX” on page 268.</td>
<td>▪ Issue the TOOLCLOSE command as described in “TOOLCLOSE Command: UNIX” on page 266.</td>
</tr>
<tr>
<td></td>
<td>▪ Select Tools ⇒ Options ⇒ Toolbox.</td>
<td>▪ Select Tools ⇒ Options ⇒ Toolbox so that Toolbox is deselected.</td>
</tr>
</tbody>
</table>
Executing Commands

You can execute commands from either the command window or the toolbar. The following table gives more details about how to execute commands.

Table 9.3 Executing Commands in the Command Window and the Toolbar

<table>
<thead>
<tr>
<th>Location</th>
<th>Execution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command Window</td>
<td>To execute a command, complete the following steps:</td>
</tr>
<tr>
<td></td>
<td>1. Click in the command window.</td>
</tr>
<tr>
<td></td>
<td>2. Enter the command.</td>
</tr>
<tr>
<td></td>
<td>3. Press Enter or click the check mark.</td>
</tr>
<tr>
<td></td>
<td>The command is executed in the active SAS window. You can use the up and down arrow keys to scroll through previously entered commands, or you can select a previous command from the drop-down list. Use the left mouse button to select a command from the drop-down list. Use the right mouse button to select and execute a command from the list.</td>
</tr>
<tr>
<td>Toolbar</td>
<td>To execute a command, click a tool icon in the toolbar to execute the command or commands that are associated with that icon. If you place the cursor over an icon for the amount of time specified by the <code>SAS.toolBoxTipDelay</code> resource, a pop-up window displays text that describes the command for that icon.</td>
</tr>
</tbody>
</table>

Opening Files in UNIX Environments

Opening the Open Dialog Box

The Open dialog box enables you to select files from the host file system. To open this dialog box, select `File` ➔ `Open`. 
Description of the Open Dialog Box Options

The following table describes the options found in the Open dialog box.

Table 9.4 Options in the Open Dialog Box

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter directory, name or filter</td>
<td>is where you can enter the name of the directory, file, or file filter (file type) that you want to open. The directory shown in the Filter field is the currently selected directory. You can change this directory either by selecting a name from the Page of Directories list or by entering the new name directly into the field. The dialog box displays non-readable directories with a different icon. To display a list of all the files in a directory, enter the asterisk (*) wildcard in the Filter field or select All Files; * as the file type.</td>
</tr>
<tr>
<td>Page of Directories</td>
<td>contains the names of the directories specified in the Filter and Page fields.</td>
</tr>
<tr>
<td>Files</td>
<td>contains the files in the selected directory that match the filter specified.</td>
</tr>
</tbody>
</table>
Option | Description
--- | ---
Page | enables you to change the directories that are listed in the Page of Directories list. A new page is defined when the number of entries in the Page of Directories list exceeds twice the screen height. To change pages, use the right or left arrows next to the Page field.

File type | enables you to select the type or types of files to be shown in the Files list. You can display a list of possible file filters by selecting the down arrow next to the field. Click on a file filter to select it.

Ignore Case | specifies that both uppercase and lowercase names be included in the display. (If you select All Files; * as the filter, both uppercase and lowercase names are displayed if you select Ignore Case.)

Include hidden | includes or excludes hidden files and directories from the graphical display.

Specifying the Initial Filter and Directory Using SAS Resources

You can specify the initial filter in the File type field by assigning a value to the SAS.pattern resource. However, the Open dialog box retains its filter between invocations, so the SAS.pattern resource applies only to the first invocation of the Open dialog box. You can also use the SAS.directory resource to specify the directory that you want when you first invoke the Open dialog box.

For more information about specifying SAS resources, see “Overview of X Resources” on page 186.

Using Regular Expressions in Filenames

Everything that you enter into the Open dialog box is treated as a regular expression. When you are opening or saving a file and you want to use a regular expression special character as part of the filename, precede the character with a backslash (\). For example, to write to a file named $Jan, enter \$Jan as the filename.

For more information about regular expressions, see UNIX man page 5 for regexp:

man 5 regexp
What Is Your Working Directory?

The working directory is the operating system directory to which many SAS commands and actions apply. By default, SAS uses the current directory as the working directory when you begin your SAS session.

Changing Your Working Directory

You can change the working directory during your SAS session. You can use the Change Working Directory dialog box to select a new directory, or you can use the X command, the X statement, the CALL SYSTEM routine, or the %SYSEXEC macro statement to issue the change directory (cd) command. For information about the X command and statement, the CALL SYSTEM routine, and the %SYSEXEC macro statement, see “Executing Operating System Commands from Your SAS Session” on page 17.

The Change Working Directory Dialog Box

To open the Change Working Directory dialog box, issue the DLGCDIR command or select Tools ▸ Options ▸ Change Directory.
The Change Working Directory dialog box works exactly the same as the Open dialog box, except that you cannot select a file from the list. For an explanation of the options in the Change Working Directory dialog box, see "Description of the Open Dialog Box Options" on page 171.

Selecting (Marking) Text in UNIX Environments

Difference between Marking Character Strings and Blocks

When you select text in a SAS window, you can select character strings or blocks. Character strings include the text in successive columns of one or more rows, as shown in the following display. Blocks are rectangular blocks that include the same columns from successive rows, as shown in Figure 9.11 on page 175.
Figure 9.10  Program Editor Window with Strings That Are Marked

Figure 9.11  Program Editor Window with Blocks That Are Marked

Techniques for Selecting Text

Select Text with the Mouse

To select your text, complete the following steps:

1. Position the cursor at the beginning of the text that you want to mark.
2. Press and hold the left mouse button. If you want to select a block instead of a string, press and hold the Ctrl key before you press the left mouse button.
3. Drag the mouse pointer over the text that you want to mark.
Press and hold down the Alt key (or Extend Char key or Meta key, depending on your keyboard) while you release the mouse button. The marks that are generated by the mouse are called drag marks.

To extend an area of marked text, press and hold the Shift key, and use the left mouse button and the Alt key (and the Ctrl key, if you are marking a block) to mark the new ending position. To unmark the selected text, press the mouse button anywhere in the window.

Select Text with the MARK Command

You can issue the MARK command from the command line, or you can assign it to a function key. With the MARK command, you can select more than one area of text in the same window at the same time. For more information about the MARK command, see the online SAS Help and Documentation.

To select your text, complete the following steps:

1. Position the cursor at the beginning of the text that you want to mark.
2. Issue the MARK command. If you want to select a block instead of a string, add the BLOCK argument to the MARK command.
3. Move the cursor to the end of the text that you want to mark.
4. Issue the MARK command a second time.

To unmark the selected text, issue the UNMARK command.

Select Text By Using the Edit Menu

To select your text using the Edit menu, complete the following steps:

1. Position the cursor at the beginning of the text that you want to mark.
2. Select Edit $\Rightarrow$ Select.
3. Position the cursor at the end of the text that you want to mark.
4. Press the left mouse button.

To unmark the selected text, select Edit $\Rightarrow$ Deselect.
Copying or Cutting and Pasting Selected Text in UNIX Environments

Techniques for Copying or Cutting and Pasting Selected Text

After you have marked text, you can copy or cut the text and paste it in another location.

- To copy text, select the Copy icon from the ToolBox, issue the STORE or WCOPY command, or select **Edit ➤ Copy**.
- To cut text, select the Cut icon from the ToolBox, issue the CUT or WCUT command, or select **Edit ➤ Cut**.
- To paste the cut or copied text, select the Paste icon from the ToolBox, issue the PASTE or WPASTE command, or select **Edit ➤ Paste**.

For more information about the CUT, PASTE, and STORE commands, see online SAS Help and Documentation.

How SAS Uses the Automatic Paste Buffer

When you end a drag mark by releasing the mouse button without holding down the Alt key, SAS performs an end-of-mark action that might automatically generate a STORE command to save the contents of the mark into a SAS paste buffer. If the STORE command is generated automatically, you do not have to explicitly copy the text before you paste it.

Disabling the Automatic Paste Buffer

You can disable the automatic paste buffer in the following ways:

- Set the `SAS.markPasteBuffer` resource.
- Deselect **Automatically store selection** on the Editing tab in the Preferences dialog box: **Tools ➤ Options ➤ Preferences**.

For more information, see “Customizing Cut and Paste in UNIX Environments” on page 229.
Copying and Pasting Text between SAS and Other X Clients

You can cut or copy and paste text between X clients if you associate the default SAS paste buffer with a paste buffer specific to X. For example, if you associate the default SAS paste buffer with the paste buffer, you can copy and paste text between xterm windows and SAS windowing environment. To associate the SAS buffer with an X buffer, specify the `SAS.defaultPasteBuffer` resource:

```
SAS.defaultPasteBuffer:  XTERM
```

For more information about using paste buffers, see “Customizing Cut and Paste in UNIX Environments” on page 229.

Using Drag and Drop in UNIX Environments

Difference between Default and Non-Default Drag and Drop

The SAS windowing environment on UNIX offers two types of drag and drop: default and non-default. Default drag and drop enables you to move text from one place to another. Non-default drag and drop enables you to choose whether to move or copy the text, submit the text if you are dragging SAS code, or cancel the drag and drop operation. With default drag and drop, you can drag text between SAS windows in different SAS sessions and between SAS windows and other Motif applications that support drag and drop. Non-default drag and drop is available only between windows in the same SAS session.

Limitations of Drag and Drop in UNIX

Under UNIX, you cannot drag and drop files or RTF (Rich Text Format) text.

How to Drag and Drop Text

To drag and drop text, first mark the text in one of the ways described in “Selecting (Marking) Text in UNIX Environments” on page 174. To use default drag and drop, use the middle mouse button to drag the text where you want it. To use non-default drag and drop, press and hold the Alt (or EXTEND CHAR) key before you release the mouse button.
Searching for and Replacing Text Strings in UNIX Environments

What Are the Find and Replace Dialog Boxes?

The Find and Replace dialog boxes enable you to search for and replace strings in SAS text editor windows such as the Program Editor, the SCL editor, or NOTEPAD.

Opening the Find Dialog Box

To search for a string, open the Find dialog box by issuing the DLGFIND command or by selecting Edit ➔ Find.

Description of the Find Dialog Box Options

The Find dialog box works like the Replace dialog box, except it does not have the Replace field or the Replace and Replace All buttons.

For a description of the options in the Find dialog box, see “Description of the Replace Dialog Box Options” on page 180.

Opening the Replace Dialog Box

To replace one text string with another, open the Replace dialog box by issuing the DLGREPLACE command or by selecting Edit ➔ Replace.

Figure 9.12 Replace Dialog Box
Description of the Replace Dialog Box Options

To find a character string, enter the string in the **Find** field, and click **Find**. To change a character string, enter the string in the **Find** field, enter its replacement in the **Replace** field, and click **Replace**. To change every occurrence of the string to its replacement string, click **Replace All**.

You can customize your find or replace operation using the following buttons:

**Match Case**
- tells the search to match the uppercase and lowercase characters exactly as you entered them.

**Match Word**
- searches for the specified string delimited by space, end-of-line, or end-of-file characters.

**Previous**
- searches from the current cursor position toward the beginning of the file.

**Next**
- searches from the current cursor position toward the end of the file.

Sending Mail from within Your SAS Session in UNIX Environments

Default Email Protocol in SAS

By default, SAS uses SMTP (Simple Mail Transfer Protocol) to send email from within your SAS session. You can use the EMAILSYS system option to specify which script or protocol you want to use for sending electronic mail. For more information, see "EMAILSYS System Option: UNIX" on page 395.

For more information about the SMTP email interface, see *SAS Language Reference: Concepts*.

What Is the Send Mail Dialog Box?

The Send Mail dialog box enables you to send email without leaving your current SAS session. To invoke the dialog box, issue the DLGSMAIL command or select **File ➤ Send Mail**.
Sending Email By Using the Send Mail Dialog Box

To send email, complete the following steps as needed:

1. Enter the IDs of the email recipients in the **To**, **Cc**, and **Bcc** fields. Separate multiple addresses with either spaces or commas.

2. Edit the entry in the **Subject** field as needed.

3. Enter the name of the file that you want to send in the **Attach** field. Separate multiple filenames with spaces. You can also use **Browse** to select a file.

   **Note:** Some external scripts do not support sending email attachments.

4. Enter your message in the message area or edit the contents grabbed from the active SAS text window.

5. Click **Send**.

To cancel a message, click **Cancel**.
Sending the Contents of a Text Window

You can email the contents of an active SAS text window (such as the Program Editor or the Log) by using the Send mail dialog box. To open the Send mail dialog box, select File ⇒ Send Mail. SAS automatically copies the contents of the active SAS window and includes the text in the body of your email. You can change or add to the email message in the Send mail dialog box.

If you do not want to include the contents of the active SAS window in your message, select Edit ⇒ Clear All before invoking the Send mail dialog box.

Sending the Contents of a Non-Text Window

To send the contents of a non-text window (such as a graph generated by SAS/GRAPH or an image from your PROC REPORT output), select File ⇒ Send Mail from the active SAS window. SAS automatically copies the image data to a temporary file and enters that filename into the Attach field of the Send mail dialog box. To change the default file type for this temporary file, see “Changing the Default File Type” on page 182.

SAS copies only the portion of the image that is visible in the active window, along with the window frame and title. This behavior is similar to using the DLGSCRDUMP command. For more information, see “DLGSCRDUMP Command: UNIX” on page 257.

If you do not want to attach this image to your email, clear the contents of the Attach field.

Note: Some external scripts do not support sending email attachments.

Changing the Default File Type

You can change the default file type for the temporary file that SAS creates by using the Preferences dialog box. To open the Preferences dialog box, follow these steps:

1. Select Tools ⇒ Options ⇒ Preferences.
2. On the DMS tab in the Image type for Email attachments box, select one of the following file types:
   - Portable Network Graphics (.png)
   - Graphics Interchange Format (.gif)
   - Tagged Image File Format (.tif)
Configuring SAS for Host Editor Support in UNIX Environments

Requirements for Using a Host Editor

SAS supports the use of a host text editor with the Motif interface, so you can use an editor such as vi or Emacs with your SAS session. There is no host editor set as the default host editor, so you must specify one to use this feature. Host editor support requires the use of the motifxsassm client. For more information, see "The SAS Session Manager (motifxsassm) in UNIX" on page 161.

Invoking and Using Your Host Editor

How to Open and Use the Host Editor

To use your host text editor with SAS, complete the following steps:

1 Specify the command required to invoke your editor with the EDITCMD system option.
2 Invoke the editor as needed with the HOSTEDIT command.

The HOSTEDIT command passes data from a SAS window to the host editor. When you save data in the host editor, the data is copied back into the SAS window if the window can be written to.

After you return to the SAS text editor window, you can issue the UNDO command to undo all of the changes that you made with your host editor. You must issue the UNDO command a second time to return to the state of the window before the HOSTEDIT command was issued. If you issue the HOSTEDIT command in a read-only window, you can save your editing changes to an external file, but the SAS text editor window remains unchanged.

For more information, see "EDITCMD System Option: UNIX" on page 394 and "HOSTEDIT Command: UNIX" on page 262.

Example 1: Invoking SAS to Use xedit with the HOSTEDIT Command

An X-based editor, called xedit, is installed on some systems. If you want to use xedit with the HOSTEDIT command, you can invoke SAS with the following command:

```
sas -editcmd '/usr/local/bin/xedit'
```
Example 2: Invoking SAS to Use vi

The vi editor is a terminal-based editor that requires a terminal window. The xterm client's -e option runs a program when the xterm client is invoked. To use the EDITCMD option to display an xterm client in conjunction with vi, invoke SAS as follows:

```
sas -editcmd '/usr/bin/X11/xterm -e /usr/bin/vi'
```

Troubleshooting the Transfer of Text Attributes

Text attributes, such as color and highlighting, are not transferred between a host editor window and a SAS text editor window. Issue the HEATTR ON command to display a dialog box that warns you if you are editing text with highlighting and color attributes that will be removed by the host editor. This dialog box prompts you to continue or stop the HOSTEDIT command. Specify HEATTR OFF to suppress this dialog box.

Getting Help in UNIX Environments

The Help menu is always available within your SAS session. Here are descriptions of the Help topics that are available from the Help menu:

Using This Window

provides help information that is relevant to the active window. You can access the same information by clicking the Help button or pressing the F1 key.

SAS Help and Documentation

provides tutorials and sample programs to help you learn how to use SAS, comprehensive documentation for all products installed at your site, and information about contacting SAS for additional support.

Note: If you set the block unrequested pop-up windows option in your browser’s Preferences dialog box, then the online SAS Help and Documentation might not be displayed.

Getting Started with SAS Software

opens a tutorial that helps you get started with SAS.

SAS on the Web

provides links to useful areas on the SAS website, including the customer support center, frequently asked questions, sending feedback to SAS, and the SAS home page. (See the SAS Technical Support site.)

About SAS 9

opens the About SAS 9 dialog box, which provides information about SAS software, your operating environment, and Motif.

Overview of Customizing SAS in X Environment

The SAS windowing environment supports the use of X-based graphical user interfaces (GUIs). In UNIX environments, SAS provides an X Window System interface that is based on the Motif style. For more information about SAS in the X environment, see “Description of SAS in the X Environment” on page 159.

You can customize your working environment by using X resources.

Overview of X Resources

Introduction to X Resources

X clients usually have characteristics that can be customized; these properties are known as X resources. Because SAS functions as an X client, many aspects of the appearance and behavior of the SAS windowing environment are controlled by X resources. For example, X resources can be used to define a font, a background color, or a window size. The resources for an application, such as SAS, are placed in a resource database.

SAS functions correctly without any modifications to the resource database. However, you might want to change the default behavior or appearance of the interface. There are several ways to specify your customizations. Some methods modify all SAS sessions displayed on a particular X server. Some methods affect all SAS sessions run on a particular host. Other methods affect only a single SAS session.
If you need more information about X Window System clients and X resources, see the documentation provided by your vendor.

Syntax for Specifying X Resources

A resource specification has the following format:

resource-string: value

The resource string usually contains two identifiers and a separator. The first identifier is the client or application name (SAS), the separator is a period (.) or asterisk (*) character, and the second identifier is the name of the specific resource. The value given can be a Boolean value (True or False), a number, or a character string, depending on the resource type.

The application name and resource name can both specify an instance value or a class value. A specification for a class applies to a larger scope than a single instance.

The following are sample resource specifications:

SAS.startSessionManager: True
SAS.maxWindowHeight: 100
SAS.awsResizePolicy: grow

See your X Window System documentation for more information about resource specifications.

Methods for Customizing X Resources

The following list describes the methods that you can use to customize X resources.

- Use the Font dialog box, the Preferences dialog box, or the Resource Helper to customize your SAS session. All of these tools write X resource definitions out to a location that SAS will read the next time you start a SAS session. For more information about these tools, see “Modifying X Resources through the Preferences Dialog Box” on page 189, “Setting X Resources with the Resource Helper” on page 195, and “Customizing Fonts in UNIX Environments” on page 217.

Note: The settings that you specify in the Preferences dialog box override any command line settings.

- Specify session-specific resources by using the -xrm option on the command line for each invocation of SAS. For example, the following command specifies that SAS will not display the Confirm dialog box when you exit your SAS session:

sas -xrm 'SAS.confirmSASExit: False'

You can specify the -xrm option as many times as needed. You must specify the -xrm option for each resource.
Note: If you normally invoke SAS with a shell script, you should protect the quotation marks from the shell with the backslash (\) character:

```bash
casscript -xrm \"SAS.confirmSASExit: False\"
```

Add resource definitions to a file in your home directory. If you place resources in a file that X Toolkit normally searches for when applications are invoked, these resources are loaded when you invoke SAS. For information about where the X Toolkit searches for resources, see the documentation for the X Window System.

You can also add resources to the resource database after SAS has initialized by running the `xrdb` utility. For example, the following command merges the definitions in the `MyResources` file into the resource database:

```bash
xrdb -merge myresources
```

Create a subdirectory for storing resource definitions. (This subdirectory is usually named `app-defaults`.) Set the `XUSERFILESEARCHPATH` environment variable to the pathname of this subdirectory. You can use `%N` to substitute an application class name for a file when specifying the `XUSERFILESEARCHPATH` environment variable. Specify the definition for this environment variable in the initialization file for your shell (for example, the `$HOME/.login`, `$HOME/.cshrc`, or `$HOME/.profile` files). This action ensures that the `XUSERFILESEARCHPATH` environment variable is defined for each shell that is started.

Create a file called `SAS` in the subdirectory identified by `XUSERFILESEARCHPATH`. Include your resource definitions in this file.

Note: Alternatively, you could set the `XAPPLRESDIR` environment variable to the pathname of the subdirectory that stores your resource definitions. The `XAPPLRESDIR` and `XUSERFILESEARCHPATH` environment variables use a slightly different syntax to specify the location of your resource definitions. The location specified by the `XUSERFILESEARCHPATH` environment variable takes precedence over the location specified by the `XAPPLRESDIR` variable. For more information, see the UNIX X man page.

If you want the customized resource definitions to be used for all users on a particular host, create a file called `SAS` to contain your customized resource definitions. Store this file in the system `app-defaults` directory.

For more information about X resources, see the X Window System documentation supplied by your vendor or other documentation about the X Window System.
Modifying X Resources through the Preferences Dialog Box

What Is the Preferences Dialog Box?

The Preferences dialog box enables you to control the settings of certain X resources. Changes that are made through the Preferences dialog box (with the exception of changes to resources on the General tab) become effective immediately. The settings are saved in the SasuserPrefs file in your Sasuser directory.

Note: The settings that you specify in the Preferences dialog box override any command line settings for the current session.

Opening the Preferences Dialog Box

You can open the Preferences dialog box by issuing the DLG PREF command or by selecting Tools ⇒ Options ⇒ Preferences.
Description of the Options in the Preferences Dialog Box

Modifying the General Settings

To modify the General settings, select the **General** tab in the Preferences dialog box, and then select from the items in the window:

**Start Session manager**

specifies whether you want the SAS Session Manager to be started automatically when you start your SAS session. If you want to use your host editor in your SAS session, the SAS Session Manager must be running. The SAS Session Manager enables you to interrupt or terminate your SAS session and minimize and restore all of the windows in a SAS session. See “The SAS Session Manager (motifxsassm) in UNIX” on page 161 and “Configuring SAS for Host Editor Support in UNIX Environments” on page 183 for more information. Clicking the **Start Session manager** box sets the `SAS.startSessionManager` resource.

**Startup Logo**

specifies whether you want SAS to display an XPM file while your SAS session is being initialized and, if so, which file.

If you select **Use Default Logo**, SAS uses the default file for your site. If you select **No Logo**, then no file is displayed. If you select **Use Custom Logo**, then...
you can either enter the XPM filename directly in the text field or click Select to open the File Selection dialog box. Selecting this box sets the $SAS.startupLogo resource.

**Use application workspace**

confines all windows displayed by an application to a single application workspace. Selecting this box sets the $SAS.noAWS resource. You must exit and reopen the windows for changes to this resource to take effect.

---

**Note:** In the UNIX operating environment, the application workspace (AWS) is turned on by default. If you are using the EFI window, and you want the window to remember its exact position and size, then you must turn off the AWS. To do this, select Tools ➜ Options ➜ Preferences, and deselect Use application workspace. Be sure to return the AWS to its default setting when your work in the EFI window is completed.

---

**AWS Resize Policy**

controls the policy for resizing AWS windows as interior windows are added and removed. (For more information, see “Workspace and Gravity in a SAS Session” on page 160 and “Window Types” on page 160.)

**Grow**
The AWS window attempts to grow anytime an interior window is grown or moved (to make all of its interior windows visible). It does not shrink to remove unused areas.

**Fixed**
The AWS window attempts to size itself to the size of the first interior window and does not attempt any further size changes.

Selecting this box sets the $SAS.awsResizePolicy resource.

---

**Modifying the DMS Settings**

To modify the DMS settings, select the DMS tab in the Preferences dialog box, and then select from the items in the window:

**Use menu access keys**

activates menu mnemonics. When mnemonics are turned on, you can select menu items by entering the single, underlined letter in the item. Selecting this box sets the $SAS.usePmenuMnemonics resource.

**Confirm exit**
displays the Exit dialog box when you exit your SAS session. Selecting this box sets the $SAS.confirmSASExit resource.

**Save Settings on Exit**
tells SAS to issue the WSAVE ALL command when you exit your SAS session. This command saves the global settings, such as window color and window position, that are in effect for all windows that are currently open. These settings are saved in your Sasuser.Profile catalog. Selecting this box sets the $SAS.wsaveAllExit resource.

---

**Note:** For the WSAVE command to work, your window manager must support explicit window placement. See the documentation for your window manager to determine how to configure your window manager. For example, if you are
running Exceed, open the Screen Definition Settings dialog box and deselect Cascade Windows.

Backup Documents enables you to specify whether you want SAS to automatically save (at the interval specified by the `SAS.autoSaveInterval` resource) the documents that you currently have open. Selecting this box sets the `SAS.autoSaveOn` resource.

Image type for Email attachments specifies the default file type for the temporary file that SAS creates when sending the contents of a non-text window via email. Examples of non-text windows include a graph generated by SAS/GRAPH or an image from your PROC REPORT output. For more information, see “Sending the Contents of a Non-Text Window” on page 182.

Modifying the Editing Settings

To modify the Editing settings, select the Editing tab in the Preferences dialog box, and then select from the items in the window:

**Default paste buffer** defines an alias for the default SAS buffer. The following list describes the paste buffer alias names and the X buffer with which each name is associated.

- **XPRIMARY** X primary selection (PRIMARY)
- **XSCNDARY** X secondary selection (SECONDARY)
- **XCLIPBRD** X clipboard (CLIPBOARD)
- **XTERM** exchange protocol used by the xterm client
- **XCUtn** X cut buffer where n is between 0 and 7, inclusive

Selecting this box sets the `SAS.defaultPasteBuffer` resource. See “Controlling Drop-down Menus in UNIX Environments” on page 229 for more information about cut-and-paste buffers.

**Automatically store selection** generates a STORE command every time you mark a region of text with the mouse. Selecting this box sets the `SAS.markPasteBuffer` resource.

**Cursor** controls the editing mode in SAS text editor windows. Selecting the Insert and Overtype boxes sets the `SAS.insertModeOn` resource to True and False, respectively.

Modifying the Results Settings

To modify the results settings, click the Results tab in the Preferences dialog box. The items on the Results tab affect output that is produced through ODS. (For a complete description of ODS, see the SAS Output Delivery System: User’s Guide.) Select from the items in this dialog box:
Create Listing
opens the ODS LISTING destination, which produces monospace output. Selecting this box is equivalent to entering the ODS LISTING SELECT ALL statement.

Create HTML
opens the ODS HTML destination, which produces output that is formatted in HTML. HTML is the default output type.

Folder
specifies a destination directory for HTML files. Specifying a directory in this field is equivalent to specifying a directory with the PATH option in the ODS HTML statement.

Use WORK Folder
tells ODS to send all HTML files to your Work directory. Selecting this box is equivalent to specifying the pathname of your Work directory with the PATH option in the ODS HTML statement.

Style
specifies the style template to use for HTML output. The style template controls such aspects as color, font name, and font size. Specifying a style in this field is equivalent to specifying a style with the STYLE option in the ODS HTML statement. You can specify any style that is defined in the ODS\PREFERENCES\STYLES key in the SAS registry. You can open the SAS registry by issuing the REGEDIT command, or by selecting Solutions ⇒ Accessories ⇒ Registry Editor.

The default style is HTMLBlue.

View results as they are generated
tells SAS to automatically display results when they are generated. If you select this box, make sure that Password protect HTML file browsing is deselected.

Password protect HTML file browsing
tells SAS to prompt you for your password before sending HTML files to your browser. If you select this box, make sure that View results as they are generated is deselected. Selecting this box sets the SAS.htmlUsePassword resource.

Use ODS Graphics
enables you to automatically generate graphs when running procedures that support ODS graphics. Use ODS Graphics is turned on by default.

Modifying the SAS ToolBox Settings
The items on the ToolBox tab of the Preferences dialog box affect both the ToolBox and the command window. To modify these settings, select the ToolBox tab in the Preferences dialog box:

Display tools window
determines whether to display the default toolbox. Selecting this check box sets the SAS.defaultToolBox resource.

Display command window
determines whether to display the command window. Selecting this check box sets the SAS.defaultCommandWindow resource.

Auto Complete Commands
specifies whether SAS automatically fills in the remaining characters of a command as you enter a command in the command window. SAS completes the
command with a command that you have previously entered that begins with the same characters. If both this box and Save Commands are selected, then SAS can automatically fill in commands that were entered in previous sessions. Selecting this check box sets the SAS.autoComplete resource.

**Save Commands**
specifies whether SAS saves the commands that you enter in the command window and how many commands are saved. You can specify a number from 0 to 50. If you specify 0, no commands are saved. If you specify 1 or more, that number of commands is saved in the file commands.hist in your Sasuser directory. If this box is selected, then SAS automatically fills in (see Auto Complete Commands) commands that were entered in previous sessions. Selecting this field sets the SAS.commandsSaved resource.

**Combine windows**
combines the ToolBox and command window into one window. The ToolBox and command window are combined by default. Selecting this check box sets the SAS.useCommandToolBoxCombo resource.

**Use arrow decorations**
adds arrows to both ends of the combined ToolBox and command window. Selecting this check box sets the SAS.useShowHideDecorations resource.

**Always on top**
keeps the ToolBox or the combined ToolBox and command window on top of the window stack. This check box is selected by default, which might cause problems with window managers and other applications that want to be on top of the window stack. If you have such a situation, turn off this feature. Selecting this check box sets the SAS.toolBoxAlwaysOnTop resource.

**Toolbox Persistent**
specifies whether the ToolBox that is associated with the Program Editor window stays open when you close the Program Editor. By default, the Program Editor ToolBox stays open whenever you close the Program Editor window. If you deselect this box, then the ToolBox closes if you close the Program Editor. Selecting this check box sets the SAS.isToolBoxPersistent resource.

The items in the Tools area affect the individual tools in the ToolBox.

**Use large tools**
controls whether tool icons are displayed as 24x24 or 48x48 pixels. The default is 24x24. Selecting this check box sets the SAS.useLargeToolBox resource.

**Use tip text**
specifies whether the ToolTip text is displayed when you position your cursor over a tool in the toolbox. Some window managers might place the toolbox tip behind the toolbox. If the toolbox tip is placed behind the toolbox in your environment, deselect this box. Selecting this check box sets the SAS.useToolBoxTips resource.

**delay**
controls the delay in milliseconds before popping up the toolbox tip. Selecting this check box sets the SAS.toolBoxTipDelay resource. You can enter a value directly into the field or use the arrows to the right of the field to change the value.
Setting X Resources with the Resource Helper

Introduction to the Resource Helper

With Resource Helper, you can customize the key definitions and the colors of the SAS interactive interface. Resource Helper creates SAS resource definitions and stores them in a location where the Resource Manager can find them. See “How the Resource Helper Searches for X Resources” on page 199 for a list of the locations that Resource Helper searches for resource definitions. Resource settings that are saved with Resource Helper will take effect the next time you start a SAS session.

You can start Resource Helper from within a SAS session or from your shell prompt.

How to Start the Resource Helper

Start the Resource Helper from a SAS Session

Start the SAS Resource Helper from a SAS window by entering the following command on the command line in the command window:

reshelper

Start the Resource Helper from a Shell Prompt

Resource Helper is installed in the /utilities/bin subdirectory in the directory where SAS is installed ($SASROOT). The name of the executable module is reshelper. For example, if SAS is installed in /usr/local/sas94, you start Resource Helper by entering the following command:

/usr/local/sas94/utilities/bin/reshelper &
Defining Keys with the Resource Helper

How to Define a Key

To define a key, follow these steps:

1. Start the Resource Helper (see “How to Start the Resource Helper” on page 195) and select the Keys icon.

![Keys Window for Resource Helper](image)

Key definitions are divided into several Action Categories:

- Move By Cursor
- Move By Field
- Edit
- Miscellaneous
- All Actions

2. Select Click here and press the keys you want to define.

3. Press the key or combination of keys that you want to assign an action to. For example, press F12. If a default SAS translation has already been assigned to the key combination, Resource Helper displays the default translation.

4. Select the action category menu button to open a list of action categories. Select the action category that you want. For example, if you want to define a key to delete the current field, select Edit as your Action Category. Resource Helper displays a list of actions in that category.

5. Select an action from the list (for example, Delete current field). Resource Helper can assign only one action to a translation. If the action that you select requires an argument (such as `sas-action-routine`), Resource Helper prompts you for the argument.

   Resource Helper displays the key combination and its new definition:

```
None<Key>F12: sas-delete()
```
Note: If you select the `sas-action-routine` `sas-function-key` action routine, then the key definition is automatically displayed in the Keys window. If you choose another action routine and if you want the definition to appear in the Keys window, you need to define a window label for the key. For information about defining labels in the Keys window, see “Syntax of the SAS.keysWindowLabels Resource” on page 212.

6 Select the right arrow to add this key translation to the list of User-Defined Keys.

7 Click OK to exit the Keys window after you have finished defining key translations.

8 To save your translations permanently, from the Resource Helper drop-down menus, select File ➤ Save Resources.

To modify a key definition that is already in the User-Defined Keys list, select the definition, select the left arrow to remove the definition from the list, and edit the definition.

To delete a definition from User-Defined Keys, select it and click Delete.

Clear clears the key definition edit window.

Default Defined Keys displays the default key definitions for your system.

Troubleshooting Incorrect Key Definitions

In most cases, using Resource Helper is much easier and faster than defining the resources yourself. However, the X Window System searches for resources in several places, so it is possible for Resource Helper to pick up the wrong key symbol for the key that you are trying to define. If you get unexpected results while using Resource Helper, you might need to define your key resources yourself. For more information, see “Defining Key Translations” on page 209.

Modifying the Color of a SAS Window Using the Resource Helper

How to Use the Color Window

You can modify the color of part of a SAS window as follows:

1 Start Resource Helper and select the Colors icon.
2 Select a category from the Category area.

3 Click a color or attribute in the Colors and Attributes window, or double-click a color to open the Customize Colors area, shown in the following display.

You can also change the attributes of some categories of SAS windows. The attributes options are HIGHLIGHT, UNDERLINE, or REVERSE.

You can customize a color by doing the following:
- selecting a new **Alias**
- moving the **Red**, **Blue**, or **Green** sliders
- selecting **Grab** and clicking a color anywhere on your screen

4 Click **OK** to exit the Customize Colors window after you have finished defining your color settings.

The result is displayed in the **Sample Window**. The hexadecimal value of the color is displayed at the bottom of the window.

Example: Change the Color of a SAS Window

The following example shows how to change the color of a SAS window.

1 Double-click **Red** in the Customize Colors window.
   
   The **From:** display shows the red currently used by the SAS windowing environment.

2 Click **Aquamarine** under **Aliases** and observe the change in the **To:** display.

3 Move the **Red**, **Green**, and **Blue** sliders with your mouse and note the changes in the color of the **To:** display.

4 Click **Apply** and note the difference in the color displayed as **Red** in the Colors area.

5 Click **OK** to save your changes.

Return to the Default Settings

Click **Defaults** to restore your color settings to their default values.

Permanently Save Your Color Settings

To save your color settings permanently, from the **Resource Helper** drop-down menus, select **File ➩ Save Resources**.

---

**How the Resource Helper Searches for X Resources**

The following list describes the locations where the Resource Helper searches for resource definitions and the order in which it searches these locations.

1 Resource Helper loads the resources in the file pointed to by the **XENVIRONMENT** environment variable. If XENVIRONMENT is not set, Resource Helper loads the resources in the **~/.Xdefaults-hostname** file, where **hostname** is the name of the server on which Resource Helper is running.

2 Resource Helper loads the resources defined in the **RESOURCE_MANAGER** property. If the **RESOURCE_MANAGER** property is the first location in which Resource Helper finds resources, the **RESOURCE_MANAGER** property overrides any resources that you generate with Resource Helper.
To determine whether any resources have been defined in your RESOURCE_MANAGER property, issue the following command:

```
xrdb -q | more
```

If no listing is returned, the RESOURCE_MANAGER property does not exist. In this case, Resource Helper loads the resources defined in the ~/.Xdefaults file.

3 Resource Helper loads the resources in the file pointed to by the XUSERFILESEARCHPATH environment variable.

You can use `${N}` to substitute an application class name for a file when specifying the XUSERFILESEARCHPATH environment variable. For example, to point to `/usr/local/resources` as the location of all the resources for any application, issue the following command in the Bourne or Korn shells:

```
export XUSERFILESEARCHPATH=\n/usr/local/resources/%N
```

In the C shell, the command is the following:

```
setenv XUSERFILESEARCHPATH /usr/local/resources/%N
```

As a result, when SAS is invoked, the file pointed to by XUSERFILESEARCHPATH is the following:

```
/usr/local/resources/SAS
```

SAS is the application class name for SAS.

4 Resource Helper loads the resources in the file specified by the XAPPLRESDIR environment variable. The application’s class name is appended to the XAPPLRESDIR environment variable and the resulting string is used to search for resources. For example, you can issue the following command in the Bourne or Korn shells:

```
export XAPPLRESDIR=/usr/local/app-defaults
```

If you do this, then at the next invocation of SAS, the application’s class name is appended to the path:

```
/usr/local/app-defaults/SAS
```

In the C shell, the command is the following:

```
setenv XAPPLRESDIR /usr/local/app-defaults
```

5 Resource Helper loads the resources in the file named ~/.SAS.

6 Resource Helper loads the resources in the file or substitution specified by the XFILESEARCHPATH environment variable.

```
Note: To determine whether an environment variable has been set, you can issue the following command:
```
```
eenv|grep <environment_variable>
```
```
```
7 Resource Helper loads the resources defined in the /usr/lib/X11/app-defaults file. Resource Helper does not need to have Write access to this file. However, it must be able to read the file and add SAS resources to a resource file to which it has Write access. Resource Helper does not generate a warning message if the file is not present or if it cannot read the file.
Resource Helper loads the fallback resources that are defined in the SAS code. Except for the `/usr/lib/X11/app-defaults` file, Resource Helper tries to write the new resources to the same directory and file where it first found SAS resources. This location must be a file that has Write access and a directory that has Write access. If Resource Helper cannot write to the file, the SAS resources in that file remain in effect and any new or modified resources generated by Resource Helper do not take effect. If this situation happens, Resource Helper displays an error dialog box that contains the file or directory and suggests a way to fix the problem.

Customizing Toolboxes and Toolsets in UNIX Environments

Techniques for Customizing Toolboxes

You can customize toolboxes in the following ways:

- Through the Preferences dialog box. The Preferences dialog box enables you to customize the appearance and behavior of toolboxes. For information about using the Preferences dialog box, see “Modifying X Resources through the Preferences Dialog Box” on page 189 and “Modifying the SAS ToolBox Settings” on page 193.

- By specifying SAS resources in your resource file. For a description of the SAS resources that affect toolboxes, see “X Resources That Control Toolbox Behavior” on page 201.

- Through the Tool Editor. The Tool Editor enables you to customize the individual tools in a toolbox. For more information, see “Using the Tool Editor” on page 202.

X Resources That Control Toolbox Behavior

You can control the behavior of toolboxes with the following SAS resources:

**SAS.autoComplete:** True | False

specifies whether SAS automatically fills in the remaining characters of a command as you enter a command in the command window. SAS completes the command with a command that you have previously entered that begins with the same characters. The default value is True.

**SAS.commandsSaved:** number-of-commands-saved

specifies whether SAS saves the commands that you enter in the command window and how many commands are saved. You can specify a number from 0 to 50. If you specify 0, no commands are saved. If you specify 1 or more, that number of commands is saved in the file `commands.hist` in your Sasuser directory. If you specify 1 or more for this resource and `SAS.autoComplete` is True, then SAS can automatically fill in commands that were entered in previous sessions. The default value is 25.
SAS.defaultToolBox: True | False
controls opening the default toolbox when SAS is invoked. The default is True.

SAS.isToolBoxPersistent: True | False
controls whether the toolbox that is associated with the Program Editor stays open when you close the Program Editor. The default value is True.

SAS.toolBoxAlwaysOnTop: True | False
controls whether the toolbox is always on top of the window stack. The default value, True, might cause problems with window managers that are not Motif interface window managers or with applications that want to be on top of the window stack. If you have such a situation, set this resource to False.

SAS.toolBoxTipDelay: delay-in-milliseconds
sets the delay in milliseconds before displaying the toolbox tip. The default is 750.

SAS.useCommandToolBoxCombo: True | False
controls whether the command window and toolbox are joined or separated. The SAS.defaultToolBox and SAS.defaultCommandWindow resources control whether the toolbox and command window are displayed. If both are displayed, this resource controls whether they are joined or separated. The default value is True.

SAS.useLargeToolBox: True | False
controls whether tool icons in the toolbox are displayed as 24x24 pixels or 48x48 pixels. The default is False (24x24 pixels).

SAS.useShowHideDecorations: True | False
controls whether the combined command window and toolbox window has arrows at the left and right. You can use these arrows to hide or show portions of the window as they are needed. The default value is False.

SAS.useToolBoxTips: True | False
determines whether toolbox tip text is displayed. Some window managers might place the toolbox tip behind the toolbox. If the toolbox tip is placed behind the toolbox in your environment, set this resource to False. The default is True.

Using the Tool Editor

What Is a Toolset?
The Tool Editor enables you to create custom toolsets for your SAS applications. A toolset is a set of predefined tools that is associated with an application. Toolsets make it easier for individual users to customize their application toolboxes. If you create a toolset for an application, you can select Actions in the Tool Editor and choose the tools that you want to appear in the toolboxes. You do not have to define the icons, commands, tip text, and IDs for those tools.

For example, you can define a default toolbox for your application that includes tools for opening files, cutting, copying, and pasting text, and saving files. You can define a toolset that includes those tools and tools for opening the Preferences dialog box, opening the Replace dialog box, and entering the RECALL command. These additional tools do not appear in your toolboxes unless you add them to your toolboxes with the Tool Editor. For more information, see “Changing the Attributes of
Invoking the Tool Editor

You can change the appearance and contents of a toolbox using the Tool Editor. To invoke the Tool Editor, select Tools ⯈ Options ⯈ Edit Toolbox. Alternatively, you can issue the TOOLEDIT command as described in “TOOLEDIT Command: UNIX” on page 267.

The following display shows an example of a Tool Editor dialog box that was opened from the Tools menu in the Program Editor window:

*Figure 10.6 Tool Editor Dialog Box*

By default, the Tool Editor enables you to edit the current toolbox. To edit a different toolbox, click the Open button in the Tool Editor dialog box. Specify a library, catalog, and entry name for the toolbox that you want to edit. The following display shows the Open dialog box:

*Figure 10.7 The Open Dialog Box*
After You Invoke the Tool Editor

After you invoke the Tool Editor, the toolbox is displayed in preview mode. In preview mode, clicking a tool icon to select a tool makes that icon the current icon. Its associated commands are displayed in the Command field. Attributes in the Help Text, Tip Text, and ID fields might also be displayed, depending on whether this information was added when the tool was created or updated. For more information about the fields and buttons in the Tool Editor dialog box, click the Help button.

Changing the Appearance of the Entire Toolbox

The items in the ToolBox area of the Tool Editor affect the entire toolbox:

**Name**
- displays the catalog entry that you are editing. The default toolbox is named Sasuser.Profile.Dms.Toolbox.

**Max tools per row**
- specifies how the icons in the toolbox are arranged. The default value creates a horizontal toolbox. One tool per row creates a vertical toolbox.

Changing the Attributes of an Existing Tool

When you open the Tool Editor, the first tool in the toolset is selected, and the attributes for this tool appear in the Button area of the Tool Editor dialog box. If you click another icon in the toolset, the Tool Editor displays the attributes of that tool.

Alternatively, you can select a tool from the toolset that is displayed when you click the Actions button. When you click OK after you select a tool, the attributes in the Button area of the Tool Editor are updated to correspond to the new tool.

---

**Note:** Clicking the Actions button displays a toolset only if a toolset is associated with (has the same entry name as) the toolbox that you are editing. For more information, see “Saving Changes to the Toolbox or Toolset” on page 206.

---

When you have selected the tool that you want to change, you can then select an attribute field in the Tool Editor and enter the changes that you want to make.

To modify the attributes of a tool, follow these steps:

1. From the toolset, select the tool that you want to change.
2. In the Button area, select an attribute field associated with a button and change the text as appropriate:

   **Command**
   - specifies the command or commands that you want executed when you click the icon. You can use any windowing environment command that is available under UNIX. For information about commands that are valid in all operating environments, see SAS Help and Documentation. Separate commands with a semicolon (;). For example, you could create an icon to open the Change Working Directory dialog box by using the DLGCDIR command.
Help Text
is used for applications that are designed to be run under Windows. The Help text is displayed in the AWS status bar on Windows when a toolbox is ported to and loaded on those windows.

Tip Text
specifies the text that is displayed when you position the cursor over the icon.

ID
is useful if you are creating toolboxes for SAS/AF applications. The ID is the identifier of the corresponding menu item in the application. This number is the value assigned to the item in the ID option of the ITEM statement in PROC PMENU. If you specify an ID, then the application can set the state of the PMENU item to match the state of the tool in the toolbox. It can make the PMENU item active or inactive to match whether the tool in the toolbox is active or inactive. If you do not specify an ID, the ID defaults to 0.

3 Change the icon if necessary.

a Click the Icon button or double-click an icon in the preview toolbox. The Tool Editor opens the Select a pixmap dialog box, which displays the icons that are provided with SAS. These icons are divided into several categories such as SAS windows, data, analysis, numbers and symbols, files, folders, and reports, and so on. To change categories, select the arrow to the right of the Icon Category field and select a new category.

b Select the icon that you want to use, and then select OK.

The following display shows the Select a pixmap dialog box:

4 Save your changes as described in “Saving Changes to the Toolbox or Toolset” on page 206.

Adding Tools to the Toolbox
To add a tool to the toolbox, follow these steps:

1 Select the icon next to where you want to add the new tool.
2 Select Add before or Add after. The Tool Editor adds a new icon to the toolbox and clears the Button fields.

3 Enter the appropriate information in the Button fields as described in “Changing the Attributes of an Existing Tool” on page 204.

4 Change the attributes of the icon, if necessary, as described in “Changing the Attributes of an Existing Tool” on page 204.

5 Save your changes as described in “Saving Changes to the Toolbox or Toolset” on page 206.

Change the Order of the Tools in the Toolbox

To change the position of a tool in the toolbox, select the tool icon, and then click the left or right arrows to move the tool.

Deleting Tools from the Toolbox

To delete a tool from the toolbox, follow these steps:

1 Select the tool that you want to delete.

2 Click Delete.

3 Save your changes as described in “Saving Changes to the Toolbox or Toolset” on page 206.

Returning to the Default Settings

To return all tools in the current Toolbox to their default settings, click Defaults. The Tool Editor asks you to verify your request. Click Yes, No, or Cancel.

Saving Changes to the Toolbox or Toolset

You can save the changes to the catalog entry shown in the Name field or create a new toolbox with a different name.

If you are customizing a window- or application-specific toolbox or toolset for your own use, you should save the customized toolbox or toolset in your Sasuser.Profile catalog. Use the same entry name as the PMENU entry for the window or application. SAS searches for toolboxes and toolsets first in the Sasuser.Profile catalog, and then in the application catalog.

If you are a SAS/AF application developer or site administrator and you are editing a window- or application-specific toolbox that you want to be accessible to all users, you must save the TOOLBOX entry with the same library, catalog, and entry name as the PMENU entry for the window or application. To associate a toolset with a specific toolbox, save the TOOLSET entry with the same library, catalog, and entry name as the TOOLBOX entry. You must have Write permission to the appropriate location. For example, to store a customized toolbox for the graphics editor, the site administrator needs to store the toolbox in SASHELP.GI.GEDIT.TOOLBOX.

Clicking the Save button saves the toolbox information to the catalog entry shown in the Name field. Clicking the Save As button prompts you to enter a different library, catalog, and entry name. You can also choose to save the toolbox as a toolset. If
you save the toolbox as a toolset, the entry type is TOOLSET. Otherwise, the entry type is always TOOLBOX. (Saving a set of tools as a TOOLSET does not change your TOOLBOX entry.) For more information about toolsets, see “Customizing Toolboxes and Toolsets in UNIX Environments” on page 201 and “Create or Customize an Application- or Window-Specific Toolset” on page 208.

If you click the Close button or the Open button without first saving your changes, the Tool Editor prompts you to save the changes to the current toolbox or toolset before continuing.

After you save the toolbox or toolset, the Tool Editor remains open for additional editing. The Name field changes to the name of the new entry (if you entered a new entry).

Creating a New Toolbox

To create an entirely new toolbox, choose from the following methods:

- Edit an existing toolbox using the Tool Editor and then save the toolbox by clicking the Save as button as described in “Saving Changes to the Toolbox or Toolset” on page 206.

Create or Customize an Application- or Window-Specific Toolbox

If you are an application developer and want to create or edit an existing application toolbox, follow these steps:

1. Delete any existing TOOLBOX entry in your Sasuser.Profile for the window or application that you want to customize.
   
   Deleting the copy of the toolbox in your Sasuser.Profile enables you to pick up a copy of the toolbox that is supplied with SAS when you invoke the Tool Editor.

2. Create or edit the application toolbox as described in “Creating a New Toolbox” on page 207 or “Using the Tool Editor” on page 202.

3. Save the edited toolbox as described in “Saving Changes to the Toolbox or Toolset” on page 206.

4. Inform your users that you have changed the window or application toolbox.
   
   If users want to use the new toolbox, they must delete the corresponding TOOLBOX entry from their Sasuser.Profile. The new toolbox is then automatically loaded when the window or application is invoked. If a user does not delete the corresponding TOOLBOX entry from their Sasuser.Profile, that copy of the toolbox is loaded instead of the new toolbox.

The TOOLLOAD and TOOLCLOSE commands are most useful when you are developing SAS/AF applications. You can use the EXECCMDI routine with these commands to enable your application to open and close the toolbox and to give users of your applications access to several toolboxes during the course of their
work. For a description of the EXECCMDI routine, see SAS Component Language: Reference.

Create or Customize an Application- or Window-Specific Toolset

You define application- or window-specific toolsets in the same way that you create an application- or window-specific toolbox. There are only two differences:

- To create a new toolset, start by defining a toolbox as described in “Creating a New Toolbox” on page 207.
- After you have defined the toolbox, save it as a TOOLSET entry, not as a TOOLBOX entry.

Note: If you are an application developer, ensure that you delete any existing TOOLSET entry for your application as described in “Create or Customize an Application- or Window-Specific Toolbox” on page 207 before you modify your application's toolset.

Customizing Key Definitions in UNIX Environments

Techniques for Customizing Your Key Definitions

There are four ways to customize your key definitions:

- through the Keys window

  To open the Keys window, issue the KEYS command or select **Tools** ⇒ **Options** ⇒ **Keys**. If you change any key definitions through the Keys window for the primary SAS windowing environment windows, the definitions are stored in the Sasuser.Profile catalog in the entry DMKEYS.KEYS. Key definitions for other SAS windows are stored in catalog entries named BUILD.KEYS, FSEDIT.KEYS, and so on.

  See the online SAS Help and Documentation for more information about the KEYS command and the Keys window.

- with the KEYDEF command

  The KEYDEF command enables you to redefine individual function keys:

  ```bash
  keydef keyname <command|~text-string>
  ```

  For example, if you specify `keydef F8 dlgpref`, then the **F8** key opens the Preferences dialog box.
For more information about the KEYDEF command, see the Base SAS section in the online SAS Help and Documentation.

- through the Resource Helper (reshelper)

Resource Helper generates SAS resource specifications based on keys and functions that you select. You can use Resource Helper to change the function of any key that is listed in the Keys window. For more information about the Resource Helper, see “Setting X Resources with the Resource Helper” on page 195 and “Defining Keys with the Resource Helper” on page 196.

In most cases, Resource Helper is much easier and faster than defining the resources yourself. However, because the X Window System searches for resources in several places, it is possible for Resource Helper to pick up the wrong key symbol for the key that you are trying to define. Also, unless the action routine that you assign to your keys is the sas-function-key routine, Resource Helper does not provide a way to change the key labels in the Keys window. In both of these cases, you need to define your key resources yourself.

- by defining the SAS.keyboardTranslations and SAS.keysWindowLabels resources in your resources file as described in “Defining Key Translations” on page 209.

You can define most of the keys on your keyboard. However, a few keys have functions that are previously defined for them. For example, the mouse buttons are dedicated to the cursor and cut-and-paste operations and are not available for user customization.

---

**Defining Key Translations**

**What Is a Key Translation?**

Key customization for the X Window System consists of defining a key sequence and an action to be executed when that key sequence is typed on the keyboard. This customization is known as binding keys to actions; together they are referred to as a translation.

**What Is the SAS.keyboardTranslations Resource?**

The SAS.keyboardTranslations resource specifies the set of key bindings that SAS uses in all SAS windows. The default value for the SAS.keyboardTranslations resource is determined at run time based on the vendor identification string reported by the X server that you are using as the display. These defaults are listed in the files contained in $SASROOT/X11/resource_files. To modify the default bindings that are supplied by SAS, you must modify the SAS.keyboardTranslations resource.

---

**Note:** The X Toolkit Intrinsics translations that are specified in this resource apply to both the user area and the command line of all SAS windows that are affected by this resource. This resource does not affect windows that are controlled by Motif interface resources. These windows include the Command window, the Open or Import dialog boxes, and some other drop-down menu dialog boxes.
Steps for Creating a Key Definition

To create a key definition, follow these steps:

1. Determine the keysyms for the keys that you want to define.

   Keysyms are the symbols that are recognized by the X Window System for each key on a keyboard. For more information, see "Determining Keysyms" on page 210.

2. Modify or add the `SAS.keyboardTranslations` resource in your resource file to include the definitions of the keys that you want to define.

   Use a keyboard action routine to define which action you want the key to perform. The definition in the right column in the Keys window no longer controls the function of any keys that are defined with a keyboard action routine other than `sas-function-key`. The definitions of those keys in the Keys window become labels that have no effect. For more information, see "Syntax of the SAS.keyboardTranslations Resource" on page 211.

3. Modify or add the `SAS.keysWindowLabels` resource in your resource file.

   The `SAS.keysWindowLabels` resource specifies the set of valid labels that appear in the Keys window. Modify this resource only if you want to add new labels or modify existing labels in the left column in the Keys window.

   The `SAS.keysWindowLabels` resource defines only the mnemonics used in the Keys window. For a specific key to perform an action, you must specify a `SAS.keyboardTranslations` definition for the key. For more information, see "Syntax of the SAS.keysWindowLabels Resource" on page 212.

4. Start a SAS session and open the Keys window.

5. In the right column in the Keys window, enter a command name or other description of each key that you have defined.

For examples of key definitions, see "Examples: Defining Keys Using SAS Resources" on page 216.

Determining Keysyms

You can use the `xev` utility to determine the keysyms that are associated with the keys on your keyboard. The `xev` utility is distributed with most UNIX operating systems. If `xev` is not installed in your operating environment, contact your UNIX system administrator for information about other methods that are available in your operating environment. The `xev` utility writes a message for each X event that occurs. The `KeyPress` event specifies the keysym for each key that is pressed.

To define keys, follow these steps:

1. Start the `xev` utility on the X server for which you want to define keys.

   The `xev` client displays a small Event Tester window that lists the X events that occur. (The `xev` client generates a large amount of output, so you might want to save the output to a file for later review. You can issue the UNIX `script` command to save the output to a file.)

2. Give keyboard focus to the Event Tester window by clicking the mouse pointer on the window, if necessary.
Press the key that you want to define, and watch for the **KeyPress** event to be listed.

The listing contains a number of items that are separated by commas. One of the fields in the **KeyPress** event lists the keysym name that is associated with the key that was pressed.

For example, when the 0 key on the keypad of a Dell PC 105 keyboard is pressed, and the NumLock modifier is toggled on, it generates the following output:

```
KeyPress event, serial 32, synthetic NO,
window 0x1a00001, root 0x5d, subw 0x1a00002,
time 600120687, (37,41), root:(240,458),
state 0x10, keycode 90 (keysym 0xffb0, KP_0),
same_screen YES,
XLookupString gives 1 bytes: (30) "0"
XmbLookupString gives 1 bytes: (30) "0"
XFilterEvent returns: False
```

In this example, the keysym name is **KP_0**.

**Note:** SAS defines a set of virtual keysyms with the `SAS.defaultVirtualBindings` resource. Virtual keysyms all begin with `osf`, such as `osfPageDown`, `osfClear`, and `osfPrimaryPaste`. If you remap these virtual bindings instead of using the defaults supplied by SAS, you might get unexpected results. If you specify a key translation that does not work, you might be trying to redefine a key that is bound to a virtual keysym. In this case, you must specify the virtual keysym in the `SAS.keyboardTranslations` resource instead of the keysym that is displayed by the `xev` utility. To determine the virtual keysym that is bound to a key, you can start the Resource Helper, click **Keys**, and press the key or key combination that you want to define. Resource Helper displays the virtual keysym name. You can also refer to the key definition files in `/Xll/resource_files` in the directory where SAS is installed (`!SASROOT`) and to the UNIX man pages for VirtualBinding or xmbind.

---

### Syntax of the SAS.keyboardTranslations Resource

**Note:** Most SAS documentation uses angle brackets (<>\) to indicate optional syntax. However, in this topic, optional syntax is shown with square brackets ([]). The angle brackets that are shown in this topic are part of the syntax and should be entered exactly as shown.

Here is the syntax of the `SAS.keyboardTranslations` resource:

```
SAS.keyboardTranslations: #override \\
[modifier] <Key>keysym : action-routine \\
[modifier] <Key>keysym : action-routine
```

`#override` indicates that this definition should override any existing bindings for the specific keys that you define without affecting any other keys. If you omit the `#override` directive, the new bindings replace all of the default bindings, and none of the other keys on the keyboard will be available.
Note: For information about the `#augment` and `#replace` directives, see the documentation for the X Window System.

**modifier**

can be one of the following:

- Alt
- Ctrl
- Meta
- Shift
- Lock
- Mod1
- Mod2
- Mod3
- Mod4
- Mod5
- None
- blank space

The list of valid modifiers varies depending on your keyboard. To display a list of valid modifiers for your keyboard, enter the `xmodmap` UNIX command. For more information, see the UNIX man page for `xmodmap`.

**<Key>**

is required. It signals the beginning of the keysym.

**keysym**

is the key symbol recognized by X for the key that you are defining. For more information, see “Determining Keysyms” on page 210.

**action-routine**

is what you want the key to do. You can specify any action routine described in “SAS Keyboard Action Names” on page 213.

\n
enables the X translation manager to determine where one translation sequence ends and the next one begins. Do not enter `\n` after the end of the last translation.

\n
prevents the newline character at the end of the line from being interpreted as part of the definition. Using this character is a stylistic convention that allows each translation to be listed on a separate line. Do not enter a backslash after the end of the last translation.

Note: SAS does not prevent you from specifying invalid keys in the `SAS.keyboardTranslations` resource. In some cases, invalid keys produce warnings in the shell window.

Syntax of the SAS.keysWindowLabels Resource
Note: The square brackets ([ ]) in the following syntax indicate that (InternalKeyName) is optional.

Here is the syntax of the SAS.keysWindowLabels resource:

SAS.keyWindowLabels:
KeyWindowLabel [(InternalKeyName)] \n\nKeyWindowLabel [(InternalKeyName)]

KeyWindowLabel
is the label (1 to 8 characters) that you want to appear in the Keys window.

InternalKeyName
is the character string that is passed to the sas-function-key action routine in the corresponding SAS.keyboardTranslations key binding. (InternalKeyName) is used by SAS to correlate Keys window entries to key definitions in the KEYS modules loaded from SAS catalogs or defined in the SAS Keys window. If the InternalKeyName is not specified, SAS uses the KeyWindowLabel as the InternalKeyName.

\n and \n
serves the same purpose as in the SAS.keyboardTranslations resource. For more information, see “Syntax of the SAS.keyboardTranslations Resource” on page 211.

SAS Keyboard Action Names

Note: Most SAS documentation uses angle brackets (<>) to indicate optional syntax. However, in this topic optional syntax is shown with square brackets ([ ]). The angle brackets that are shown in this topic are part of the syntax and should be entered exactly as shown.

SAS declares a set of keyboard actions during X initialization. You can think of these keyboard actions as simple functions. When the actions are executed, they act on the window that currently has keyboard input focus.

The following list of keyboard actions represents action routines registered by the Motif interface for use with X Toolkit keyboard event translations.

sas-cursor-down()
  moves the cursor down one line in the SAS window. The cursor does not wrap when it reaches the bottom of the SAS window interior.

sas-cursor-left()
  moves the cursor left one character in the SAS window. The cursor does not wrap when it reaches the left side of the SAS window interior.

sas-cursor-right()
  moves the cursor right one character in the SAS window. The cursor does not wrap when it reaches the right side of the SAS window interior.

sas-cursor-up()
  moves the cursor up one line in the SAS window. The cursor does not wrap when it reaches the top of the SAS window interior.

sas-delete()
  deletes all text in the current field.
sas-delete-begin() deletes text from the current cursor position to the beginning of the current text field.

sas-delete-char() deletes the character under the text cursor and leaves the cursor in place.

sas-delete-end() deletes text from the current cursor position to the end of the current text field.

sas-delete-prev-chr() deletes the character to the left of the text cursor and moves the cursor back one space.

sas-delete-prev-word() deletes text to the start of the previous word from the current cursor position. If the cursor is in the interior of a word when the action is invoked, the text from the cursor position to the start of the word is deleted.

sas-delete-word() deletes text from the current cursor position to the end of the current or next word.

sas-do-command() accepts one or more text string parameters that are interpreted as SAS commands to be executed when the action is invoked. The action might be invoked with multiple parameters. The parameters are concatenated with semicolon delimiters supplied by the sas-do-command action between the parameters. The assembled SAS command string is then submitted for execution. For example, the following translation syntax can be used to define a HOME, SUBMIT key sequence for all SAS windowing environment windows:

<Key>KP_F3: sas-do-command(HOME;SUBMIT)

sas-function-key("InternalKeyName") invokes the SAS commands associated with the function key identified by the InternalKeyName label. InternalKeyName is the character string (1 to 8 characters long) that is passed to the keysWindowLabels resource. Enclose InternalKeyName in quotation marks. For a description of internal key names, see "Defining Key Translations" on page 209.

sas-home-cursor() is the equivalent of the HOME command. It is provided for convenience so that the HOME action could be defined for all SAS windowing environment windows.

sas-insert-char("InsertionString") inserts or overwrites the character entered into the input field under the text cursor. Insert or overwrite behavior is determined by the sas-toggle-insert action, which has a mode that is reflected by the text cursor style displayed; the block cursor indicates overwrite mode, and the underline cursor indicates Insert mode. Normally, sas-insert-char translates the XKeyEvent into the appropriate character and inserts it at the SAS text cursor location. If you specify the parameter, the text string represented by this parameter is inserted at the SAS text cursor location. White space in the string is interpreted by the X Toolkit as a parameter delimiter unless you enclose the string in double quotation marks. See your X Window System documentation for information about embedding quotation marks in the string parameter. To include an escaped quotation mark, use the following syntax:

Shift<Key>KP_1: sas-insert-char("One"1"")

This syntax produces the text string One1" at the SAS text cursor location.
sas-kp-application()
sets the workstation's numeric keypad to allow function key translations to be
reinstated. This action works only for those keypad keys that are bound to
sas-function-key() actions. Keypad bindings to other actions are not affected
by this translation.

sas-kp-numeric()
sets the workstation's keypad to generate numeric characters instead of its
previous function key assignment. This action works only for keypad keys that
are bound to sas-function-key() actions. Keypad bindings to other actions are
not affected by this translation.

sas-move-begin()
moves the cursor to the beginning of the current text field.

sas-move-end()
moves the cursor to the end of the current text field.

sas-new-line()
generates an end-of-line event when invoked. This action is context sensitive. If
the action is entered on the SAS command line, the text entered is submitted for
execution. If invoked in the SAS application client area, the action depends on
the attributes of the text area under the text cursor. In simplest terms, this action
is the general line terminator for an input field.

sas-next-field()
advances the SAS application to the next field in the SAS window client area.

sas-next-word()
shifts the text cursor forward to the beginning of the next word in the current text
field. If sas-next-word does not find the beginning of a word in the current text
field, it advances to the next SAS application field. If you are typing in the SAS
command line area of the window, the cursor does not wrap into the SAS
window client area.

sas-page-down()
scrolls the current window contents forward by one page.

sas-page-end()
moves the text cursor to the end of the current page.

sas-page-top()
moves the text cursor to the top of the current page.

sas-page-up()
scrolls the window contents backward by one page.

sas-prev-field()
returns the SAS application to the previous field in the SAS window client area.

sas-prev-word()
shifts the text cursor backward to the beginning of the previous word in the
current text field. If sas-prev-word does not find the beginning of a previous
word in the current text field, it returns to the end of the previous SAS application
field. If you are typing in the SAS command line area of the window, the cursor
does not wrap into the SAS window client area.

sas-to-bottom()
moves the text cursor to the absolute bottom of the window's text range.

sas-to-top()
moves the text cursor to the absolute top of the window's text range.
sas-toggle-insert() switches the associated window line-editing behavior between insert and overstrike modes. This switching applies only to the SAS command line and the SAS window client area. The current mode is indicated by the cursor style in use. The block cursor indicates overstrike mode, and the underline cursor indicates Insert mode.

sas-xattr-key(<KeyType>[,<KeyParam>]) processes SAS extended attribute keys. The KeyType parameter must be one of the following values: XACOLOR, XAATTR, XACLEAR. For KeyType XACOLOR, the 12 DMS color names are valid parameters; for KeyType XAATTR, the valid values are HIGHLIGHT, REVERSE, BLINK, and UNDERLINE; for XACLEAR, no parameter is required. The BLINK attribute is not supported in the Motif interface. However, if you specify the BLINK attribute, it is displayed when the catalog is ported to other operating environments.

Examples: Defining Keys Using SAS Resources

Note: Most SAS documentation uses angle brackets (<>) to indicate optional syntax. However, in these examples, optional syntax is shown with square brackets ([ ]). The angle brackets that are shown in these examples are part of the syntax and should be entered exactly as shown.

In the following example, the sas-do-command action routine specifies that the COMMAND command is to override any existing definition for KP_0.

```
SAS.keyboardTranslations: #override
None<Key>KP_0: sas-do-command(COMMAND)
```

All other keys retain their current definitions.

The following example binds the key sequence Ctrl-K to the KEYS command and specifies that Ctrl-D deletes the character under the cursor. Commands entered in the Keys window for Ctrl-K and Ctrl-D have no effect.

```
SAS.keyboardTranslations: #override
  Ctrl<Key>k: sas-do-command(keys)\n  Ctrl<Key>d: sas-delete-char()
```

The following example specifies that the key associated with the keysym hpClearLine performs the command entered beside the MyClrLn label in the Keys window.

```
SAS.keyboardTranslations: #override
  <Key>hpClearLine : sas-function-key("ClearLn")
  SAS.keysWindowLabels: MyClrLn(ClearLn)
```

The character string that appears inside the parentheses in the SAS.keysWindowLabels resource must match the string entered as the parameter to the sas-function-key routine. The label (MyClrLn) can be any character string, and the keysym hpClearLine must be a valid keysym for your keyboard.
Customizing Fonts in UNIX Environments

Difference between the System Font and Fonts That Are Used in the Windowing Environment

SAS uses two main types of fonts:

- The system font is used in most dialog boxes and menus. SAS inherits the system font defined by the CDE `*.systemFont` resource. If this resource is not defined, SAS uses a Helvetica font.
- DMS fonts are used in SAS windows. You can change the SAS font either through the Fonts dialog box or by specifying the resources in your resources file. The font must be a fixed or monospace font.

Note: It is best to change fonts before invoking any applications. Changing fonts while applications are running might result in unexpected behavior.

How SAS Determines Which Font to Use

SAS determines the normal (not bold) default font as follows:

1. If you saved a font in `Sasuser.Profile.Dmsfont.Unxpath` through the Font dialog box, this font is used as the default normal font.
2. If you did not save a font through the Font dialog box, but you set the `SAS.DMSFont` resource, SAS uses the font specified by this resource as the default font.
3. If you did not set the `SAS.DMSFont` resource, SAS uses any font that matches the pattern `*Font`, which might be defined or inherited.
4. If you did not specify or inherit any resources matching `*Font`, but you did set the `SAS.DMSFontPattern` resource, SAS uses this resource to determine which font to use. The `SAS.DMSFontPattern` resource has no effect if any resources matching `*Font` are inherited or defined.
5. If no resources were set, SAS chooses a font from the fonts that are available on your X server.

If you did not specify a value for the `SAS.DMSboldFont` resource, SAS uses the default normal font to determine the default bold font. If an XLFD name is associated with the normal `SAS.DMSFont`, then SAS selects the matching bold font and loads it. If SAS cannot automatically select or load a bold font, the normal font is also used for the bold font.
In many cases, font names are given aliases so that a shorter name can be used to refer to a font for which an XLFD name is associated. The name used in determining a bold font is based on the XA_FONT font property for the normal font.

Customizing Fonts By Using the Fonts Dialog Box

Introduction to the Fonts Dialog Box

The Fonts dialog box enables you to change the windowing environment font for the entire SAS session. If you change the font, the font that you select is stored in SASUSER.PROFILE.DMSFONT.UNXPREFS and will be used in future SAS sessions.

How to Change the Default Font

You can change the default font by opening the Fonts dialog box. To open the Fonts dialog box, use one of the following methods:

- Issue the DLGFONT command in the command window.
- Select Tools ⇒ Options ⇒ Fonts.

![Figure 10.8 Fonts Dialog Box](image)

- Select a font name and, if desired, a size, weight, and slant. (Not all fonts are available in all sizes, weights, or slants.) The Sample field shows what the selected font looks like.
- Click OK to change the existing font to the selected font.

To return to the default font, click Default.
To cancel any changes and exit the Fonts dialog box, click **Cancel**.

## Specifying Font Resources

You can customize the fonts that are used in the SAS windowing environment with the following resources:

- **SAS.DMSFont**: font-name
  - Specifies the font that you want to be used as the default normal font. The default normal font is Courier.

- **SAS.DMSboldFont**: font-name
  - Specifies the font that you want to be used as the default bold font.

- **SAS.DMSDBfont**: font-name
  - Specifies the multi-byte normal character set font used by the SAS windowing system for operating environments that support multi-byte character sets.

- **SAS.DMSDBboldFont**: font-name
  - Specifies the multi-byte bold character set font used by the SAS windowing system for operating environments that support multi-byte character sets.

- **SAS.DMSfontPattern**: XLFD-pattern
  - Specifies an X Logical Font Description, or XLFD pattern that you want SAS to use to determine the windowing environment font. Most fonts in the X Window System are associated with an XLFD, which contains a number of different fields delimited by a hyphen (–) character. The fields in the XLFD indicate properties such as the font family name, weight, size, resolution, and whether the font is proportional or monospaced. See your X Window System documentation for more information about the XLFD and font names used with X.

  The **XLFD-pattern** that you specify for **SAS.DMSfontPattern** must contain the same number of fields as an XLFD. An asterisk (*) character means that any value is acceptable for that particular field. For example, the following pattern matches any font that has a regular slant, is not bold, is monospaced, and is an iso8859 font:

  ```
  SAS.DMSFontPattern: -*-*-r-*-*-m-*-iso8859-1
  ```

  SAS uses the **XLFD-pattern** to choose a font as follows:

  - SAS queries the X server for the list of fonts that match the **SAS.DMSfontPattern** resource.
  - SAS excludes all fonts that have X and Y resolution values different from the current X display, all fonts that have variable character cell sizing (such as proportional fonts), and all fonts that have point sizes smaller than 8 points or larger than 15 points. If this step results in an empty list, SAS chooses a generic (and usually fixed) font.
  - The font with the largest point size is chosen from the remaining list.

- **SAS.fontPattern**: XLFD-pattern
  - Specifies an XLFD font pattern that describes the candidate fonts used to resolve SAS graphics font requests. Using this pattern allows the user to optimize or control the use of X fonts within the context of various SAS graphics applications. The default value of * usually does not affect performance to a significant degree. You might want to restrict the font search if you are running SAS on a server with an excessive number of fonts or that is operating in performance-limited environment.
SAS systemFont: font-name
specifies the system font. The SAS font is used in SAS windows. The system font is used in most dialog boxes and menus. SAS typically inherits the system font from the font resources set by the X window environment, such as the Common Desktop Environment (CDE), or K Desktop Environment (KDE). If the *.systemFont resource, SAS uses a 12-point Helvetica font.

Specifying Font Aliases

Font Aliases

If your server does not provide fonts to match all of the fonts that are supplied by SAS, you can use font alias resources to substitute the fonts that are available on your system. (Ask your system administrator about the fonts that are available.) Use the following syntax to specify font aliases in your resource file:

SAS.supplied-fontAlias: substitute-family

supplied-font is the name of the font supplied by SAS. substitute-family is the family name of the font that you want to substitute.

CAUTION
Do not specify a SAS font as a font alias. There might be a conflict if you specify a font supplied by SAS as a font alias. Assigning this value to a font alias prevents the selection of any symbol fonts through the font selection dialog box, because they are specified as the Times Roman alias.

The following table lists SAS font alias resource names.

Table 10.1   SAS Font Alias Resources

<table>
<thead>
<tr>
<th>Resource Name</th>
<th>Class Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAS.timesRomanAlias</td>
<td>TimesRomanAlias</td>
</tr>
<tr>
<td>SAS.helveticaAlias</td>
<td>HelveticaAlias</td>
</tr>
<tr>
<td>SAS.courierAlias</td>
<td>CourierAlias</td>
</tr>
<tr>
<td>SAS.symbolAlias</td>
<td>SymbolAlias</td>
</tr>
<tr>
<td>SAS.avantGardeAlias</td>
<td>AvantGardeAlias</td>
</tr>
<tr>
<td>SAS.bookmanAlias</td>
<td>BookmanAlias</td>
</tr>
<tr>
<td>SAS.newCenturySchoolbookAlias</td>
<td>NewCenturySchoolbookAlias</td>
</tr>
<tr>
<td>SAS.palatinoAlias</td>
<td>PalatinoAlias</td>
</tr>
<tr>
<td>SAS.zapfChanceryAlias</td>
<td>ZapfChanceryAlias</td>
</tr>
</tbody>
</table>
Example: Substitute the Lucida Font for Palatino

Suppose that your system does not have a Palatino font, but has the following Lucida font:

```
b&h-lucida-bold-r-normal-sans-
   10-100-75-75-p-66-iso8859-1
```

To substitute Lucida for Palatino, include the following line in your resource file:

```
SAS.palatinoAlias: lucida
```
Customizing Colors By Using the SASCOLOR Window

You can use the SASCOLOR window to change the color and highlighting of specific elements of SAS windows. To open the SASCOLOR window, issue the SASCOLOR command or select Tools ⇒ Options ⇒ Colors:

Figure 10.9  SASCOLOR Window

To change a color for a window element, select the element name, and then select color and attribute that you want assigned to the element.

The BLINK attribute is not supported. The HIGHLIGHT attribute causes text to be displayed in bold font.

When you click Save, your changes are saved to the catalog entry Sasuser.Profile.Sas.Cparms.

Note: Close and reopen any active windows for new color settings to take effect.

For more information about the SASCOLOR window, see the online SAS Help and Documentation.

Syntax of the COLOR Command

You can use the COLOR command to set the color for specific elements of the active window:

```
color field-type <color|NEXT <highlight>>
```

- **field-type** specifies an area of the window such as background, command, border, message, and so on.

- **color** specifies a color such as blue (B), red (R), green (G), cyan (C), pink (P), yellow (Y), white (W), black (K), magenta (M), gray (A), brown (B), or orange (O).
NEXT changes the color to the next available color.

highlight can be H (which causes text to be displayed in a bold font), U (underlined), or R (reverse video). The BLINK attribute is not supported.

To save your changes, issue the WSAVE command. The changes are saved to Sasuser.Profile.Window.Wsave.

Note: The WSAVE command is not available for all SAS windows. For example, with SAS/FSP, changes are saved either through the EDPARMS window or the PARMS window. (To determine whether WSAVE is available for a SAS window, see the product documentation.)

For more information about the COLOR and WSAVE commands, see the online SAS Help and Documentation.

---

Defining Color Resources

Types of Color Resources

Color resources fall into two categories:

- foreground and background definitions
  These resources enable you to customize the RGB values that are used to define the 12 DMS colors. Because each color could be used as either a background color or a foreground color, you can specify different RGB values or color names for each color for each usage. For example, you can specify that when blue is used as a foreground color, color #0046ED is used, and when blue is used as a background color, CornflowerBlue is used.

- window element definitions
  These resources, which are referred to as CPARMS resources, enable you to specify which of the 12 DMS colors you want to use for each window element. For example, you can specify that message text is displayed in magenta.

These two types of resources work together. The CPARMS color values use the current foreground and background definitions. For example, the following resources specify that the background of your primary windows is CornflowerBlue:

```
SAS.blueBackgroundColor: CornflowerBlue
SAS.cparmBackground: DmBlue
```

Specifying RGB Values or Color Names for Foreground and Background Resources

SAS uses SAS.systemBackground, SAS.systemForeground, and the resources listed in the following table to determine the colors to be used in its windows.

```
SAS.systemForeground: color
```

specifies the color for the foreground system color in the SASCOLOR window.
SAS.systemBackground: color
specifies the color for the background system color in the SASCOLOR window.

SAS.systemSecondaryBackground: color
sets the system secondary background color and specifies the color for the secondary background system color in the SASCOLOR window.

You can specify color names such as MediumVioletRed or RGB values such as #0000FF for all of the foreground and background resources. See your X Window System documentation for information about RGB color values.

The following table lists all of the foreground and background color resources and their class names. All of these resources are of the type String.

Table 10.2  Foreground and Background Color Resources

<table>
<thead>
<tr>
<th>Resource Name</th>
<th>Class Name</th>
</tr>
</thead>

<td>BlueBackgroundColor</td>
</tr>
<tr>
<td>SAS.brownBackgroundColor</td>
<td>BrownBackgroundColor</td>
</tr>
</tbody>
</table>
Defining Colors and Attributes for Window Elements (CPARMS)

You can define the colors and attributes for specific window elements by assigning values to SAS resources known as CPARMS. Each CPARMS resource defines the color and attribute of a specific window element, such as the background in a secondary window or the border of a primary window.

You can specify multiple color and attribute names in the same resource definition, but only the final color and attribute are used:

```
SAS.cparmResource: DmColorName|DmAttrName\n\n<+DmColorName|DmAttrName>
```

Resource can be any of the CPARMS resources listed in the following table. All of these resources are of type DmColor, and their default values are dynamic—that is, the default values are determined at run time.

### Table 10.3 SAS CPARMS Resources

<table>
<thead>
<tr>
<th>Resource Name</th>
<th>Color and attribute settings</th>
<th>Class Name</th>
<th>Default Color</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>SAS.cparmBackgroundColor</td>
<td>for backgrounds within all primary windows displayed in a SAS session.</td>
<td>CparmBackgroundColor</td>
<td>DmWhite</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmBanner</td>
<td>for a banner within a window.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>Resource Name</td>
<td>Color and attribute settings</td>
<td>Class Name</td>
<td>Default Color</td>
<td></td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
<td>---------------------</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmBorder</td>
<td>for the border of a primary window.</td>
<td>CparmBackground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmByline</td>
<td>for BY lines written to the Output window.</td>
<td>CparmForeground</td>
<td>DmBlue</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmColumn</td>
<td>for text labels for column information. You can use this resource within the SAS editor to identify editing lines and in spreadsheet windows to label spreadsheets.</td>
<td>CparmForeground</td>
<td>DmBlue/Underline</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmCommand</td>
<td>for the command data entry field when menus are disabled.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmData</td>
<td>for general lines written to the Log window or the Output window.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmError</td>
<td>for ERROR lines that are written to the Log window or Output window.</td>
<td>CparmForeground</td>
<td>DmRed</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmFootnote</td>
<td>for FOOTNOTE lines written to the Output window.</td>
<td>CparmForeground</td>
<td>DmBlue</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmForeground</td>
<td>for all text fields within a SAS windowing environment window that can be edited.</td>
<td>CparmBackground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmHeader</td>
<td>for HEADER lines written to the Output window.</td>
<td>CparmForeground</td>
<td>DmBlue</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmHelpLink</td>
<td>for links to additional levels of information in the Help system.</td>
<td>CparmForeground</td>
<td>DmGreen/Underline</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmHelpMainTopic</td>
<td>for topic words or phrases in the Help system.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmHelpSubTopic</td>
<td>for topic words or phrases in the Help system.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>Resource Name</td>
<td>Color and attribute settings</td>
<td>Class Name</td>
<td>Default Color</td>
<td></td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
<td>------------------------</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmInfo</td>
<td>for text that is displayed in a window as an aid to the user. For example: Press Enter to continue</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmLabel</td>
<td>for text that precedes a widget. For example, the text Name: in the following example is a label: Name: _______________</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmMark</td>
<td>for areas that have been selected for operations such as FIND, CUT, and COPY.</td>
<td>CparmForeground</td>
<td>DmBlack/DmReverse</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmMessage</td>
<td>for the message field.</td>
<td>CparmForeground</td>
<td>DmRed</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmNote</td>
<td>for NOTE lines that are written to the Log window or the Output window.</td>
<td>CparmForeground</td>
<td>DmBlue</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmSecondaryBackground</td>
<td>for backgrounds in secondary windows.</td>
<td>CparmForeground</td>
<td>DmGray</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmSecondaryBorder</td>
<td>for the border of a secondary window.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmSource</td>
<td>for SAS source lines that are written to the Log window.</td>
<td>CparmForeground</td>
<td>DmBlack</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmText</td>
<td>for text labels for row information. You can use this resource within the SAS editor to identify editing lines and in spreadsheet windows to label spreadsheet rows.</td>
<td>CparmForeground</td>
<td>DmBlue</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmTitle</td>
<td>for TITLE lines written to the Output window.</td>
<td>CparmForeground</td>
<td>DmBlue</td>
<td></td>
</tr>
<tr>
<td>SAS.cparmWarning</td>
<td>for WARNING lines written to the Log window or the Output window.</td>
<td>CparmForeground</td>
<td>DmGreen</td>
<td></td>
</tr>
</tbody>
</table>

*DmColorName* can be any one of the following colors:
- DmBLUE
DmRED
DmPINK
DmGREEN
DmCYAN
DmYELLOW
DmWHITE
DmORANGE
DmBLACK
DmMAGENTA
DmGRAY
DmBROWN

_DmAttrName_ can be any one of the following attributes:

- DmHIGHLIGHT
- DmUNDERLINE
- DmREVERSE

For example, the following resources specify that all background colors are gray and all foreground colors are black:

```
SAS.cparmBackground: DmGRAY
SAS.cparmForeground: DmBLACK
```

These resources specify that errors should be displayed in red with reverse video, and warnings should be displayed in yellow with reverse video and a bold font:

```
SAS.cparmError: DmRED + DmREVERSE
SAS.cparmWarning: DmHIGHLIGHT + DmYELLOW + DmREVERSE
```

SAS looks for default CPARMS resources in two places:

- If your on-site SAS support personnel entered color and attribute settings in the SASHELP.BASE.SAS.CPARMS catalog entry, then these settings become the default for your site.
- If you saved settings in Sasuser.Profile.Sas.Cparms, then these settings override the settings specified for your site.

### Controlling Contrast

In some color combinations, text fields, buttons, check boxes, and other foreground categories might not be visible. The _SAS.dmsContrastCheck_ resource makes these categories legible.

```
SAS.dmsContrastCheck: True | False
```

controls whether contrast mapping is applied to non-graphic foreground colors in a SAS window. The default value is False. A value of True specifies that DMS foreground colors are remapped if necessary to produce a contrast. Some color usage based on graphic operations are not affected by this resource.
Controlling Drop-down Menus in UNIX Environments

Drop-down menus are controlled by the following resources:

- **SAS.pmenuOn**: `True` | `False`  
  forces the global PMENU state on regardless of the information stored by the WSAVE command. The WSAVE state of an individual window takes precedence over the global state. The default is `True`. (You can also use the PMENU ON and PMENU OFF commands to turn drop-down menus on and off.)

- **SAS.usePmenuMnemonics**: `True` | `False`  
  specifies whether mnemonics are attached to the drop-down menus for the current SAS session. The default is `True`.

Customizing Cut and Paste in UNIX Environments

Instructions for Cutting and Pasting Text

For instructions about cutting and pasting text, see “Selecting (Marking) Text in UNIX Environments” on page 174 and “Copying or Cutting and Pasting Selected Text in UNIX Environments” on page 177.

Types of Paste Buffers

There are four SAS paste buffers. Each SAS paste buffer is associated with an X paste buffer:

- **XPRIMARY**:  
  is associated with X primary selection (PRIMARY).

- **XSCNDARY**:  
  is associated with the X secondary selection (SECONDARY).

- **XCLIPBRD**:  
  is associated with the X clipboard selection (CLIPBOARD). This paste buffer enables you to use the MIT X Consortium xclipboard client with SAS.

- **XTERM**:  
  is associated with the paste buffer used by the xterm client. XTERM is the default buffer. DEFAULT is an alias for XTERM. If you copy or cut text into the
XTERM buffer, the text is actually copied or cut into all four of the paste buffers. When you paste text from the XTERM buffer, the text is pasted from the XPRIMARY buffer.

XCUTn
is associated with X cut buffer n where 0 <= n <= 7.

---

### Selecting a Paste Buffer

If you are not sure which X data exchange protocols your other X clients are using, you should use the XTERM paste buffer. You can specify your default paste buffer with the SAS.defaultPasteBuffer resource:

```
SAS.defaultPasteBuffer: XTERM
```

If you know that the X clients in your workstation environment all use the X PRIMARY selections to exchange data, you should use the XPRIMARY paste buffer:

```
SAS.defaultPasteBuffer: XPRIMARY
```

This specification uses both SAS and X resources more efficiently and provides for the on-demand transfer of data between clients.

Solaris OpenWindows desktop clients use the CLIPBOARD selection as the basis for their copy-and-paste operations. If you use the SAS XCLIPBRD paste buffer, you can exchange text directly with these clients.

You can also use the SAS XCLIPBRD paste buffer to interact with Motif clients that use the Motif clipboard mechanism for text exchanges. This clipboard mechanism makes it unnecessary to have a dedicated client such as xclipboard. For example, you can use XCLIPBRD to exchange text directly with the Motif xmeditor application when you select the **Cut**, **Copy**, or **Paste** items from the xmeditor **Edit** drop-down menu.

The Motif quick-copy data exchange and Motif clipboard data exchange mechanisms are specific to the Motif interface toolkit and are not currently supported as SAS paste buffers. However, some dialog boxes, such as the File Selection dialog box, use Motif interface text widgets. In these dialog boxes, the Motif quick copy and clipboard data exchange mechanisms are available.

---

### Manipulating Text Using a Paste Buffer

If you want SAS to automatically copy selected text into your paste buffer every time you select text, specify your paste buffer name in the SAS.markPasteBuffer resource:

```
SAS.markPasteBuffer: XTERM
```

Alternatively, because DEFAULT is an alias for XTERM, you could specify the following:

```
SAS.markPasteBuffer: DEFAULT
```

The **SAS.markPasteBuffer** definition causes SAS to automatically issue a STORE command whenever you select text.
The STORE command, as well as the CUT and PASTE commands, support a BUFFER= option that specifies which buffer to use. When these commands are issued from function keys or drop-down menus whose definitions do not include the BUFFER= option, if the SAS.markPasteBuffer resource is not defined, these commands use BUFFER=DEFAULT. If this resource is defined, these commands use BUFFER=buffer-name.

You can customize your normal cut, copy, or paste keys to issue any of these commands with the BUFFER= option. For example, you can override the SAS.keyboardTranslations definition for the osfCopy and osfPaste keys with the following specifications:

```sas
SAS.keyboardTranslations: #override 
  <Key>osfCopy: sas-do-command("STORE BUFFER=XCLIPBRD") \n  <Key>osfPaste: sas-do-command("PASTE BUFFER=XCLIPBRD")
```

For more information about customizing keys, see “Customizing Key Definitions in UNIX Environments” on page 208.

---

Notes about Preserving Text and Attribute Information

When you cut or copy and paste text between SAS sessions using the XTERM, XPRIMARY, or XSCNDARY paste buffers, the color and attribute information is preserved. However, if you copy and paste the same text into an xterm window while using the vi editor, the color and attribute information is lost. If you change the definition for SAS.defaultPasteBuffer and SAS.markPasteBuffer to XCUT0, then the text and color attributes are not retained when you copy and paste text between two SAS sessions.

When you use the xclipboard client, SAS text attributes are not preserved in exchanges made between SAS sessions. However, when you use the XCLIPBRD paste buffer without a clipboard manager such as the xclipboard client, SAS text attributes are preserved in exchanges between SAS sessions.

---

Customizing Session Workspace, Session Gravity, and Window Sizes in UNIX Environments

SAS uses the following resources to determine the size of the session workspace, the gravity of the workspace, and the size of the windows. The default values for these resources are listed in Table 10.4 on page 237.

- **SAS.awsResizePolicy**: grow | fixed
  - grow: controls the policy for resizing AWS windows as interior windows are added and removed. The following values are valid:
    - grow: the AWS window attempts to grow anytime an interior window is grown or moved, in order to show all interior windows, but it does not shrink to remove dead areas.
fixed
the AWS window attempts to size itself to the size of the first interior window and
does not attempt any further size changes.

**SAS.maxWindowHeight**: *units*
specifies the number of units for the maximum height of a window. The unit is
specified by the `SAS.windowUnitType` resource.

**SAS.maxWindowWidth**: *units*
specifies the number of units for the maximum width of a window. The unit is
specified by the `SAS.windowUnitType` resource.

**SAS.noAWS**: True | False
controls whether each of your application's windows appears in its own native
window rather than in an application workspace (AWS). The default is True; each
application runs in its own native window.

**SAS.scrollBarSize**: *pixels*
specifies the default size of the scroll bar in pixels.

**SAS.sessionGravity**: value
controls the region of the screen where SAS attempt to place its windows. This
resource might be ignored by some window manager configurations. Possible
values include the following:

- CenterGravity
- EastGravity
- WestGravity
- SouthGravity
- NorthGravity
- SouthEastGravity
- NorthEastGravity
- SouthWestGravity
- NorthWestGravity

**SAS.sessionGravityXOffset**: *offset*
specifies an x offset to be added when SAS attempts to place a window in the
gravity region.

**SAS.sessionGravityYOffset**: *offset*
specifies a y offset to be added when SAS attempts to place a window in the
gravity region.

**SAS.windowHeight**: *units*
specifies the number of units for the default height of a window. The unit is
specified by the `SAS.windowUnitType` resource.

**SAS.windowUnitType**: character | pixel | percentage
specifies the unit type for `SAS.windowWidth`, `SAS.windowHeight`,
`SAS.maxWindowWidth`, and `SAS.maxWindowHeight`. Possible values include the
following:

- character
  units specify the number of rows and columns.

- pixel
  units specify the number of pixels.
percentage
units specify the percentage of the screen.

\texttt{SAS.windowWidth: units}
specifies the number of units for the default width of a window. The unit is
specified by the \texttt{SAS.windowUnitType} resource.

---

### Specifying User-Defined Icons in UNIX Environments

#### Why Specify User-Defined Icons?

You can add your own icons to those icons that are supplied with SAS. For
example, if you want to use your own color icons in the toolbox, define the
\texttt{SAS.colorUiconPath}, \texttt{SAS.colorUiconCount}, and \texttt{SAS.sasUiconx} resources. Then,
when you are defining tools in the Tool Editor, the Tool Editor includes your icons in
the display of icons that you can choose for each tool.

#### How SAS Locates a User-Defined Icon

The resource name that is used to locate the icon bitmap filename for user icon
number \(x\) is \texttt{SAS.sasUiconx}. For example, the following resource defines the
filename \texttt{myicon} for the user icon 1:

\texttt{SAS.sasUicon1: myicon}

If the resource name is not defined, SAS generates a filename of the form
\texttt{sasui\nnn.xbm} or \texttt{sasui\nnn.xpm}. The path elements from the \texttt{SAS.uiconPath} or
\texttt{SAS.colorUiconPath} resource are searched in sequence until the icon file is found
or until the search path is exhausted.

For example, the following set of X resources defines a collection of color icons:

\texttt{SAS.colorUiconPath: /users/jackaroe/pixmaps/}
\texttt{SAS.colorUiconCount: 7}
\texttt{SAS.sasUicon1: adsetup}
\texttt{SAS.sasUicon2: adverse}
\texttt{SAS.sasUicon3: altmenu}
\texttt{SAS.sasUicon4: batch}
\texttt{SAS.sasUicon5: is}
\texttt{SAS.sasUicon6: patgrps}
\texttt{SAS.sasUicon7: pctchg}

The Motif interface searches for icon \texttt{sasUicon1} in a file named \texttt{/users/jackaroe/pixmaps/adsetup.xpm}. 

---
X Resources for Specifying User-Defined Icons

SAS uses the following resources to determine the number of user-defined icons that are available and their location.

**SAS.colorUiconPath: search-path**
specifies the file search path for locating user-defined color icon files. This string resource specifies the directory paths to be searched for an icon file. These files should be in X Pixmap (xpm) format. Use a comma to separate individual directory pathnames. For example, the following string first searches for icon files in the /usr/lib/X11/pixmaps directory and then in the /usr/lib/X11/pixmaps/SAS directory:

```
SAS.colorUiconPath : /usr/lib/X11/pixmaps, \\
/usr/lib/X11/pixmaps/SAS
```

**SAS.colorUiconCount: num-icons**
specifies the number of user-defined color icons that are available for SAS to use.

**SAS.uiconPath: search-path**
specifies the file search path for locating user-defined icon bitmap files. This string resource specifies the directory paths to be searched for an icon file. These files should be in X Bitmap (xbm) format. Use a comma to separate individual directory pathnames. For example, the following string will first search for bitmap files in the /usr/lib/X11/bitmaps directory and then in the /usr/lib/X11/bitmaps/SAS directory:

```
SAS.uiconPath : /usr/lib/X11/bitmaps, \\
/usr/lib/X11/bitmaps/SAS
```

**SAS.sasUiconx: name**
associates a value with the filename of an X Bitmap or Pixmap file. x is a number assigned to the file. A file extension of .xbm or .xpm is automatically supplied.

---

Miscellaneous Resources in UNIX Environments

You can also customize the following resources:

**SAS.altVisualId: ID**
specifies a visual type ID.

**SAS.autoSaveInterval: minutes**
specifies how often (in number of minutes) that the data from the Program Editor window should be saved.
SAS.autoSaveOn: True | False
specifies that data from the Program Editor window should be saved to a file at intervals specified by the SAS.autoSaveInterval resource.

SAS.confirmSASExit: True | False
controls whether SAS displays the Exit dialog box when you enter the DLGENDR command or select File ⇒ Exit. The default is True.

SAS.defaultCommandWindow: True | False
specifies whether the command window is invoked when you start your SAS session. The default is True.

SAS.directory: directory-pathname
specifies the directory that you want when you first invoke the Open dialog box. By default, the Open dialog box uses the current directory.

SAS.helpBrowser: pathname
specifies the pathname of the World Wide Web browser to use for viewing the online Help or when the WBROWSE command is issued.

SAS.htmlUsePassword: True | False
specifies whether SAS prompts you to enter your password before sending HTML files to your browser. The default value is True.

SAS.insertModeOn: True | False
controls the editing mode in SAS editor windows. The default is False (overtype).

SAS.noDoCommandRecall: True | False
controls whether SAS commands that are submitted through the sas-do-command() action routine are recorded in the command recall buffer. The default value of True causes commands to be omitted from the command recall buffer; a value of False causes them to be recorded.

SAS.pattern: default-pattern
specifies the default pattern that you want to be used as the file filter when you first invoke the Open and Import Image dialog boxes. This pattern is displayed in the text field at the top of the dialog box. By default, the dialog box uses the first filter in the File type list. The pattern resource has no effect on the File type field.

SAS.selectTimeout: seconds
specifies the X Toolkit selection conversion time-out value in units of seconds. This time-out value determines the amount of time that SAS waits for a request to convert an X Toolkit selection to complete. The default value should be adequate in most cases.

SAS.startupLogo: xpm-filename | None | ""
specifies the XPM file that you want SAS to display when it is initialized. If the string is empty, SAS uses the default logo.

SAS.startSessionManager: True | False
specifies whether SAS automatically starts the SAS Session Manager when a new SAS session is started. Using your own host editor with SAS requires that the SAS Session Manager be running. The default is True.

SAS.suppressMenuIcons: True | False
specifies whether SAS displays any menu icons other than the check box and toggle button icons in cascade or pop-up menus. Suppressing the icons reduces memory usage and improves how quickly the menus are displayed on slower X servers. The default is False.
SAS.suppressTutorialDialog: True  |  False
specifies whether SAS displays the Getting Started Tutorial dialog box at the start of your SAS session. True suppresses the dialog box. You might want to suppress this dialog box if you have previously used SAS. The default is False.

SAS.useNativeXmTextTranslations: True  |  False
specifies whether any XmText widget translations are inherited by all instances of the Text, Combo Box, and Spin Box widgets used by the SAS X Motif user interface. When the value is False, the SAS keys windows translations supersede any user or system-supplied XmText translations. The default value is True.

The following example shows SAS XmText translations:

SAS*XmText*translations:   #override

Ctrl<Key>e:end-of-line()
Ctrl<Key>u:delete-to-start-of-line()
Ctrl<Key>k:delete-to-end-of-line()
Ctrl<Key>f:forward-character()
Ctrl<Key>b:backward-character()
Ctrl<Key>a:beginning-of-line()
Ctrl<Key>c:copy-clipboard()
Ctrl<Key>v:paste-clipboard()

SAS.wsaveAllExit: True  |  False
specifies whether SAS should issue the WSAVE ALL command when you end your session. This command saves the global settings, such as window color and window position, that are in effect for all windows that are currently open. The default is False.

Note: For the WSAVE command to work, your window manager must support explicit window placement. See the documentation for your window manager to determine how to configure your window manager. For example, if you are running Exceed, open the Screen Definition Settings dialog box and deselect Cascade Windows.

---

Summary of X Resources for SAS in UNIX Environments

The following table lists the instance and class names, type, and default values for many of the SAS resources. See the following sections for additional resources of specific types:

- "Specifying Font Aliases" on page 220
- "Defining Color Resources" on page 223
- "Defining Colors and Attributes for Window Elements (CPARMS)" on page 225

PART 3

Data Considerations

Chapter 11

Data Representation
11

Data Representation

**Numeric Variable Length and Precision in UNIX Environments**

The default length of numeric variables in SAS data sets is 8 bytes. (You can control the length of SAS numeric variables with the LENGTH or ATTRIB statements in the DATA step.)

The issue of numeric precision affects the return values of almost all SAS math functions and many numeric values returned from SAS procedures. Numeric values in SAS for UNIX are represented as IEEE double-precision floating-point numbers. The decimal precision of a full 8-byte number is effectively 15 decimal digits.

The following table specifies the significant digits and largest integer that can be stored exactly in SAS numeric variables.

<table>
<thead>
<tr>
<th>Length in Bytes</th>
<th>Significant Digits Retained</th>
<th>Largest Integer Represented Exactly</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3</td>
<td>8,192</td>
</tr>
<tr>
<td>4</td>
<td>6</td>
<td>2,097,152</td>
</tr>
<tr>
<td>5</td>
<td>8</td>
<td>536,870,912</td>
</tr>
<tr>
<td>6</td>
<td>11</td>
<td>137,438,953,472</td>
</tr>
<tr>
<td>7</td>
<td>13</td>
<td>35,184,372,088,832</td>
</tr>
<tr>
<td>8</td>
<td>15</td>
<td>9,007,199,254,740,992</td>
</tr>
</tbody>
</table>
When you are specifying variable lengths, keep in mind that the length of a variable affects both the amount of disk space used and the number of I/O operations required to read and write the data set.

If you know that the value of a numeric variable will be an integer between -8192 and 8192 inclusive, you can use a length of 3 to store the number and thus save space in your data set. For example:

```sas
data mydata;
  length num 3;
  ...more SAS statements...
run;
```

Numeric dummy variables (variables whose only purpose is to hold 0 or 1) can be stored in a variable whose length is 3 bytes.

**CAUTION**

*Use the LENGTH statement to reduce length only for variables whose values are always integers.* Fractional numbers lose precision if they are truncated. In addition, you must ensure that the values of your variable are always represented exactly in the number of bytes that you specify. You can do this programatically in a DATA step with the TRUNC function. No warnings or errors are issued when the length that you specify in the LENGTH statement results in the truncation of data.

For more information about specifying variable lengths and optimizing system performance, see *SAS Language Reference: Concepts*.

---

**Missing Values in UNIX Environments**

In SAS on UNIX, missing values are represented by IEEE Not-a-Number values. An IEEE Not-a-Number value is an IEEE floating-point bit pattern that represents something other than a valid numeric value. These numbers are not computationally derivable.

---

**Reading and Writing Binary Data in UNIX Environments**

Different computers store numeric binary data in different forms. If you try to move binary data in flat files across systems that are incompatible, problems will occur. A safer way to move data is by using SAS data sets.

SAS provides several sets of informats and formats for handling binary data. Some of these informats and formats are host dependent. For example, the IBw.d, PDw.d, PIBw.d, and RBw.d informats and formats read and write data in native mode. That is, they use the byte-ordering system that is standard for the computer.
Converting a UNIX Datetime Value to a SAS Datetime Value

A UNIX datetime value is stored as the number of seconds since January 1, 1970. A SAS datetime value is stored as the number of seconds since January 1, 1960. To convert a UNIX datetime value to a SAS datetime value, you must add 10 years in seconds to the UNIX datetime value.

The DHMS function converts a UNIX datetime value to a SAS datetime value, as shown in the example below:

```sas
data UNIX_to_SAS;
  input UNIX_datetime;
  SAS_datetime = dhms('01jan1970'd, 0,0, UNIX_datetime);
  format SAS_datetime datetime20.;
datalines;
1285560000
1313518500
1328414200
;
proc print data=UNIX_to_SAS;
run;
```

The following output displays the results.

*Figure 11.1 Conversion of a UNIX Datetime Value to a SAS Datetime Value*

For more information, see “DHMS Function” in *SAS Functions and CALL Routines: Reference.*

SAS Commands under UNIX

This section describes commands that you can enter on the command line in the windowing environment of SAS. The commands that are described here have behavior or syntax that is specific to UNIX environments. Each command description includes a brief "UNIX specifics" section that explains which aspect of the command is specific to UNIX. If the information under "UNIX specifics" says "all," then the command applies to the UNIX operating environment and is described only in this document.

The following commands are not supported in UNIX environments:

- CASCADE
- RESIZE
- WGROW
- DCALC
- SCROLLBAR
- WMOVE
- ICON
- SMARK
- WSHRINK
- PCLEAR
- TILE
- ZOOM

Dictionary

AUTOSCROLL Command: UNIX

Specifies how often the Log and Output windows scroll to display output.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: valid arguments and default values

Syntax

AUTOSCROLL<\n>

Optional Argument

\n
specifies the number of lines that the window should scroll when it receives a line of data that cannot fit.

Details

The AUTOSCROLL command controls the scrolling of lines as they are written to the Log and Output windows. The default value for AUTOSCROLL in the Log and Output windows is 1. Processing is slower when AUTOSCROLL displays one line at
a time. To expedite processing, you can specify a greater AUTOSCROLL value in your autoexec.sas file. Specifying a value of 0 optimizes processing and results in the fastest scrolling (similar to jump scrolling in xterm windows). To add the AUTOSCROLL command to your autoexec.sas file, you must use the DM command. The following example maximizes scrolling in both the Log and Output windows:

dm 'output; autoscroll 0; log; autoscroll 0; pgm;';

**CAPS Command: UNIX**

Changes the default case of text.

Category: Text Editing

Restriction: This command is not included in SAS Viya.

UNIX specifics: all

**Syntax**

```
CAPS <ON | OFF>
```

**Optional Arguments**

- **ON**
  
  turns capitalization on.

- **OFF**
  
  turns capitalization off.

**COLOR Command: UNIX**

Specifies the color and highlighting of selected portions of a window.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: valid field types and attributes

**Syntax**

```
COLOR field-type color | NEXT <highlight>
```

**Required Arguments**

- **field-type**
  
  specifies an area of the window such as background, command, border, message, and so on.

**color**

specifies a color such as blue (B), red (R), green (G), cyan (C), pink (P), yellow (Y), white (W), black (K), magenta (M), gray (A), brown (B), or orange (O).

**NEXT**

changes the color to the next available color.

**Optional Argument**

**highlight**

can be H (which causes text to be displayed in a bold font), U (underlined), or R (reverse video). The BLINK attribute is not supported.

**Details**

Under UNIX, you cannot use the COLOR command to change the colors in these field types: BORDER, MENU, MENUBORDER, SCROLLBAR, or TITLE. Also, the H (HIGHLIGHT) and B (BLINK) attributes are not supported. For more information about the COLOR command, see the online Help for the Program Editor window.

---

**DLGABOUT Command: UNIX**

Opens the About SAS dialog box.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: all

**Syntax**

**DLGABOUT**

**Details**

The About SAS dialog box displays information such as the release of SAS that you are running, your site number, the operating system, the version of Motif that you are using, and the color information from your PC.

To access this dialog box from the menu, select Help ⇒ About SAS 9.

---

**DLGCDIR Command: UNIX**

Opens the Change Working Directory dialog box.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: all
Syntax

**DLGCDIR**

Details

The Change Working Directory dialog box enables you to select a new working directory. To access this dialog box from the menu, select **Tools ➔ Options ➔ Change Directory**.

---

**DLGENDR Command: UNIX**

Opens the Exit dialog box.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: all

Syntax

**DLGENDR**

Details

The Exit dialog box prompts you to confirm that you want to exit SAS. If you choose **OK**, the SAS session ends. If you have set the `SAS.confirmSASExit` resource to **False**, this command becomes equivalent to the **BYE** command. To access this dialog box from the menu, select **File ➔ Exit**.

See Also

"Miscellaneous Resources in UNIX Environments" on page 234

---

**DLGFIND Command: UNIX**

Opens the Find dialog box.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: all

Syntax

**DLGFIND**
Details

The Find dialog box enables you to search for text strings. To access this dialog box from the menu, select Edit ⇒ Find.

See Also

Commands:
- “DLGREPLACE Command: UNIX” on page 256

DLGFONT Command: UNIX

Opens the Fonts dialog box.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

DLGFONT

Details

The Font dialog box enables you to dynamically change the SAS font. To access this dialog box from the menu, select Tools ⇒ Options ⇒ Fonts.

See Also

Commands:
- “SETDMSFONT Command: UNIX” on page 265

Other References:
- “Customizing Fonts in UNIX Environments” on page 217

DLGOPEN Command: UNIX

Opens the Open dialog box.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all
Syntax

**DLGOPEN** `<FILTERS='filters'>` `<IMPORT>` `<SUBMIT | NOSUBMIT>` `<VERIFY>`

Optional Arguments

**FILTERS='filters'**
specifies one or more file filters to use as search criteria when displaying files. For example, the following command displays all files in the current directory that have a `.sas` extension and adds `*.txt` to the File type box in the dialog box:

```
DLGOPEN FILTERS='*.sas *.txt'
```

You can specify multiple filters; they all appear in the box. If you do not specify any filters, the dialog box displays a default list. See the description of the **SAS.pattern** resource in "Miscellaneous Resources in UNIX Environments" on page 234 for information about specifying a default file pattern.

**IMPORT**
invokes the Import Image dialog box, which enables you to import graphic files to SAS/GRAPH applications.

**SUBMIT | NOSUBMIT**
specifies whether the SUBMIT command is pushed after the file is opened. The default value is NOSUBMIT.

**VERIFY**
checks whether the DLGOPEN command is appropriate for the active window.

Details

The Open and Import Image dialog boxes enable you to select a file to read into the active window. If the active window is a SAS/GRAPH window, then the Import Image dialog box is displayed. Otherwise, the Open dialog box is displayed. To access these dialog boxes from the menu, select **File ➔ Open** or **File ➔ Import Image**.

For more information, see "Adding Images to SAS/GRAPH Output" in **SAS/GRAPH: Reference**.

---

**DLG_PREF Command: UNIX**

Opens the Preferences dialog box.

**Category:** SAS Windowing Environment

**Restriction:** This command is not included in SAS Viya.

**UNIX specifics:** all

Syntax

**DLG_PREF**
Details

The Preferences dialog box enables you to dynamically change certain resource settings. To access this dialog box from the menu, select Tools ⇔ Options ⇔ Preferences.

See Also

"Modifying X Resources through the Preferences Dialog Box" on page 189

DLGREPLACE Command: UNIX

Opens the Change dialog box.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

DLGREPLACE

Details

The Change dialog box enables you to search for and replace text strings. To access this dialog box from the menu, select Edit ⇔ Replace.

See Also

Commands:
- "DLGFIND Command: UNIX" on page 253

DLGSAVE Command: UNIX

Opens the Save As or Export dialog box.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

DLGSAVE <FILTERS='filters'> <EXPORT> <VERIFY>
Optional Arguments

FILTERS='filters'
specifies one or more file filters to use as search criteria when displaying files. For example, the following command displays all files in the current directory that have a .sas extension and adds *.txt to the File type box in the dialog box:

```
DLGSAVE FILTERS="*.sas *.txt"
```

You can specify multiple filters; they all appear in the dialog box. If you do not specify any filters, the dialog box displays a default list.

EXPORT
invokes the Export dialog box, enabling you to export graphic files in your SAS session.

VERIFY
checks whether the DLGSAVE command is appropriate for the active window.

Details
To access this dialog box from the menu, select File ➔ Save as or File ➔ Export as Image.

---

DLGSCRDUMP Command: UNIX

Saves the active SAS/GRAPH window as an image file using the filename and file type that you specify.

**Category:** SAS Windowing Environment

**Restriction:** This command is not included in SAS Viya.

**UNIX specifics:** all

**Syntax**

```
DLGSCRDUMP <'filename.ext' 'FORMAT=file-type'>
```

**Details**

DLGSCRDUMP saves the active SAS/GRAPH window as an image file by using the filename and file type that you specify. If you do not specify arguments, DLGSCRDUMP opens the Export dialog box and enables you to choose a filename and file type. You can save displays in any image format that is supported by SAS/GRAPH. For details about specifying images, see "Adding Images to SAS/GRAPH Output" in SAS/GRAPH: Reference.

---

DLGSMAIL Command: UNIX

Opens the Send Mail dialog box.

**Category:** SAS Windowing Environment

**Restriction:** This command is not included in SAS Viya.
UNIX specifics: all

Syntax

DLGSMAIL

Details

The Send Mail dialog box enables you to send electronic mail while working in SAS. To access this dialog box from the menu, select File → Send mail.

FILE Command: UNIX

Writes the contents of the current window to an external file.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: valid values for encoding-value and host-options

Syntax

FILE <file-specification> <ENCODING='encoding-value'> <portable-options> <host-options>

Optional Arguments

file-specification

can be any of the following:

can be any of the following:

single filename

SAS writes the file in the current directory. If you enclose the filename in quotation marks, SAS uses the filename exactly as you specify it. If you do not enclose the filename in quotation marks and if you do not specify a file extension, SAS uses .sas, .log, or .lst, depending on whether you issue the command from the Program Editor, Log, or Output window.
entire pathname
SAS does not assume any file extensions, even if you do not enclose the pathname in quotation marks.

fileref
SAS specifies a fileref to assign to an external file.

ENCODING='encoding-value'
specifies the encoding to use when writing to the output file. The value for ENCODING= indicates that the output file has a different encoding from the current session encoding.

When you write data to the output file, SAS transcodes the data from the session encoding to the specified encoding.

For valid encoding values, see “Overview to SAS Language Elements That Use Encoding Values” in SAS National Language Support (NLS): Reference Guide.

portable-options
are options for the FILE command that are valid in all operating environments. For more information about these options, see SAS System Options: Reference.

host-options
are specific to UNIX environments. These options can be any of the following:

BLKSIZE=BLK=
specifies the number of bytes that are physically written in one I/O operation. The default is 8K. The maximum is 1G–1.

LRECL=
specifies the logical record length. Its value depends on the record format in effect (RECFM). In SAS 9.4, the default value for LRECL= is 32,767. If you are using fixed length records (RECFM=F), the default value for LRECL= is 256. The maximum record length is 1G.

If RECFM=F, then the value for the LRECL= option determines the length of each output record. The output record is truncated or padded with spaces to fit the specified size.

If RECFM=N, then the value for the LRECL= option must be at least 256.

If RECFM=V, then the value for the LRECL= option determines the maximum record length. Records that are longer than the specified length are truncated.

NEW
OLD
indicates that a new file is to be opened for output. If the file already exists, then it is deleted and re-created. This is the default action.

RECFM=
specifies the record format. Values for the RECFM= option are listed below:

D default format (same as variable).
F fixed format. That is, each record has the same length. Do not use RECFM=F for external files that contain carriage-control characters.
N binary format. The file consists of a stream of bytes with no record boundaries.
P print format. SAS writes carriage-control characters.
V variable format. Each record ends with a newline character.
S370V variable S370 record format (V).
S370VB variable block S370 record format (VB).
S370VBS variable block with spanned records S370 record format (VBS).

UNBUF tells SAS not to perform buffered writes to the file on any subsequent FILE statement. This option applies especially when you are writing to a data collection device.

Details
If you do not enter a file specification, SAS uses the filename from the previous FILE or INCLUDE command. In this case, SAS first asks whether you want to overwrite the file. If you have not issued any FILE or INCLUDE commands, you receive an error message that indicates that no default file exists.

FILL Command: UNIX
Specifies the fill character.
Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: default character

Syntax
FILL <fill-character>

Optional Argument
fill-character specifies the character to be used to fill out a line.
Under UNIX, the default fill character is an underscore (_).

FONTLIST Command: UNIX
Opens the Select Font window, which lists available software fonts.
Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all
Syntax

FONTLIST

Details

The FONTLIST command opens windows that list all of the software fonts that are available in your operating environment. This feature is useful if you want to choose a font to use in a SAS program, typically with a FONT= or FTEXT= option.

Issuing the FONTLIST command from the SAS command line opens the Select Font window, which contains two buttons, Copy and System. Clicking System opens the Fonts window, from which you can select and preview all available system fonts. After you select the desired font and font attributes, click OK. The Select Font window reopens with your selected font name displayed. Clicking Copy places the font name in the copy buffer so that you can paste the selected font name into your SAS program.

GSUBMIT Command: UNIX

Submits SAS code stored in a paste buffer.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: valid buffer names

Syntax

GSUBMIT BUF=buffer-name | "statement-1; statement-n;"

Required Arguments

buffer-name

can be XPRIMARY, XSCNDARY, XCLIPBRD, XTERM, or XCUTn where 0<=n<=7. For more information, see “Customizing Cut and Paste in UNIX Environments” on page 229.

statement

can be any SAS statement.

HOME Command: UNIX

Toggles the cursor position between the current position and the command line.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: keyboard equivalent
Syntax
HOSTEDIT

Details
Keyboards vary among the different UNIX operating environments. To determine which key is assigned to the HOME command, look in the Keys window. To open the Keys window, issue the KEYS command.

See Also
“Customizing Key Definitions in UNIX Environments” on page 208

HOSTEDIT Command: UNIX
Starts the UNIX editor, specified by the EDITCMD system option, in the current window.
Category: SAS Windowing Environment
Alias: HED
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax
HOSTEDIT

Details
When you issue the HOSTEDIT command from a SAS text editor window, the contents of the buffer for that window are written to a temporary file in the /tmp directory. A command invoking the host editor that was specified in the EDITCMD system option is passed to the SAS Session Manager. The SAS Session Manager issues the command to the operating environment to invoke the editor for the temporary file.
The X display that is used with the HOSTEDIT command is the same one that is used with your SAS session.

See Also
System Options:
- “EDITCMD System Option: UNIX” on page 394

Other References:
- “Configuring SAS for Host Editor Support in UNIX Environments” on page 183
INCLUDE Command: UNIX

Copies the entire contents of an external file into the current window.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: valid values for encoding-value and portable-options

Syntax

```
INCLUDE <file-specification> <ENCODING='encoding-value'> <portable-options> <host-options>
```

Optional Arguments

**file-specification**

can be any of the following:

- a single filename. SAS searches for the file in the current directory. If you enclose the filename in quotation marks, then SAS uses the filename exactly as you specify it. If you do not enclose the filename in quotation marks and if you do not specify a file extension, then SAS searches for .sas.
- an entire pathname. SAS does not assume any file extensions, even if you do not enclose the pathname in quotation marks.
- a fileref.

**ENCODING='encoding-value'**

specifies the encoding to use when reading from the external file. The value for ENCODING= indicates that the external file has a different encoding from the current session encoding.

When you read data from an external file, SAS transcodes the data from the specified encoding to the session encoding.

For valid encoding values, see “Overview to SAS Language Elements That Use Encoding Values” in SAS National Language Support (NLS): Reference Guide.

**portable-options**

are options for the INCLUDE command that are valid in all operating environments. See SAS System Options: Reference for information about these options.

**host-options**

are specific to UNIX environments. These options can be any of the following:

- `BLKSIZE=`
- `BLK=`
  - specifies the number of bytes that are physically read in one I/O operation. The default is 8K. The maximum is 1G–1.
- `LRECL=`
  - specifies the logical record length. Its value depends on the record format in effect (RECFM). In SAS 9.4, the default value for LRECL= is 32,767. If you
are using fixed length records, (RECFM=F), the default value for LRECL= is 256. The maximum record length is 1G.

- If RECFM=F, then the value for the LRECL= option determines the number of bytes to be read as one record.
- If RECFM=N, then the value for the LRECL= option must be at least 256.
- If RECFM=V, then the value for the LRECL= option determines the maximum record length. Records that are longer than the specified length are truncated.

**RECFM=**
specifies the record format. Values for the RECFM= option are listed below:

- **D** default format (same as variable).
- **F** fixed format. That is, each record has the same length.
- **N** binary format. The file consists of a stream of bytes with no record boundaries.
- **P** print format.
- **V** variable format. Each record ends with a newline character.

**Details**
If you do not enter a file specification, then SAS uses the filename from the previous FILE or INCLUDE command. In this case, SAS first asks whether you want to overwrite the file. If you have not issued any FILE or INCLUDE commands, then you receive an error message to indicate that no default file exists.

---

**SETAUTOSAVE Command: UNIX**

Turns autosave on and off.

**Category:** SAS Windowing Environment

**Restriction:** This command is not included in SAS Viya.

**UNIX specifics:** all

**Syntax**

```
SETAUTOSAVE <ON | OFF>
```

**Details**

The SETAUTOSAVE command turns autosave on or off for the Program Editor. However, the value set for autosave in the Preferences dialog box has precedence. To open the Preferences dialog box, select **Tools ➤ Options ➤ Preferences**. Autosave is controlled by the **Backup Documents** check box on the DMS tab. On this tab, there is also a field in which you can specify the interval for these backups.

If you turn autosave on using the SETAUTOSAVE command and the **Backup Documents** check box is selected, then SAS automatically saves the contents of
the Program Editor into a file named `pgm.asv` in your current directory at the interval specified on the **DMS** tab.

If you issue this command but do not specify ON or OFF, SAS displays the current autosave setting.

See Also
- “Miscellaneous Resources in UNIX Environments” on page 234
- “Modifying the DMS Settings” on page 191

---

**SETDMSFONT Command: UNIX**

Specifies a windowing environment font for the current session.

**Category:** SAS Windowing Environment

**Restriction:** This command is not included in SAS Viya.

**UNIX specifics:** all

**Syntax**

```
SETDMSFONT "font-specification"
```

**Required Argument**

`font-specification`

specifies an X Logical Font Description (XLFD) pattern that you want SAS to use in order to determine the windowing environment font.

**Details**

Most fonts in the X Window System are associated with an XLFD, which contains a number of different fields that are delimited by a hyphen (-) character. The fields in the XLFD indicate properties such as the font family name, weight, size, resolution, and whether the font is proportional or monospaced. See your X Window system documentation for more information about the XLFD and font names that are used with the X Window System.

See Also

**Commands:**
- “DLGFONT Command: UNIX” on page 254

---

**SETENV Command: UNIX**

Defines an environment variable and assigns a value to it.
Syntax

SETENV <variable-name> <variable-value>

UNSETENV variable-name

Required Argument

variable-name

specifies a UNIX environment variable that you can set. This value is required when you use the UNSETENV command.

Optional Argument

variable-value

specifies the value of a UNIX environment variable.

Details

The SETENV command can be used to define an environment variable and assign a value to it. The value of an environment variable can be retrieved from within the SAS session using the SYSGET function during autoexec processing. The command x setenv a/tmp; sets a=/tmp. The command x echo $a; results in the value /tmp.

The UNSETENV command removes an environment variable. The memory for the entry and the environment variable is released.

TOOLCLOSE Command: UNIX

Closes the toolbox.

Category: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.

UNIX specifics: all

Syntax

TOOLCLOSE

Details

The TOOLCLOSE command closes the toolbox.
TOOLEEDIT Command: UNIX

Opens the Tool Editor on the specified toolbox.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

TOOLEEDIT <library.catalog.entry>

Details

If you do not specify an entry name, the Tool Editor edits the toolbox for the active window.

TOOLLARGE Command: UNIX

Toggles the size of the SAS ToolBox window.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

TOOLLARGE <ON | OFF>

Required Arguments

ON
sets the size of the icons in the SAS ToolBox to 48x48.

OFF
sets the size of the icons in the SAS ToolBox to 24x24.

See Also

Commands:

- “TOOLLOAD Command: UNIX” on page 268
Details

If you do not specify ON or OFF, the TOOLLARGE command toggles the size of the SAS ToolBox. The size of the SAS ToolBox changes for your current session only; the new size is not saved.

You can also use the menu to change the size of the SAS ToolBox through the Preferences dialog box. Select Tools » Options » Preferences. Select the ToolBox tab, and then select Use large tools. If you change the size of the SAS ToolBox through the Preferences dialog box, the new size is saved, and SAS displays the large toolbox in subsequent sessions.

TOOLLOAD Command: UNIX

Loads a specific toolbox.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

TOOLLOAD <library.catalog.entry>

Details

If you do not specify an entry name, TOOLLOAD loads the toolbox for the active window.

See Also

Commands:

- “TOOLCLOSE Command: UNIX” on page 266

TOOLTIPS Command: UNIX

Toggles the ToolTip text for an icon in the toolbox.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

TOOLTIPS <ON | OFF>
Required Arguments

**ON**
specifies that the ToolTip text is displayed when you move the cursor over an icon in the toolbox.

**OFF**
specifies that the ToolTip text is not displayed.

Details

If you do not specify ON or OFF, the TOOLTIPS command turns the ToolTip text on or off, depending on the current setting.

You can also use the Preferences dialog box to specify whether ToolTip text is displayed by selecting **Tools** ‒ **Options** ‒ **Preferences**. Select the **ToolBox** tab, and then select **Use tip text**.

See Also

"Changing the Attributes of an Existing Tool" on page 204

---

**WBROWSE Command: UNIX**

Opens a World Wide Web (WWW) browser.

**Category:** SAS Windowing Environment

**Restriction:** This command is not included in SAS Viya.

**UNIX specifics:** all

**Syntax**

```
WBROWSE <"url">
```

**Details**

WBROWSE invokes the web browser that is specified by the resource **SAS.helpBrowser**. If you specify a URL, the document that the URL identifies is automatically displayed. If you do not specify a URL, the SAS home page is displayed.

See Also

"Miscellaneous Resources in UNIX Environments" on page 234

---

**WCOPY Command: UNIX**

Copies the marked contents of the active window to the default buffer.
WCOPY Command: SAS Windowing Environment

Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax
WCOPY

Details
In SAS Windowing Environment, this command executes the STORE command. For more information, see SAS Help and Documentation.

WCUT Command: UNIX

Moves the marked contents of the active window to the default buffer.

Syntax
WCUT

Details
In SAS Windowing Environment, this command executes the CUT command. This command is valid only when the active window is a text editor window, such as Program Editor or Notepad. For information about the CUT command, see online SAS Help and Documentation.

WDEF Command: UNIX

Redefines the active window.

Syntax
WDEF starting-row starting-column number-rows number-columns
Details

The WDEF command operates in the application workspace assigned to the SAS session. The WDEF command does not operate in the AWS container window, except when the container window needs to be enlarged so that you can view a SAS window contained in it. AWS resize behavior is controlled by the SAS.awsResizePolicy resource.

See Also

- “Miscellaneous Resources in UNIX Environments” on page 234
- “X Window Managers” on page 159

WPASTE Command: UNIX

Pastes the contents of the default buffer into the active window.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

WPASTE

Details

In SAS Windowing Environment, this command executes the PASTE command. For information about the PASTE and command, see online SAS Help and Documentation.

WUNDO Command: UNIX

Undoes one line of text entry, or undoes the last cut, copy, or paste action.

Category: SAS Windowing Environment
Restriction: This command is not included in SAS Viya.
UNIX specifics: all

Syntax

WUNDO
Details
In SAS Windowing Environment, this command executes the UNDO command. In SAS/GRAPH windows, WUNDO is invalid.

One execution of the WUNDO command undoes text entry for only one line at a time. If you issue the WUNDO command again, the previous line of text is undone.

If you use the CC command to copy and paste a block of text, and then issue the WUNDO command, the block of text that you copied is deleted. If you use the DD command to delete a block of text, and then issue the WUNDO command, the block of text that you deleted is restored.

---

Note: The WUNDO command cannot replace lines that the SUBMIT command removes. It cannot reverse the effects of submitted SAS statements.

---

X Command: UNIX

Enables you to enter UNIX commands without ending the SAS session.

Categories: Environment
CAS
UNIX specifics: all

Syntax
X \textit{command}
X '{\textit{command-1}; \textit{command-2}...<; \textit{command-n}}'

Required Argument
\textit{command}
specifies a UNIX command.

Details
When you enter the X command, SAS starts a shell to execute the commands that you specified. The commands that you enter are processed differently, depending on whether you enter one command or more than one command.

See Also
“Executing Operating System Commands from Your SAS Session” on page 17

XSYNC Command: UNIX

Changes X synchronization during a SAS session.
Syntax

\texttt{XSYNC \langle ON | OFF \rangle}

Details

This command turns off the buffering that is normally done by the X Window System. X synchronization is off by default. Turning it on is useful when you are debugging applications, although it drastically reduces performance.

If you do not specify ON or OFF, XSYNC toggles the synchronization. The XSYNC command is valid from any SAS window.
Data Set Options under UNIX

This section describes SAS data set options that exist only in the UNIX environment, as well as options whose behavior or syntax is specific to UNIX. Each data set option description includes a brief “UNIX specifics” section that explains which aspect of the data set option is specific to UNIX. For data set options that have behavior or syntax specific to UNIX, see SAS Data Set Options: Reference for a complete description of the option.

Specify data set options following the data set name in SAS statements as follows:

...data-set-name(option-1=value-1 option-2=value-2, ...)

A few data set options are also SAS system options (for example, BUFSIZE=). If the same option is specified both as a system option and as a data set option, SAS uses the value given with the data set option. For more information about SAS system options, see “Customizing Your SAS Session By Using System Options” on page 21 and “SAS System Options under UNIX” on page 376.

To view a table of all of the data set options available under UNIX, see “Summary of SAS Data Set Options in UNIX Environments” on page 276.
# Summary of SAS Data Set Options in UNIX Environments

SAS data set options are listed in the following table. The table lists the name of each option, a brief description, whether the option can be used for a data set opened for input, output, or update, and a list of engines for which the option is valid. The See column tells you where to look for more information about an option. Use the following legend to locate the additional information.

- **COMP**
  - See the description of the data set option in this section.

- **DS**
  - See *SAS Data Set Options: Reference*.

- **NLS**

<tr>
<td>WRITE=</td>
<td>assigns a WRITE password to a SAS data set and enables access to a Write-protected SAS file.</td>
<td>output, update</td>
<td>V9, V8, V6</td>
<td>DS</td>
</tr>
</tbody>
</table>

1 The TOBSNO= option is valid only for data sets that are accessed through a SAS server from the REMOTE engine.

## Dictionary

### ALTER= Data Set Option: UNIX

Specifies a password for a SAS file that prevents users from replacing or deleting the file, but permits Read and Write access.

Valid in: DATA step and PROC steps  
Category: Data Set Control  
Default: none  
Restriction: This data set option is not valid in a DATA step that runs on CAS.  
Engine: V9, V8, V6  
See: “ALTER= Data Set Option” in SAS Data Set Options: Reference

### Syntax

```
ALTER=alter-password
```
Required Argument

*alter-password*

Details

The ALTERT= option applies to all types of SAS files except catalogs. You can use this option to assign an *alter-password* to a SAS file or to access a Read-protected, Write-protected, or Alter-protected SAS file.

---

**BUFNO= Data Set Option: UNIX**

Specifies the number of buffers to be allocated for processing a SAS data set.

- **Valid in:** DATA step and PROC steps
- **Category:** Data Set Control
- **Default:** 1
- **Restriction:** This data set option is not valid in a DATA step that runs on CAS.
- **Engine:** V9, V8, V6
- **UNIX specifics:** default value
- **See:** “BUFNO= Data Set Option” in SAS Data Set Options: Reference

**Syntax**

```
BUFNO=n | nK | hexX | MIN | MAX
```

**Required Arguments**

- **n | nK**
  
specifies the number of buffers in multiples of 1 (bytes); 1,024 (kilobytes). For example, a value of 8 specifies 8 buffers, and a value of 1k specifies 1024 buffers.

- **hexX**
  
specifies the number of buffers as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the value 2dx specifies 45 buffers.

- **MIN**
  
sets the minimum number of buffers to 0, which causes SAS to use the minimum optimal value for the operating environment.

- **MAX**
  
sets the number of buffers to the maximum possible number in your operating environment, up to the largest four-byte signed integer, which is $2^{31} - 1$, or approximately 2 billion.
Details
The buffer number is not a permanent attribute of the data set; it is valid only for the current SAS step. BUFNO= applies to SAS data sets that are opened for input, output, or update.

See Also

Data Set Options:
- “BUFSIZE= Data Set Option: UNIX” on page 281

System Options:
- “BUFNO System Option: UNIX” on page 386

**BUFSIZE= Data Set Option: UNIX**

Specifies the size of a permanent buffer page for an output SAS data set.

Valid in: DATA step and PROC steps
Category: Data Set Control
Default: 0
Restriction: This data set option is not valid in a DATA step that runs on CAS.
Engine: V9, V8
UNIX specifics: valid range
See: “BUFSIZE= Data Set Option” in SAS Data Set Options: Reference

Syntax

**BUFSIZE=** \( n \mid nK \mid nM \mid nG \mid hexX \mid MAX \)

Required Arguments

\( n \mid nK \mid nM \mid nG \)

specifies the buffer size in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). For example, a value of 8 specifies 8 bytes, and a value of 3M specifies 3,145,728 bytes.

The buffer size can range from 1K to 2G–1. For values greater than 1G, use the \( nM \) option.

\( hexX \)

specifies the page size as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx sets the page size to 45 bytes.
MAX

sets the buffer page size to the maximum possible number in your operating environment, up to the largest four-byte, signed integer, which is $2^{31} - 1$, or approximately 2 billion bytes.

Details

The BUFSIZE= data set option specifies the buffer size for data sets that you are creating. This option is valid only for output data sets.

If you use the default value (0) when you create a SAS data set, the engine calculates a buffer size to optimize CPU and I/O use. This size is the smallest multiple of 8K that can hold 80 observations, but is not larger than 64K.

If you specify a nonzero value when you create a SAS data set, the engine uses that value. If that value cannot hold at least one observation or is not a valid buffer size, the engine rounds the value up to a multiple of 1K.

See Also

System Options:

- “BUFSIZE System Option: UNIX” on page 388

---

**PW= Data Set Option: UNIX**

Assigns a READ, WRITE, or ALTER password to a SAS file, and enables access to a password-protected SAS file.

**Valid in:** DATA step and PROC steps

**Category:** Data Set Control

**Default:** none

**Restriction:** This data set option is not valid in a DATA step that runs on CAS.

**Engine:** V9, V8, V6

**See:** “PW= Data Set Option” in SAS Data Set Options: Reference

**Syntax**

```
PW=password
```

**Required Argument**

**password**

Details
The PW= option applies to all types of SAS files except catalogs. You can use this option to assign a password to a SAS file or to access a password-protected SAS file.

USEDIRECTIO= Data Set Option: UNIX

Turns on direct file I/O for a library that contains the file to which the ENABLEDIRECTIO option has been applied.

Valid in:
DATA step
Category:
Data Set Control
Default:
Off
Restriction:
This data set option is not valid in a DATA step that runs on CAS.
Engine:
V9, V8
UNIX specifics:
To use this option, you must also use the ENABLEDIRECTIO option in the LIBNAME statement where the libref was assigned.

Syntax
USEDIRECTIO= YES | NO

Required Argument
YES | NO
specifies whether to turn on the USEDIRECTIO= option.

Details
The USEDIRECTIO= data set option turns on direct file I/O for a data set that is listed in a DATA statement. The associated libref must have been defined with the ENABLEDIRECTIO option in the LIBNAME statement.

Using ENABLEDIRECTIO in a LIBNAME statement makes direct file I/O possible for data sets in that library. Direct I/O itself is not turned on. You must use the USEDIRECTIO= option to produce direct file I/O.

You can turn on direct file I/O in two ways:

- Use both the ENABLEDIRECTIO and USEDIRECTIO= options in the LIBNAME statement:

```
libname libref-name '.' ENABLEDIRECTIO USEDIRECTIO=yes;
```

In this case, SAS uses direct file I/O on all SAS I/O data sets that are opened using the libref libref-name.

- Use ENABLEDIRECTIO in the LIBNAME statement and use USEDIRECTIO= in a DATA statement:

```
libname libref-name '.' ENABLEDIRECTIO;
data libref-name.data-set-name (USEDIRECTIO=yes);
```
In this case, `libref-name.data-set-name` is opened for direct file I/O. Other SAS I/O data sets referenced by `libref-name` will not use direct file I/O.

`USEDIRECTIO=` by itself has no effect. Neither of the following statements open a data set for direct file I/O:

```sas
libname libref-name '.' USEDIRECTIO=yes;
data libref-name.data-set-name (USEDIRECTIO=yes);
```

**Example**

The following example uses the ENABLEDIRECTIO LIBNAME option to enable files that are associated with the libref `test` to be opened for direct I/O. The `USEDIRECTIO=` data set option opens `test.file1` for direct I/O. `test.file2` is not opened for direct I/O.

```sas
LIBNAME test '.' ENABLEDIRECTIO;
data test.file1 (USEDIRECTIO=yes);
   ... more SAS statements ...
run;
data test.file2;
   ... more SAS statements ...
run;
```

**See Also**

**Statements:**

- "LIBNAME Statement: UNIX" on page 359
Defining Environment Variables in UNIX Environments

What Is a UNIX Environment Variable?

UNIX environment variables are variables that apply to both the current shell and to any subshells that it creates (for example, when you send a job to the background or execute a script). If you change the value of an environment variable, the change is passed forward to subsequent shells, but not backward to the parent shell.

In a SAS session, you can use the SASV9_OPTIONS environment variable to specify system options and the SASV9_CONFIG environment variable to specify a configuration file. Any changes that you make to an environment variable after initialization of a SAS session are not recognized.

You can also use environment variables as filerefs and librefs in various statements and commands. Filerefs and librefs consist of uppercase letters, digits, and the underscore character in environment variable names. Other characters are not recognized by SAS. For more information, see "Using Environment Variables as Filerefs in UNIX Environments" on page 65 or "Using Environment Variables to Assign Filerefs in UNIX Environments" on page 90.
Note: A SAS/ACCESS product initializes the environment variables that it needs when loading. For more information, see the documentation for your SAS/ACCESS product.

How to Define an Environment Variable for Your Shell

Defining Environmental Variables

The way in which you define an environment variable depends on the shell that you are running. (To determine which shell you are running, type `ps` at the command prompt or `echo $SHELL` to see the current value of the SHELL environment variable.)

Bourne and Korn Shells

In the Bourne shell and in the Korn shell, use the `export` command to export one or more variables to the environment. For example, these commands make the value of the variable `scname` available to all subsequent shell scripts:

```bash
$ scname=phonelist
$ export scname
```

In the Korn shell, you can combine these commands into one command:

```bash
$ export scname=phonelist
```

If you change the value of `scname`, then the new value affects both the shell variable and the environment variable. If you do not export a variable, only the shell script in which you define has access to its value.

C Shell

In the C shell (csh and tcsh), you set (define and export) environment variables with the `setenv` (set environment) command. For example, this command is equivalent to the commands shown previously:

```bash
% setenv scname phonelist
```

Use the OPTIONS Statement and SET System Option

You can use the SET system option to set environment variables during a SAS session. However, you cannot use this option to set environment variables that are checked during SAS start-up. Here is an example that sets the LUA_PATH environment variable:

```sas
options set=LUA_PATH="/usr/local/lua/?.lua";
```
Displaying the Value of an Environment Variable

To display the values of individual environment variables, use the `echo` command and parameter substitution. An example is `echo $SHELL`, which returns the current value of the `SHELL` environment variable. Use the `env` (or `printenv`) command to display all environment variables and their current values.

Dictionary

**AUTHINFO Environment Variable**

Specifies the location of the file in which a user ID and password are kept for authentication, typically called the authinfo file.

**Categories:**
- Environment Control
- CAS

**Default:** None

**Restriction:** This environment variable is used to authenticate to the CAS server only.

**Details**

Use the AUTHINFO environment variable to specify the location of the authinfo file on your system. This variable can be set to the location of one or more files. Use a semicolon to separate multiple filenames. Set the value of the AUTHINFO environment variable using the instructions in “How to Define an Environment Variable for Your Shell” on page 286.

The value that you specify typically includes the path and filename for the authinfo file on your system. For example, when working in a C shell, you might specify the AUTHINFO environment variable as follows:

```
setenv authinfo '$HOME/authInfo-file'
```

If the `AUTHINFO=` system option is set in a program that you run in batch mode, the system option value overrides the value that is set for the AUTHINFO= environment variable.

For more information, see “Authinfo File Requirement” in SAS Viya: System Programming Guide.

**PATHENCODING Environment Variable: UNIX**

Specifies the encoding for external file references and directory references when the encoding is different from the SAS session encoding.
The characters in a pathname must contain characters that are recognized by both the session encoding and the encoding that is specified by PATHENCODING.

UNIX specifics: 

Details

Set the value of the PATHENCODING environment variable using the instructions in "How to Define an Environment Variable for Your Shell" on page 286.

The encoding value that you assign specifies the encoding for external file references and directory references that are accessed from within a SAS program. Specify a value for this environment variable when external file encoding and directory encoding are different from the SAS session encoding. SAS uses the default session encoding when referencing external files and directories. The PATHENCODING environment variable provides an alternative encoding for external file and directory references. PATHENCODING is valid only for files that are located on disk. When the PATHENCODING environment variable has a valid encoding value, SAS transcodes the pathname from the SAS session encoding into the specified encoding.

For a list of valid encoding values on UNIX, see “UNIX Encoding Values” in SAS National Language Support (NLS): Reference Guide.

The pathnames that you specify within a SAS program must be entered in the SAS session encoding. Do not specify pathnames in the encoding that you specify for the PATHENCODING environment variable.

In SAS 9.4M2, to specify a PATHENCODING value of UTF-8 in a SAS session that uses English, the characters in a pathname must contain characters that are recognized by both the session encoding and the encoding that is specified by PATHENCODING. As a result, to specify a PATHENCODING value of UTF-8 in a SAS session that uses English (LANG=EN), you must specify a SAS session encoding of UTF-8 or SAS_U8.

---

SASV9_CONFIG Environment Variable: UNIX

Specifies the configuration file that is referenced when you start a SAS session.

Details

Set the value of the SASV9_CONFIG environment variable using the instructions in “How to Define an Environment Variable for Your Shell” on page 286.
The file specification that you assign to SASV9_CONFIG specifies the path and name of the configuration file that the SAS session uses. This configuration file contains all of the SAS system options that you want to use in a SAS session. For example, in a Korn shell, you might assign the custom.cfg file in your home directory to SASV9_CONFIG as follows:

```bash
> export sasv9_config=/u/<user_id>/custom.cfg
```

**SASV9_OPTIONS Environment Variable: UNIX**

Specifies the list of SAS system options that are automatically used when you start a SAS session.

**Categories:** Environment Control, CAS

**Default:** None

**UNIX specifics:** All

**Details**

Use the SASV9_OPTIONS environment variable to specify a list of SAS system options that are automatically used when you start a SAS session. This is useful if you typically set the same SAS system options each time you work with SAS.
This section describes SAS formats that have behavior or syntax that is specific to UNIX environments. Each format description includes a brief "UNIX specifics" section that explains which aspect of the data set option is specific to UNIX. Each format is described in this documentation and in SAS Formats and Informats: Reference.

Be aware that names for user-defined formats cannot end in a number. For more information, see “User-Defined Formats” in SAS Formats and Informats: Reference and “Names in the SAS Language” in SAS Language Reference: Concepts.

### Dictionary

#### HEX Format: UNIX

Converts real binary (floating-point) numbers to hexadecimal representation.

- **Categories:** Numeric, CAS
- **Alignment:** Left
- **UNIX specifics:** Floating-point representation
See: “HEXw. Format” in SAS Formats and Informats: Reference

Syntax

HEXw.

Syntax Description

w specifies the width of the output field.

Default 8

Range 1–16

Tip If w < 16, the HEXw. format converts real binary numbers to fixed-point integers before writing them as hexadecimal characters. It also writes negative numbers in two’s complement notation, and right aligns digits. If w is 16, HEXw. displays floating-point values in their hexadecimal form.

Details

The HEXw. format converts a real (floating-point) binary number to its hexadecimal representation. When you specify a width value of 1 through 15, the real binary number is truncated to a fixed-point integer before being converted to a hexadecimal number. When you specify 16 for the width, SAS writes the floating-point value of the number, but does not truncate it.

Note: UNIX systems vary widely in their floating-point representation. For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.

$HEX Format: UNIX

Converts character values to hexadecimal representation.

Categories: Character
CAS

Alignment: Left

UNIX specifics: Produces ASCII codes

See: “$HEXw. Format” in SAS Formats and Informats: Reference

Syntax

$HEXw.
**Syntax Description**

\[ w \]

specifies the width of the output field.

**Default**

2

**Range**

1–32767

**Details**

Under UNIX, the $HEXw.$ format produces hexadecimal representations of ASCII codes for characters. Each byte requires two columns. Therefore, you need twice as many columns to print a value with the $HEXw.$ format.

---

**IB Format: UNIX**

Writes integer binary (fixed-point) values.

**Category:** Numeric

**Alignment:** Left

**Restriction:** This format is not supported on the CAS server.

**UNIX specifics:** Byte order

**See:** “IBw.d Format” in SAS Formats and Informats: Reference

---

**Syntax**

**IB\( w.d \)**

**Syntax Description**

\[ w \]

specifies the width of the output field.

**Default**

4

**Range**

1–8

\[ d \]

specifies to multiply the number of \(10^d\). This argument is optional.

**Default**

0

**Range**

0–10

**Details**

The IB\( w.d \) format writes integer binary (fixed-point) values. Integers are stored in integer-binary, or fixed-point, form. For example, the number 2 is stored as 00000002. If the format includes a \(d\) value, the data value is multiplied by \(10^d\).
PD Format: UNIX

Writes data in packed decimal format.

Category: Numeric
Alignment: Left
Restriction: This format is not supported on the CAS server.
UNIX specifics: Data representation
See: “PDw.d Format” in SAS Formats and Informats: Reference

Syntax

**PDw.d**

Syntax Description

**w**
specifies the width of the output field. The **w** value specifies the number of bytes, not the number of digits. (In packed decimal data, each byte contains two digits.)

Default 1
Range 1–16

**d**
specifies to multiply the number by 10^**d**. This argument is optional.

Default 0
Range 0–31

Details

The **PDw.d** format writes values in packed decimal format. In packed decimal data, each byte contains two digits. The **w** value represents the number of bytes, not the number of digits. The value's sign is the first byte. Because the entire first byte is used for the sign, you should specify at least a width of 2.

The **PDw.d** format writes missing numerical data as –0. When the **PDw.d** informat reads a value of –0, the result is a value of 0.

For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.
PIB Format: UNIX

Writes positive integer binary (fixed-point) values.

Category: Numeric
Alignment: Left
Restriction: This format is not supported on the CAS server.
UNIX specifics: byte order
See: “PIBw.d Format” in SAS Formats and Informats: Reference

Syntax

PIBw.d

Syntax Description

w
specifies the width of the output field.

Default 1
Range 1–8

d
specifies to multiply the number by 10^d. This argument is optional.

Default 0
Range 0–10

Details

The PIBw.d format writes fixed-point binary values, treating all values as positive. Thus, the high-order bit is part of the value, rather than the value's sign. If a d value is specified, the data value is multiplied by 10^d.

For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.

RB Format: UNIX

Writes real binary (floating-point) data in real binary format.

Category: Numeric
Alignment: Left
Restriction: This format is not supported on the CAS server.
UNIX specifics: floating-point representation
See: “RBw.d Format” in SAS Formats and Informats: Reference

### Syntax

**RBw.d**

### Syntax Description

- **w**
  - Specifies the width of the output field.
  - Default: 4
  - Range: 2–8

- **d**
  - Specifies to multiply the number by 10^d. This argument is optional.
  - Default: 0
  - Range: 0–10

### Details

The RBw.d format writes numeric data in real binary (floating-point) notation. SAS stores all numeric values in floating-point.

Real binary is the most efficient format for representing numeric values because SAS already represents numbers this way and no conversion is needed.

For more information, see “RB Informat: UNIX” on page 331 and “Reading and Writing Binary Data in UNIX Environments” on page 244.

---

### ZD Format: UNIX

Writes numeric data in zoned decimal format.

**Category:** Numeric

**Alignment:** Left

**Restriction:** This format is not supported on the CAS server.

**UNIX specifics:** Data representation

See: “ZDw.d Format” in SAS Formats and Informats: Reference

### Syntax

**ZDw.d**
Syntax Description

\textit{w}  
specifies the width of the output field.

- Default: 1
- Range: 1–32

\textit{d}  
specifies to multiply the number by \(10^d\). This argument is optional.

- Default: 0
- Range: 0–31

Details

The ZD\textit{w.d} format writes zoned decimal data. This format is also known as overprint trailing numeric format. Under UNIX, the last byte of the field includes the sign with the last digit. The conversion table for the last byte is as follows:

**Table 15.1 Conversion Table**

<table>
<thead>
<tr>
<th>Digit</th>
<th>ASCII Character</th>
<th>Digit</th>
<th>ASCII Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>{</td>
<td>–0</td>
<td>}</td>
</tr>
<tr>
<td>1</td>
<td>A</td>
<td>–1</td>
<td>J</td>
</tr>
<tr>

</tbody>
</table>

For more information, see “ZD Informat: UNIX” on page 333 and “Reading and Writing Binary Data in UNIX Environments” on page 244.
Functions and CALL Routines under UNIX

This section describes SAS functions and CALL routines whose behavior is specific to UNIX environments. Each function and CALL routine description includes a brief "UNIX specifics" section that explains which aspect of the function and CALL routine is specific to UNIX. For more information about all of these functions and CALL routines, see SAS Functions and CALL Routines: Reference.
Dictionary

BYTE Function: UNIX

Returns one character in the ASCII collating sequence.

Categories:
Character
CAS

UNIX specifics:
Uses the ASCII collating sequence

See:
“BYTE Function” in SAS Functions and CALL Routines: Reference

Syntax

BYTE(n)

Required Argument

n
specifies an integer that represents a specific ASCII character. The value of n can range from 0 to 255.

Details

If the BYTE function returns a value to a variable that has not yet been assigned a length, by default the variable is assigned a length of 1.

CALL MODULE Routine: UNIX

Calls a specific routine or module that resides in a shared executable library.

Category:
External Files

Restriction:
This function is not supported on the CAS server.

Interaction:
When a SAS server is in a locked-down state, the CALL MODULE routine does not execute. For more information, see “SAS Processing Restrictions for Servers in a Locked-Down State” in SAS Language Reference: Concepts.

UNIX specifics:
All

See:
“CALL MODULE Routine” in SAS Functions and CALL Routines: Reference

Syntax

CALL MODULE(<control>, module, argument-1, argument-2 ..., argument-n);
**CALL MODULE Routine: UNIX**

`number=MODULEN(<control>, module, argument-1, argument-2 ..., argument-n);`

`character=MODULEC(<control>, module, argument-1 ..., argument-2, argument-n);`

**CALL MODULEI(<control>, module, argument-1, argument-2 ..., argument-n);**

`number=MODULEIN(<control>, module, argument-1, argument-2 ..., argument-n);`

`character=MODULEIC(<control>, module, argument-1, argument-2 ..., argument-n);`

**Required Arguments**

*module*

specifies the name of the external module to use. The *module* can be specified as a shared library with the routine name or ordinal value, separated by a comma. You do not need to specify the shared library name if you specified the MODULE attribute for the routine in the SASCBTBL attribute table. This is true as long as the routine name is unique (that is, no other routine has the same name in the attribute file). For more information, see “The SASCBTBL Attribute Table” on page 123.

The module must reside in a shared library, and the module must be able to be called externally. The shared library name is not case sensitive. However, the routine name is based on the restraints of the routine’s implementation language, so the routine name is case sensitive.

If the shared library supports ordinal-value naming, you can provide the shared library name followed by a decimal number, such as 'XYZ,30'.

You can specify *module* as a SAS character expression instead of as a constant.

*argument-1, argument-2, ..., argument-n*

specifies the arguments to pass to the requested routine. Use the proper attributes for the arguments (that is, numeric arguments for numeric attributes and character arguments for character attributes).

**CAUTION**

Be sure to use the correct arguments and attributes. If you use incorrect arguments or attributes for a shared library function, you can cause SAS to crash or you might see unexpected results.

**Optional Argument**

*control*

is an optional control string whose first character must be an asterisk (*), followed by any combination of the following characters:

- **I** prints the hexadecimal representations of all arguments to the MODULE function and to the requested shared library routine before and after the shared library routine is called. You can use this option to help diagnose problems that are caused by incorrect arguments or attribute tables. If you specify the I option, the E option is implied.

- **E** prints detailed error messages. Without the E option (or the I option, which supersedes it), the only error message that the MODULE function generates is "Invalid argument to function." This is usually not enough information to determine the cause of the error.
Sx uses x as a separator character to separate field definitions. You can then specify x in the argument list as its own character argument to serve as a delimiter for a list of arguments that you want to group together as a single structure. Use this option only if you do not supply an entry in the SASCBTBL attribute table. If you do supply an entry for this module in the SASCBTBL attribute table, you should use the FDSTART option in the ARG statement in the table to separate structure definitions.

H provides brief help information about the syntax of the MODULE routines, the attribute file format, and the suggested SAS formats and informats.

For example, the control string "**IS/" specifies that parameter lists be printed and that the string '/' is to be treated as a separator character in the argument list.

Details

The following functions permit vector and matrix arguments. You can use them only within the IML procedure:

- CALL MODULEI
- MODULEIN
- MODULEIC

For more information, see the SAS/IML Studio: User’s Guide.

The MODULE functions execute a routine module that resides in an external (outside SAS) shared library with the specified arguments argument-1 through argument-n.

The CALL MODULE routine does not return a value. The MODULEN and MODULEC functions return a number or a character value, respectively. Which routine you use depends on the expected return value of the shared library function that you want to execute.

MODULEI, MODULEIC, and MODULEIN are special versions of the MODULE functions that permit vector and matrix arguments. Their return values are still scalar. You can invoke these functions only from PROC IML.

Other than this name difference, the syntax for all six routines is the same.

The MODULE function builds a parameter list by using the information in argument-1 to argument-n and by using a routine description and argument attribute table that you define in a separate file. Before you invoke the MODULE routine, you must define the fileref of SASCBTBL to point to this external file. You can name the file whatever you want when you create it.

If you define this table, then you can use SAS variables and formats as arguments in the MODULE function. In this way, you ensure that these arguments are properly converted before being passed to the shared library routine.

**CAUTION**

Using the MODULE function without defining an attribute table can cause SAS to crash, produce unexpected results, or result in severe errors. You need to use an attribute table for all external functions that you want to invoke.
CALL SLEEP Routine: UNIX

For a specified period of time, suspends the execution of a program that invokes this CALL routine.

**Syntax**

CALL SLEEP(\(n <, \text{unit}\));

**Required Argument**

\(n\) is a numeric constant that specifies the number of units of time for which you want to suspend execution of a program.

**Optional Argument**

\(\text{unit}\) specifies the unit of time in seconds, which is applied to \(n\). For example, 1 corresponds to 1 second, .001 corresponds to 1 millisecond, and 5 corresponds to 5 seconds.

_DEFAULT_.001

**Details**

CALL SLEEP puts the DATA step in which it is invoked into a nonactive wait state, using no CPU time and performing no input or output. If you are running multiple SAS processes, each process can execute CALL SLEEP independently without affecting the other processes.

**Note:** Extended sleep periods can trigger automatic host session termination based on time-out values set at your site. Contact your host system administrator to determine the time-out values that are used at your site.
CALL SYSTEM Routine: UNIX

Submits an operating environment command for execution.

Category: Special
Restriction: This function is not supported on the CAS server.
UNIX specifics: Command must evaluate to a valid UNIX command
See: “CALL SYSTEM Routine” in SAS Functions and CALL Routines: Reference

Syntax

CALL SYSTEM(command);

Required Argument

command specifies any of the following:

- a UNIX command enclosed in quotation marks
- an expression whose value is a UNIX command
- the name of a character variable whose value is a UNIX command

Details

The CALL SYSTEM routine issues operating system commands. The output of the command appears in the window from which you invoked SAS.

The value of the XSYNC system option affects how the CALL SYSTEM routine works.

Note: The CALL SYSTEM routine can be executed within a DATA step. However, neither the X statement nor the %SYSEXEC macro program statement is intended for use during the execution of a DATA step.

In the following example, for each record in answer.week, if the resp variable is y, the CALL SYSTEM routine mails a message:

```sas
data _null_;  
set answer.week;  
if resp='y' then  
do;  
call system('mail mgr < $HOME/msg');  
end;  
run;
```

See Also

“Executing Operating System Commands from Your SAS Session” on page 17
COLLATE Function: UNIX

Returns a character string in an ASCII collating sequence.

Categories:  Character
            CAS

UNIX specifics:  Uses ASCII collating sequence

See:  “COLLATE Function” in SAS Functions and CALL Routines: Reference

Syntax

COLLATE(start-position <, end-position>) | (start-position <, , length>)

Required Argument

start-position

specifies the numeric position in the collating sequence of the first character to be returned.

Optional Arguments

end-position

specifies the numeric position in the collating sequence of the last character to be returned.

length

specifies the number of characters in the collating sequence.

Details

The COLLATE function returns a string of ASCII characters. The ASCII collating sequence contains 256 positions, referenced with the numbers 0 through 255. Characters above 127 correspond to characters used in European languages as defined in the ISO 8859 character set.

Unless you assign the return value of the COLLATE function to a variable with a defined length less than 200, the ASCII collating sequence string is padded with spaces to a length of 200. If the ASCII collating sequence is greater than 200 characters, you must specify the length for the return string in a LENGTH statement. Otherwise, the returned string is truncated to a length of 200 characters. For more information, see the following examples.

Examples:

Example 1: Truncating the Variable Length to 200 Characters

Because the following code does not include a LENGTH statement, the length attribute for the ADDRESS variable is truncated to 200 characters:

data sales;
Because length of ADDRESS is limited to 200 characters, the returned string from the COLLATE function is limited to 200 characters.

Example 2: Specifying a Length Greater Than 200 Characters

To specify a length greater than 200 characters for a specific variable, you can use the LENGTH statement. In the following code, the length of ADDRESS is specified as 240 characters:

```plaintext
data sales;
  length Address $240;
  Address=collate(1, 241);
run;
proc contents;
run;
```

Because the length of ADDRESS is set to 240 characters, the returned string from the COLLATE function contains 240 characters.

See Also

**Statements:**

- "LENGTH Statement: UNIX" on page 359

---

**DINFO Function: UNIX**

Returns information about a directory.

**Category:** External Files

**Restriction:** This function is not supported on the CAS server.

**UNIX specifics:** Directory pathname, owner, group, permissions, and the time last modified information items are available
Syntax

DINFO(directory-id, information-item)

Required Arguments

directory-id

is a numeric variable that specifies the identifier that was assigned when the
directory was opened by the DOPEN function.

information-item

is a character constant, variable, or expression that specifies the information
item to be retrieved. DINFO returns a blank if the value of the information-item
argument is invalid. The information available varies according to the operating
environment.

Details

Directories that are opened with the DOPEN function are identified by a directory-id
value. Use the DOPTNAME function to determine the names of the available
system-dependent directory information items. Use the DOPTNUM function to
determine the number of directory information items that are available.

If directory-id points to a list of concatenated directories, then the directory is the list
of concatenated directory names.

The information items that are available include directory pathname (the pathname
of the directory-id), owner, group, permissions, and the time last modified.

Examples:

Example 1: Using DINFO to Return Information about a Directory

This example opens the directory MYDIR, determines the number of directory
information items available, and retrieves the value of the last one:

```plaintext
%let filrf=MYDIR;
%let rc=%sysfunc(filename(filrf, "physical-name"));
%let did=%sysfunc(dopen(&filrf));
%let numopts=%sysfunc(doptnum(&did));
%let foption=%sysfunc(doptname(&did, &numopts));
%let charval=%sysfunc(dinfo(&did, &foption));
%let rc=%sysfunc(dclose(&did));
```

Example 2: Using DINFO within a DATA Step

This example creates a data set that contains the name and value of each directory
information item:

```plaintext
data diropts;
  length optname $ 32 optval $ 40;
  rc=filename("mydir", "physical-name");
  put "rc = 0 if the directory exists: " rc=;
  did=dopen("mydir");
  numopts=doptnum(did);
  do i=1 to numopts;
    optname=doptname(did, i);
```
The code snippet provided demonstrates how to open a directory and retrieve information about its options. The `dopen` function is used to open the directory, and the `doptname` function is used to retrieve the names of the options. The `dinfo` function is used to get the values of the options.

### Output 16.3 Sample SAS Log

```sas
12  data diropts;
13     length optname $ 32 optval $ 40;
14     rc=filename("mydir", "/u");
15     put "rc = 0 if the directory exists: " rc=;
16     did=dopen("mydir");
17     numopts=doptnum(did);
18     do i=1 to numopts;
19         optname=doptname(did, i);
20         put i= optname=;
21         optval=dinfo(did, foption);
22         put optval=;
23     end;
24  run;
```

RC = 0 if the directory exists: rc=0
i=1 optname=Directory
optval= 

i=2 optname=Owner Name
optval= 

i=3 optname=Group Name
optval= 

i=4 optname=Access Permission
optval= 

i=5 optname=Last Modified
optval=

NOTE: The data set WORK.DIROPTS has 1 observations and 7 variables.
NOTE: DATA statement used (Total process time):
real time 0.07 seconds
cpu time 0.04 seconds

### See Also

- "DOPTNAME Function: UNIX" on page 310
- "DOPTNUM Function: UNIX" on page 311

### DOPEN Function: UNIX

Opens a directory, and returns a directory identifier value.

**Category:** External Files

**Restrictions:** You must associate a fileref with the directory before calling DOPEN.

This function is not supported on the CAS server.

**See:** FILENAME Function: UNIX
Syntax

DOPEN(fileref)

Required Argument

fileref

is a character constant, variable, or expression that specifies the fileref assigned to the directory. In a DATA step, fileref can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the fileref. In macro code, fileref can be any expression.

Details

DOPEN opens a directory and returns a directory identifier value (a number greater than 0) that is used to identify the open directory in other SAS external file access functions. If the directory cannot be opened, DOPEN returns 0, and you can obtain the error message by calling the SYSMSG function. The directory to be opened must be identified by a fileref. You can assign filerefs using the FILENAME statement or the FILENAME external file access function. Under some operating environments, you can also assign filerefs using system commands.

If you call the DOPEN function from a macro, then the result of the call is valid only when the result is passed to functions in a macro. If you call the DOPEN function from the DATA step, then the result is valid only when the result is passed to functions in the same DATA step.

Examples:

Example 1: Using DOPEN to Open a Directory

This example assigns the fileref MYDIR to a directory. It uses DOPEN to open the directory. DOPTNUM determines the number of system-dependent directory information items available, and DCLOSE closes the directory:

```sas
%let filrf=MYDIR;
%let rc=%sysfunc(filename(filrf, physical-name));
%let did=%sysfunc(dopen(&filrf));
%let infocnt=%sysfunc(doptnum(&did));
%let rc=%sysfunc(dclose(&did));
```

Example 2: Using DOPEN within a DATA Step

This example opens a directory for processing within a DATA step.

```sas
data _null_;
  drop rc did;
  rc=filename("mydir", "physical-name");
  did=dopen("mydir");
  if did > 0 then do;
    ...more SAS statements...
  end;
  else do;
```
DOPTNAME Function: UNIX

Returns directory attribute information.

Category: External Files

Restriction: This function is not supported on the CAS server.

UNIX specifics: Directory pathname, owner, group, permissions, and time last modified information items are available

Syntax

```
DOPTNAME(directory-id, nval)
```

Required Arguments

- **directory-id**: is a numeric variable that specifies the identifier that was assigned when the directory was opened by the DOPEN function.

- **nval**: is a numeric constant, variable, or expression that specifies the sequence number of the information item.

Details

The DOPTNAME function returns the name of the specified information item number for a directory that was previously opened with the DOPEN function. If `directory-id` points to a list of concatenated directories, then Directory is the list of concatenated directory names.

The information items that are available include directory pathname (the pathname of the `directory-id`), owner, group, permissions, and the time last modified.

Examples:

Example 1: Using DOPTNAME to Retrieve Directory Attribute Information

This example opens the directory with the fileref MYDIR, retrieves all system-dependent directory information items, writes them to the SAS log, and closes the directory:

```
%let filrf=mydir;
%let rc=%sysfunc(filename(filrf, physical-name));
%let did=%sysfunc(dopen(&filrf));
%let infocnt=%sysfunc(doptnum(&did));
```
%do j=1 %to &infocnt;
  %let opt=%sysfunc(doptname(&did, &j));
  %put Directory information=&opt;
%end;
%let rc=%sysfunc(dclose(&did));

Example 2: Using DOPTNAME within a DATA Step

This example creates a data set that contains the name and value of each directory information item:

data diropts;
  length optname $ 12 optval $ 40;
  keep optname optval;
  rc=filename("mydir", "physical-name");
  did=dopen("mydir");
  numopts=doptnum(did);
  do i=1 to numopts;
    optname=doptname(did, i);
    optval=dinfo(did, optname);
    output;
  end;
run;

DOPTNUM Function: UNIX

Returns the number of information items that are available for a directory.

Category: External Files

Restriction: This function is not supported on the CAS server.

UNIX specifics: Directory pathname, owner, group, permissions, and time last modified information items are available

Syntax

DOPTNUM(directory-id)

Required Argument

directory-id
is a numeric variable that specifies the identifier that was assigned when the directory was opened by the DOPEN function.

Details

The information items that are available for a directory include directory pathname (the pathname of the directory-id), owner, group, permissions, and the time last modified. Therefore, this function returns a value of 5.
Examples:

Example 1: Retrieving the Number of Information Items

This example retrieves the number of system-dependent directory information items that are available for the directory MYDIR and closes the directory:

```bash
%let filrf=mydir;
%let rc=%sysfunc(filename(filrf, physical-name));
%let did=%sysfunc(dopen(&filrf));
%let infocnt=%sysfunc(doptnum(&did));
%let rc=%sysfunc(dclose(&did));
```

Example 2: Using DOPTNUM within a DATA Step

This example creates a data set that retrieves the number of system-dependent information items that are available for the MYDIR directory:

```bash
data _null_;  
  rc=filename("mydir", "physical-name");  
  did=dopen("mydir");  
  infocnt=doptnum(did);  
  rc=dclose(did);  
run;
```

FDELETE Function: UNIX

Deletes an external file or an empty directory.

Category: External Files

Restriction: This function is not supported on the CAS server.

See: FILENAME Function: UNIX

Syntax

FDELETE(<"">fileref<"">)

Required Argument

fileref

specifies the fileref that is assigned to the external file or directory. The fileref cannot be associated with a list of concatenated filenames or directories. If the fileref is associated with a directory, the directory must be empty. You must have permission to delete the file. See the UNIX manual page for chmod for more information about permissions.

In the DATA step, fileref must be enclosed in double quotation marks. In macro code, fileref must not be enclosed in quotation marks.

You can assign filerefs using the FILENAME statement or the FILENAME function. Under UNIX, fileref can also be an environment variable.
Details
FDELETE returns 0 if the operation was successful, or a nonzero number if it was not successful.

FEXIST Function: UNIX
Verifies the existence of an external file that is associated with a fileref.
Category: External Files
Restriction: This function is not supported on the CAS server.
See: “FEXIST Function” in SAS Functions and CALL Routines: Reference, FILENAME Function: UNIX

Syntax
FEXIST(<"fileref">)

Required Argument
fileref
specifies the fileref assigned to the external file or directory. In a DATA step, fileref can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the fileref. In macro code, fileref can be any expression.

You can assign filerefs using the FILENAME statement or the FILENAME external file access function. Under UNIX, fileref can also be an environment variable.

In a DATA step, fileref must be enclosed in double quotation marks. In macro code, fileref must not be enclosed in double quotation marks.

Details
The FEXIST function returns a value of 1 if the external file that is associated with fileref exists, and a value of 0 if the file does not exist.

FILEEXIST Function: UNIX
Verifies the existence of an external file by its physical filename.
Category: External Files
Restrictions: If you call the FILEEXIST function in a SAS session that is in a locked-down state, and the specified filename in the function has not been added to the lockdown path list, then the function fails. A file access error related to the locked-down data is not generated in the SAS log unless you specify the SYSMSG function. This function is not supported on the CAS server.
See: “FILEEXIST Function” in SAS Functions and CALL Routines: Reference
Syntax

FILEEXIST("filename")

Required Argument

filename

specifies a fully qualified physical filename of the external file. In a DATA step, filename can be a character expression, a string enclosed in quotation marks, or a DATA step variable. In macro code, filename can be any expression.

Under UNIX, filename can also be an environment variable.

Details

FILEEXIST returns 1 if the external file exists, and 0 if the external file does not exist.

You can check for the existence of a directory by using FILEEXIST.

FILENAME Function: UNIX

Assigns or deassigns a fileref for an external file, directory, or output device.

Category: External Files

Restrictions:

If the SAS session in which you are specifying the FILENAME function is in a locked-down state and the filename specified in the function has not been added to the lockdown path list, then the function fails. A file access error related to the locked-down data is not generated in the SAS log unless you specify the SYSMSG function.

This function is not supported on the CAS server.

UNIX specifics:

fileref can be assigned with an environment variable; valid values of device-type and host-options

See:

“FILENAME Function” in SAS Functions and CALL Routines: Reference

Syntax

FILENAME("fileref", "filename", "device-type", "host-options", directory-reference)

Required Arguments

fileref

specifies the fileref to assign to an external file. In a DATA step, fileref can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the fileref. In macro code, fileref is the name of a macro variable (without an ampersand) whose value contains the fileref to assign to the external file. For more information, see “FILENAME Function” in SAS Functions and CALL Routines: Reference.
Under UNIX, the `fileref` can be a UNIX environment variable. The `fileref` or environment variable that you specify must be enclosed in double quotation marks.

**filename** specifies the external file. Specifying a blank filename (" ") deassigns a `fileref` that was previously assigned.

Under UNIX, the filename differs according to the device type. For more information that is appropriate for each device, see “Device Information in the FILENAME Statement” on page 351. Remember that UNIX filenames are case sensitive.

In a DATA step, `filename` can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the filename. In macro code, `filename` can be any expression.

Optional Arguments

**device-type** specifies the type of device or the access method that is used if the fileref points to an input or output device or location that is not a physical file. It can be any one of the devices listed in “Device Information in the FILENAME Statement” on page 351. DISK is the default device type.

**host-options** are options that are specific to UNIX. You can use any of the options that are available in the FILENAME statement. See “FILENAME Statement: UNIX” on page 346 for a description of the host options.

**directory-reference** specifies the fileref that is assigned to the directory in which the external file resides.

Details

FILENAME returns a 0 if the operation is successful, and a nonzero number if it was not successful.

If you use the FTP access method to communicate with a remote system, SAS might return the following error message:

```
ERROR: Physical file does not exist.
```

This error is likely to occur when the fully qualified data set name is specified within single quotation marks. For example:

```
FILENAME fileref FTP 'system.dataset.name' USER='username'
    PASS='password' HOST='ip_address';
```
By default, SAS appends the profile prefix to the beginning of the data set name. To prevent the profile prefix from being appended, enclose the data set name with both double and single quotation marks:

```sql
FILENAME fileref FTP "'external_file'" USER='username'
    PASS='password' HOST='ip_address';
```

**FILENAME Function: UNIX**

Verifies whether a fileref has been assigned for the current SAS session.

**Category:** External Files  
**Restriction:** This function is not supported on the CAS server.

**See:**  
“FILENAME Function” in *SAS Functions and CALL Routines: Reference*

**Syntax**

```sql
FILEREF(<">fileref<">)
```

**Required Argument**

`fileref`  
specifies the fileref to be validated. In a DATA step, `fileref` can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the fileref. In macro code, `fileref` can be any expression.

In the DATA step, `fileref` must be enclosed in double quotation marks. In macro code, `fileref` must not be enclosed in quotation marks.

You can assign filerefs using the FILENAME statement or the FILENAME function. Under UNIX, `fileref` can also be an environment variable.

**Details**

A negative return code indicates that the fileref exists, but the physical file associated with the fileref does not exist. A positive value indicates that the fileref is not assigned. A value of zero indicates that the fileref and external file both exist.

**FINFO Function: UNIX**

Returns the value of a file information item for an external file.

**Category:** External Files  
**Restriction:** This function is not supported on the CAS server.

**UNIX specifics:** `information-item` is available

**See:**  
“FINFO Function” in *SAS Functions and CALL Routines: Reference*, “FOPEN Function” in *SAS Functions and CALL Routines: Reference*
Syntax

\textbf{FINFO}(file-id, <"information-item">)

Required Arguments

\textbf{file-id}

specifies the identifier that was assigned when the file was opened, generally by the FOPEN function.

\textbf{information-item}

specifies the name of the file information item to be retrieved. This value is a character value. \textit{Information-item} is either a variable containing a valid value or the valid value in quotation marks.

Under UNIX, \textit{information-item} for files can have one of the following values:

- Filename
- Owner Name
- Group Name
- Access Permission
- File Size (bytes)

If you concatenate filenames, then an additional \textit{information-item}, File List, is available.

If you are using pipe files, then the only valid value for \textit{information-item} is the PIPE command.

Details

The FINFO function returns the value of a system-dependent information item for an external file that was previously opened and assigned a \textit{file-id} by the FOPEN function. FINFO returns a blank if the value given for \textit{information-item} is invalid.

For an example of how to use the FINFO function, see “Example: File Attributes When Using the Pipe Device Type” on page 318.

\textbf{FOPTNAME Function: UNIX}

Returns the name of an item of information about an external file.

\begin{itemize}
  \item Category: External Files
  \item Restriction: This function is not supported on the CAS server.
  \item UNIX specifics: Information items available
  \item See: “FOPTNAME Function” in \textit{SAS Functions and CALL Routines: Reference}
\end{itemize}

Syntax

\textbf{FOPTNAME}(file-id, nval)
Required Arguments

**file-id**

specifies the identifier that was assigned when the file was opened, generally by the FOPEN function.

**nval**

specifies the number of the file information item to be retrieved. The following table shows the values that `nval` can have in UNIX operating environments for single, pipe, and concatenated files:

**Table 16.1  Possible Values for nval for the FOPTNAME Function**

<table>
<thead>
<tr>
<th>nval</th>
<th>Single File</th>
<th>Pipe Files</th>
<th>Concatenated Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Filename</td>
<td>PIPE Command</td>
<td>Filename</td>
</tr>
<tr>
<td>2</td>
<td>Owner Name</td>
<td>File List</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Group Name</td>
<td>Owner Name</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Access Permission</td>
<td>Group Name</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>File Size (bytes)</td>
<td>Access Permission</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>File Size (bytes)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Details

FOPTNAME returns a missing or null value if an invalid argument to FOPTNAME is used.

Example: File Attributes When Using the Pipe Device Type

The following example creates a data set that contains the NAME and VALUE attributes returned by the FOPTNAME function when you are using pipes:

```sas
data fileatt;
  length name $ 20 value $ 40;
  drop fid j infonum;
  filename mypipe pipe 'UNIX-command';
  fid=fopen("mypipe", "s");
  infonum=foptnum(fid);
  do j=1 to infonum;
    name=foptname(fid, j);
    value=finfo(fid, name);
    put 'File attribute' name 'has a value of ' value;
    output;
  end;
run;
```

The following statement appears in the SAS log.
Unix-command is the UNIX command or program where you are piping your output or where you are reading your input. This command or program must be either fully qualified or defined in your PATH environment variable.

Functions:
- “FINFO Function: UNIX” on page 316
- “FOPEN Function” in SAS Functions and CALL Routines: Reference
- “FOPTNUM Function: UNIX” on page 319

FOPTNUM Function: UNIX

Returns the number of information items that are available for an external file.

Category: External Files

Restriction: This function is not supported on the CAS server.

UNIX specifics: Information items available

See: “FOPTNUM Function” in SAS Functions and CALL Routines: Reference

Syntax

FOPTNUM(file-id)

Required Argument

file-id specifies the identifier that was assigned when the file was opened, generally by the FOPEN function.

Details

Under UNIX, five information items are available for all types of files:

- Filename
- Owner Name
- Group Name
- Access Permission
- File Size (bytes)
If you concatenate filenames, then an additional information item, File List, is available. If you are using piped files, then the only information item that is available is the PIPE command.

The open-mode specified in the FOPEN function determines the value that FOPTNUM returns.

Table 16.2  Open Mode and FOPTNUM Values

<table>
<thead>
<tr>
<th>Open Mode</th>
<th>FOPTNUM Value</th>
<th>Information Items Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
<td>6 for concatenated files</td>
<td>All information items available.</td>
</tr>
<tr>
<td>Input</td>
<td>5 for single files</td>
<td></td>
</tr>
<tr>
<td>Update</td>
<td>5 for concatenated files</td>
<td>All information items available.</td>
</tr>
<tr>
<td>Output</td>
<td>4 for single files</td>
<td>Because the file is open for output, the File Size information type is unavailable.</td>
</tr>
<tr>
<td>Sequential (using Pipe Device Type)</td>
<td>1</td>
<td>The only information item available is PIPE command.</td>
</tr>
</tbody>
</table>

For an example of how to use the FOPTNUM function, see “Example: File Attributes When Using the Pipe Device Type” on page 318.

Functions:
- “FINFO Function: UNIX” on page 316
- “FOPEN Function” in SAS Functions and CALL Routines: Reference
- “FOPTNAME Function: UNIX” on page 317

MODEEXIST Function: UNIX

Determines whether a product image exists in the release of SAS that you have installed.

Category: Numeric
Restriction: This function is not supported on the CAS server.
UNIX specifics: pathname is available
See: “MODEEXIST Function” in SAS Functions and CALL Routines: Reference

Syntax

`MODEEXIST('product-name' | 'pathname')`
Required Arguments

**product-name**
- specifies a character constant, variable, or expression that is the name of the product image that you are checking.

**pathname**
- specifies the pathname for the product image that you are checking.

Details
The MODEXIST function searches the directories that are listed in the **pathname** argument for an executable module. The name of the executable module is passed to MODEXIST. MODEXIST returns 1 if the module is found, and 0 if the module is not found.

---

**MOPEN Function: UNIX**

Opens a file by directory ID and member name, and returns either the file identifier or a 0.

**Category:** External Files

**Restriction:** This function is not supported on the CAS server.

**UNIX specifics:** OPEN modes

**See:** "MOPEN Function" in SAS Functions and CALL Routines: Reference

**Syntax**

`MOPEN(directory-id, member-name <, open-mode <, record-length <, record-format>>>)`

**Required Argument**

**open-mode**
- specifies the type of access to the file:
  
  - **A**: APPEND mode allows writing new records after the current end of the file.
  - **I**: INPUT mode allows reading only (default).
  - **O**: OUTPUT mode defaults to the OPEN mode specified in the host option in the FILENAME statement or function. If no host option is specified, it allows writing new records at the beginning of the file.
  - **S**: Sequential input mode is used for pipes and other sequential devices such as hardware ports.
  - **U**: UPDATE mode allows both reading and writing.
  - **W**: Sequential Update mode is used for pipes and other sequential devices such as ports.
Details

Note: This version is a simplified version of the MOPEN function syntax. For the complete syntax and its explanation, see “MOPEN Function” in SAS Functions and CALL Routines: Reference.

MOPEN returns the identifier for the file, or 0 if the file could not be opened.

PATHNAME Function: UNIX

Returns the physical name of a SAS library or an external file, or returns a blank.

Category: SAS File I/O
Restriction: This function is not supported on the CAS server.
See: “PATHNAME Function” in SAS Functions and CALL Routines: Reference

Syntax

PATHNAME((fileref | libref) <, search-reference>)

Required Arguments

fileref
specifies the fileref that is assigned to the external file. In a DATA step, fileref can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the fileref. In macro code, fileref can be any expression.

The value of fileref can be a UNIX environment variable.

libref
specifies the libref that is assigned to a SAS library. In a DATA step, libref can be a character expression, a string enclosed in quotation marks, or a DATA step variable whose value contains the libref. In macro code, libref can be any expression.

The value of libref can be a UNIX environment variable.

Optional Argument

search-reference
specifies whether to search for a fileref or a libref.

F specifies a search for a fileref.

L specifies a search for a libref.

Details

PATHNAME returns the physical name of an external file or SAS library.
PATHNAME returns a blank if fileref or libref is invalid.
For more information about using a UNIX environment variable for `fileref` or `libref`, see “FILENAME Function: UNIX” on page 314.

---

**PEEKLONG Function: UNIX**

Stores the contents of a memory address in a numeric variable on 32-bit and 64-bit platforms.

**Category:** Special

**Restriction:** This function is not supported on the CAS server.

**Interaction:** When a SAS server is in a locked-down state, the PEEKLONG function does not execute. For more information, see “SAS Processing Restrictions for Servers in a Locked-Down State” in *SAS Language Reference: Concepts*.

**UNIX specifics:** All

**See:** “PEEKLONG Function” in *SAS Functions and CALL Routines: Reference*

**Syntax**

```plaintext
PEEKCLONG(address, length)

PEEKLONG(address, length)
```

**Required Arguments**

- `address` specifies the character string that is the memory address.
- `length` specifies the data length.

**Details**

**CAUTION**

Use the PEEKLONG functions only to access information returned by one of the MODULE functions.

The PEEKLONG function returns a value of `length` that contains the data that starts at the memory `address`.

Here are the variations of the PEEKLONG functions:

- `PEEKCLONG` accesses character strings.
- `PEEKLONG` accesses numeric values.

Usually, when you need to use one of the PEEKLONG functions, you use `PEEKCLONG` to access a character string. The PEEKLONG function is mentioned for completeness.
RANK Function: UNIX

Returns the position of a character in the ASCII collating sequence.

Categories: Character, CAS

UNIX specifics: Uses ASCII collating sequence

See: “RANK Function” in SAS Functions and CALL Routines: Reference

Syntax

\[
\text{RANK}(x)
\]

Required Argument

\(x\)

specifies a character constant, variable, or expression that contains a character in the ASCII collating sequence. If the length of \(x\) is greater than 1, you receive the rank of the first character in the string.

Details

Because UNIX uses the ASCII character set, the RANK function returns an integer that represents the position of a character in the ASCII collating sequence.

SYSGET Function: UNIX

Returns the value of the specified operating environment variable.

Category: Special

Restriction: This function is not supported on the CAS server.

UNIX specifics: \(\text{environment-variable}\) is a UNIX environment variable

See: “SYSGET Function” in SAS Functions and CALL Routines: Reference

Syntax

\[
\text{SYSGET('environment-variable')}
\]

Required Argument

\(\text{environment-variable}\)

is the name of a UNIX environment variable.
Details

The SYSGET function returns the value of an environment variable as a character string. For example, this statement returns the value of the HOME environment variable:

```
here=sysget('HOME');
```

The environment variable name is case-specific on UNIX. Specify the name of the environment variable as it is stored in your UNIX environment.

**TRANSLATE Function: UNIX**

Replaces specific characters in a character expression.

**Categories:**
- Character
- CAS

**UNIX specifics:**
- to and from arguments are required

**See:**
- “TRANSLATE Function” in SAS Functions and CALL Routines: Reference
- “TRANWRD Function” in SAS Functions and CALL Routines: Reference

**Syntax**

```
TRANSLATE(source, to-1, from-1 <, ...to-n, from-n>)
```

**Required Arguments**

- **source** specifies a constant, variable, or expression that contains the original character value.

- **to** specifies the characters that you want TRANSLATE to use as substitutes. Enclose character values in quotation marks.

- **from** specifies the characters that you want TRANSLATE to change. Enclose character values in quotation marks.

**Details**

Under UNIX, you must specify pairs of to and from arguments or you can use a comma as a placeholder. Values of to and from correspond on a character-by-character basis. TRANSLATE changes the first character of from to the first character of to, and so on. If to has fewer characters than from, TRANSLATE changes the extra characters to blanks. If to has more characters than from, TRANSLATE ignores the extra characters. There is no functional difference between using several pairs of short arguments or fewer pairs of longer arguments.

In a DATA step, if the TRANSLATE function returns a value to a variable that has not been assigned a length, then that variable is assigned the length of the first argument.
Comparisons

The TRANWRD function differs from TRANSLATE in that it scans for words (or patterns of characters) and replaces a word with a second word (or pattern of characters). For more information about the TRANWRD function, see *SAS Functions and CALL Routines: Reference.*
Informats under UNIX

SAS Informats under UNIX

Dictionary

HEX Informat: UNIX

Converts hexadecimal positive binary values to either fixed-point or floating-point binary values.

Categories: Numeric

CAS

UNIX specifics: Floating-point representation

See: "HEXw. Informat" in SAS Formats and Informats: Reference
Syntax

$HEX_w.$

Syntax Description

$w$

specifies the field width of the input value and also specifies whether the final value is fixed-point or floating-point.

If $w<16$, $HEX_w.$ converts the input value to positive integer binary values, treating all input values as positive (unsigned). If $w$ is 16, $HEX_w.$ converts the input value to real binary (floating-point) values, including negative values.

Default: 8

Range: 1–16

Details

The $HEX_w.$ informat converts the hexadecimal representation of positive binary numbers to real floating-point binary values. The width value of the $HEX_w.$ informat determines whether the input represents an integer (fixed-point) or real (floating-point) binary number. When you specify a width of 1 through 15, the informat interprets the input hexadecimal as an integer binary number. When you specify 16 for the width value, the informat interprets the input hexadecimal as a floating-point value.

For more information, see "Reading and Writing Binary Data in UNIX Environments" on page 244.

$HEX$ Informat: UNIX

Converts hexadecimal data to character data.

Categories: Character

CAS

UNIX specifics: Values are interpreted as ASCII values

See: "$HEX_w.$ Informat" in SAS Formats and Informats: Reference

Syntax

$HEX_w.$

Syntax Description

$w$

specifies the number of digits of hexadecimal data.

If $w=1$, $HEX_w.$ pads a trailing hexadecimal 0. If $w$ is an odd number greater than 1, then $HEX_w.$ reads $w-1$ hexadecimal characters.
Details
The $HEXw.$ informat converts every two digits of hexadecimal data into one byte of character data. Use the $HEXw.$ informat to encode hexadecimal values into a character variable when your input data is limited to printable characters. SAS under UNIX interprets values that are read with this informat as ASCII values.

IB Informat: UNIX
Reads integer binary (fixed-point) values.

Categories:
- Numeric
- CAS

UNIX specifics:
- Byte values

See:
“IBw.d Informat” in SAS Formats and Informats: Reference

Syntax
IB\w.d

Syntax Description
\w
specifies the width of the input field.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>1–8</td>
</tr>
</tbody>
</table>

\d
specifies the power of 10 by which to divide the value. This argument is optional.

Range 0–10

Details
The IBw.d informat reads fixed-point binary values. For integer binary data, the high-order bit is the value's sign: 0 for positive values, 1 for negative. Negative values are represented in two's-complement notation. If the informat includes a \d value, the data value is divided by 10^d.

For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.
**PD Informat: UNIX**

Reads data that is stored in packed decimal format.

Categories: Numeric, CAS

UNIX specifics: data representation

See: “PDw.d Informat” in *SAS Formats and Informats: Reference*

**Syntax**

`PDw.d`

**Syntax Description**

- **w**
  - Specifies the width of the input field.
  - Default: 1
  - Range: 1–16

- **d**
  - Specifies the power of 10 by which to divide the value. This argument is optional.
  - Range: 0–31

**Details**

The PDw.d informat reads packed decimal data. Although it is usually impossible to enter packed decimal data directly from a console, many programs write packed decimal data.

Each byte contains two digits in packed decimal data. The value’s sign is the first byte. Because the entire first byte is used for the sign, you should specify at least a width of 2.

The PDw.d format writes missing numerical data as –0. When the PDw.d informat reads a value of –0, the result is a value of 0.

For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.

---

**PIB Informat: UNIX**

Reads positive integer binary (fixed-point) values.

Categories: Numeric, CAS
UNIX specifics:

See: “PIBw.d Informat” in SAS Formats and Informats: Reference

Syntax

`PIBw.d`

Syntax Description

`w`

specifies the width of the input field.

Default 1

Range 1–8

`d`

specifies the power of 10 by which to divide the value. This argument is optional.

Range 0–10

Details

The PIBw.d informat reads integer binary (fixed-point) values. Positive integer binary values are the same as integer binary (see “IB Informat: UNIX” on page 329), except that all values are treated as positive. Thus, the high-order bit is part of the value rather than the value’s sign. If the informat includes a `d` value, the data value is divided by $10^d$.

For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.

RB Informat: UNIX

Reads numeric data that is stored in real binary (floating-point) notation.

Categories: Numeric

CAS

UNIX specifics: Floating-point representation; supports single-precision numbers only for those applications that truncate numeric data

See: “RBw.d Informat” in SAS Formats and Informats: Reference

Syntax

`RBw.d`

Syntax Description

`w`

specifies the width of the input field.
Default 4
Range 2–8

\( d \)
specifies the power of 10 by which to divide the value. This argument is optional.
Range 0–10

Details

The RB\(w.d\) informat reads numeric data that is stored in real binary (floating-point) notation. SAS stores all numeric values in floating-point. It is usually impossible to enter floating-point binary data directly from a console, but many programs write floating-point binary data. Use caution if you are using the RB\(w.d\) informat to read floating-point data created by programs other than SAS because the RB\(w.d\) informat is designed to read only double-precision data.

All UNIX systems that are currently supported by SAS use the IEEE standard for floating-point representation. This representation supports both single-precision and double-precision floating-point numbers. Double-precision representation has more bytes of precision, and the data within the representation is interpreted differently. For example, for single-precision, the value of 1 in hexadecimal representation is \texttt{3F800000}. For double-precision, the hexadecimal representation of 1 is \texttt{3FF0000000000000}.

The RB\(w.d\) informat is designed to read only double-precision data. It supports widths less than 8 only for applications that truncate numeric data for space-saving purposes. RB4. does not expect a single-precision floating-point number; it expects a double-precision number truncated to four bytes. Using the example of 1 above, RB4. expects \texttt{3FF00000} to be the hexadecimal representation of the four bytes of data to be interpreted as 1. If given \texttt{3F800000}, the single-precision value of 1, a different number results.

External programs such as those programs that are written in the C and Fortran languages can produce only single-precision or double-precision floating-point numbers. No length other than four or eight bytes is allowed. RB\(w.d\) allows a length of 3 through 8, depending on the storage that you need to save.

The FLOAT4. informat has been created to read a single-precision floating-point number. If you read \texttt{3F800000} with the FLOAT4. informat, the result is a value of 1.

To read data created by a C or Fortran program, you need to decide on the proper informat to use. If the floating-point numbers require an eight-byte width, you should use the RB8. informat. If the floating point numbers require a four-byte width, you should use FLOAT4.

Consider the following C example:

```c
#include <stdio.h>
main() {
    FILE *fp;
    float x[3];
    fp = fopen("test.dat","wb");
    x[0] = 1; x[1] = 2; x[2] = 3;
    fwrite((char *)x,sizeof(float),3,fp);
    fclose(fp);
}
```
The file `test.dat` contains `3f8000004000000040400000` in hexadecimal representation.

The following statements read `test.dat` correctly:

```plaintext
data _null_;  
  infile 'test.dat';  
  input {x y z} (float4.);  
run;
```

Also available is the IEEEw.d informat, which reads IEEE floating-point data. On UNIX systems, IEEE8. is equivalent to RB8., and IEEE4. is equivalent to FLOAT4. IEEEw.d can be used on any platform, as long as the original IEEE binary data originated on a platform that uses the IEEE representation.

For more information, see “Reading and Writing Binary Data in UNIX Environments” on page 244.

---

**ZD Informat: UNIX**

Reads zoned decimal data.

**Categories:**
- Numeric
- CAS

**UNIX specifics:**
- Last byte includes the sign; data representation

**See:**
- “ZDw.d Informat” in *SAS Formats and Informats: Reference*

**Syntax**

**ZDw.d**

**Syntax Description**

- **w**
  - Specifies the width of the input field.
  - Default: 1
  - Range: 1–32

- **d**
  - Specifies the power of 10 by which to divide the value. This argument is optional.
  - Range: 0–31

**Details**

The ZDw.d informat reads zoned decimal data; it is also known as overprint trailing numeric format. Under UNIX, the last byte of the field includes the sign along with the last digit. The conversion table for the last byte is as follows:
### Table 17.1  Meaning of the Last Byte for the ZDw.d Informat

<table>
<thead>
<tr>
<th>Digit</th>

For more information, see “ZD Format: UNIX” on page 296 and “Reading and Writing Binary Data in UNIX Environments” on page 244.
Macro Facility under UNIX

About the Macro Facility under UNIX

Most features of the SAS macro facility are valid in all operating environments. This documentation discusses only those components of the macro facility that depend on the UNIX environment. For more information, see the following documentation:

- SAS Macro Language: Reference
- SAS Macro Facility Tips and Techniques
- the online Help for the macro facility

Automatic Macro Variables in UNIX Environments

The following automatic macro variables are valid in all operating environments, but their values are determined by the operating environment. All of the macro variables listed below apply to SAS 9.4 and to SAS Viya:
SYSCC
contains the current SAS condition code. Upon exit, SAS translates this condition code to a return code that has a meaningful value for the operating environment.

Note: The value of SYSCC might not match the return code returned by the operating system.

Note: When ERRORCHECK=NORMAL, the return code is 0, even if an error exists in a LIBNAME or FILENAME statement, or in a LOCK statement in SAS/SHARE software. Also, the SAS job or session does not end abnormally when the %INCLUDE statement fails due to a nonexistent file. For more information, see the “ERRORCHECK= System Option” in SAS System Options: Reference.

SYSDEVIC
contains the name of the current graphics device. The current graphics device is determined by the DEVICE system option. Contact your on-site SAS support personnel to determine which graphics devices are available at your site. For information, see “DEVICE System Option: UNIX” on page 392 and “DEVICE= System Option” in SAS/GRAPH: Reference.

SYSENV
reports whether SAS is running interactively. Values for SYSENV are FORE when the TERMINAL system option is in effect, and BACK when the NOTERMINAL system option is in effect.

SYSJOBID
lists the process identification number (PID) of the process that is executing SAS (for example, 00024).

SYSMAXLONG
returns the maximum long integer value allowed under UNIX, which is 9,007,199,254,740,992. On 32-bit systems, the maximum is 2,147,483,647.

SYSRC
holds the decimal value of the exit status code that is returned by the last UNIX command executed from your SAS session. The following output shows an interactive line mode SAS session that shows two sample SYSRC values:

Output 18.1 Sample SYSRC Values

1? x 'data';
/bin/ksh: data: not found
2? %put UNIX exit status code is &sysrc;
UNIX exit status code is 256
3? x 'date';
Tue Mar 15 09:41:27 CST 2011
4? %put UNIX exit status code is now &sysrc;
UNIX exit status code is now 0

SYSSCP
returns the abbreviation for your processor architecture, such as HP IPF, SUN 64, or AIX 64.
returns the name of the specific UNIX environment that you are using, such as HP-UX, SunOS, or AIX. This variable returns the same value that is returned by the UNIX command \texttt{uname}.

The arguments that can be entered with the following statements depend on the operating environment:

\%\texttt{SYSEXEC}

executes UNIX commands. It is similar to the X statement described in \textquote{Executing Operating System Commands from Your SAS Session} on page 17. The \%\texttt{SYSEXEC} statement enables you to execute operating environment commands immediately and, if necessary, determine whether they executed successfully by examining the value of the automatic macro variable \texttt{SYSRC}. You can use the \%\texttt{SYSEXEC} statement inside a macro or in open code. The form of the \%\texttt{SYSEXEC} statement is as follows, where \texttt{command} can be any UNIX command:

\%\texttt{SYSEXEC} \texttt{<command>};

For example, the following code writes the status of the default printer to your UNIX shell:

\$\texttt{sysexec lpstat};

Entering \%\texttt{SYSEXEC} without a UNIX command starts a new shell, except under the X interface to SAS. For more information, see \textquote{Executing Operating System Commands from Your SAS Session} on page 17.

The following functions have operating environment dependencies:

\%\texttt{SCAN}

searches for a word that is specified by its position in a string. Here is the form of the \%\texttt{SCAN} function:

\%\texttt{SCAN}\texttt{<argument,n,<delimiters>};

On ASCII systems, the default delimiters are the following:

\texttt{blank . < { + & ! $ * ) ; ^ - / , % |}

\%\texttt{SYSGET}

returns the character string that is the value of the environment variable passed as the argument. Both UNIX and SAS environment variables can be translated using the \%\texttt{SYSGET} function. A warning message is written if the global variable does not exist. Here is the form of the \%\texttt{SYSGET} function:

\%\texttt{SYSGET}\texttt{<environment-variable>}
For example, the following code writes the value of the HOME environment variable to the SAS log:

```sas
%let var1=%sysget(HOME); %put &var1;
```

---

**SAS System Options Used by the Macro Facility in UNIX Environments**

The following system options have operating environment dependencies:

**MSYMTABMAX**
specifies the maximum amount of memory available to all symbol tables (global and local, combined). Under UNIX, the default value for this option is 4M.

**MVARSIZE**
specifies the maximum number of bytes for any macro variable stored in memory. In SAS 9.4M3, the default value for this option became 65534.

**SASAUTOS**
specifies the AUTOCALL library. For more information, see “The SASAUTOS System Option” on page 339.

---

**Using Autocall Libraries in UNIX Environments**

**What Is an Autocall Library?**

An autocall library contains files that define SAS macros. The following sections discuss aspects of autocall libraries that are dependent on the operating environment. For more information, see SAS Macro Language: Reference.

**Available Autocall Macros**

There are two types of autocall macros, those macros that are provided by SAS, and those macros that you define yourself. To use the autocall facility, you must have the MAUTOSOURCE system option set.

When SAS is installed, the SASAUTOS system option is defined in the configuration file to refer to the location of the default macros supplied by SAS. The products licensed at your site determine the autocall macros that you have available. You can also define your own autocall macros and store them in one or more directories. SAS does not recognize autocall macros if their filenames are written in uppercase or in mixed case. Use only filenames that are lowercase.
Guidelines for Naming Macro Files

Macro names in SAS are case insensitive, but they all map to a lowercase filename. If you store autocall macros in a UNIX directory, the file extension must be `.sas`, and the filename must be entirely in lowercase. In the UNIX environment, each macro file in the directory must contain a macro definition with a macro name that matches the filename. For example, a file named `prtdata.sas` should define a macro named `prtdata`.

The SASAUTOS System Option

To use your own autocall macros in your SAS program, specify their directories with the SASAUTOS system option. For more information, see “SASAUTOS System Option: UNIX” on page 438.

Note: The SASAUTOS system option under UNIX does not recognize filenames that are in uppercase or mixed case.

You can set the SASAUTOS system option when you start SAS, or you can use it in an OPTIONS statement during your SAS session. However, autocall libraries specified with the OPTIONS statement override any previous specification.

If you use the CONFIG system option to specify a configuration file, add your autocall library to the library concatenation supplied by SAS. If you use the default configuration files (sasv9.cfg), specify your autocall library there.

Autocall libraries are searched in the order in which you specify them.

Example: Setting Up and Testing a Macro in an Autocall Library

This example shows how to set up and test a macro in an autocall library.

The following output shows the results of executing two UNIX (`cat`) commands to display the contents of two files, and a SAS command to run the autocall.sas program:
Output 18.2  AUTOCALL Library Example

$ cat maclib/testauto.sas
%macro testauto;
  x echo 'Autocall library is working.';
%mend testauto;
$ cat source/autocall.sas
filename sysautos ('!SASROOT/sasautos' '$HOME/test/sasautos');
options mautosource sasautos=(sysautos '$HOME/macros/maclib');
%testauto
%TestAuto
$ sas source/autocall.sas
Autocall library is working.
Autocall library is working.
Autocall library is working.
Statements under UNIX

This section describes SAS statements that exhibit behavior or syntax that is specific to UNIX environments. Each statement description includes a brief "UNIX specifics" section that explains which aspect of the statement is specific to UNIX. If the information under "UNIX specifics" says "all", then the statement is described only in this documentation. Otherwise, the statement is described in this documentation and in SAS DATA Step Statements: Reference.

Dictionary

ABORT Statement: UNIX

Stops executing the current DATA step, SAS job, or SAS session.

Valid in: DATA step

Category: Action
Restriction: This statement is not supported on the CAS server.
UNIX specifics: Values of n
See: “ABORT Statement” in SAS DATA Step Statements: Reference

Syntax

\[
\text{ABORT } \langle \text{ABEND | RETURN} \rangle \langle n \rangle;
\]

Details

The \( n \) option enables you to specify the value of the exit status code that SAS returns to the shell when it stops executing. The value of \( n \) can range from 0 to 255. Normally, a return code of 0 is used to indicate that the program ran with no errors. Return codes greater than 0 are used to indicate progressively more serious error conditions. Return codes of 0–6 and those codes that are greater than 977 are reserved for use by SAS.

For information about additional options, see “ABORT Statement” in SAS DATA Step Statements: Reference.

See Also

“Determining the Completion Status of a SAS Job in UNIX Environments” on page 29

ATTRIB Statement: UNIX

Associates a format, informat, label, or length with one or more variables.

Valid in: DATA step
Category: DATA step
Restriction: This statement is not supported on the CAS server.
UNIX specifics: Length specification
See: “ATTRIB Statement” in SAS DATA Step Statements: Reference

Syntax

\[
\text{ATTRIB variable-list-1 attribute-list-1 } \langle \ldots \text{variable-list-n attribute-list-n} \rangle;
\]

Required Argument

attribute-list

LENGTH=<$\.length$

specifies the length of the variables in variable-list. The minimum length that you can specify for a numeric variable depends on the floating-point format used by your system. Because most systems use the IEEE floating-point format, the minimum is 3 bytes.
FILE Statement: UNIX

Specifies the current output file for PUT statements.

Valid in: DATA step
Categories: File-Handling
CAS
Restrictions: The FILE statement cannot override or modify the device type that was set by a preceding FILENAME statement.
LOG is the only file-specification available on the CAS server.
The device-type argument is not available on the CAS server.
UNIX specifics: Valid values for file-specification, host-options, and encoding-value
See: “FILE Statement” in SAS DATA Step Statements: Reference

Syntax

FILE file-specification <device-type> <PERMISSION='permission-value'> <ENCODING='encoding-value'> <options> <host-options>;

Required Argument

file-specification can be any of the file specification forms that are discussed in “Accessing an External File or Device in UNIX Environments” on page 81.

Optional Arguments

device-type specifies the type of device or the access method that is used if the fileref points to an input device or output device or to a location that is not a physical file. For the complete list of device type values, see “FILE Statement” in SAS DATA Step Statements: Reference.

PERMISSION='permission-value' specifies permissions to set for the specified fileref. To specify more than one set of permission values, separate them with a comma within quotation marks.

Provide the permission-value in the following format:
A::<trustee_type>::<permissions>
The ‘A’ indicates that these are access permissions. No other values are currently supported.
The trustee_type can take the following values:

- u  user
- g  group (group owner of the file)
- o  other (all other users)

The permission value takes the letters r (Read), w (Write), and x (Execute), in that order. If you do not want to grant one of these permissions, enter a '-' in its place (for example, r-x or rw-).

Suppose that you want to have Read, Write, and Execute permission for a fileref. You also want to specify Read and Execute permission for the group owner of the file. Finally, you want to allow all other users to have only Read permission for the file. You can specify these options as follows:

```
permission='A::u::rwx,A::g::r-x,A::o::r--'
```

Supply a permission value for all three trustee types. Any trustee type that you omit from the list of permission values is denied all access to the specified fileref. For example, suppose you used the following permission values:

```
permission='A::u::rwx,A::g::r-x'
```

In this case, only the owner and the group owner would have access to the specified file. Any user other than the owner or group owner is denied all access to the file.

**ENCODING='encoding-value'**

specifies the encoding to use when writing to the output file. The value for ENCODING= indicates that the output file has a different encoding from the current session encoding.

When you write data to the output file, SAS transcodes the data from the session encoding to the specified encoding.

For valid encoding values, see “Overview to SAS Language Elements That Use Encoding Values” in SAS National Language Support (NLS): Reference Guide.

**options**

can be any of the options for the FILE statement that are valid in all operating environments. For a description of these options, see “FILE Statement” in SAS DATA Step Statements: Reference.

**host-options**

are specific to UNIX environments. These options can be any of the following:

**BLKSIZE=**

specifies the number of bytes that are physically written in one I/O operation. The default is 8K. The maximum is 1G–1.

**TERMSTR=**

controls the end-of-line delimiter in files that are formatted by UNIX. By default, either a line feed alone or a carriage return and a line feed indicate the end of a line. To explicitly define the end-of-line delimiter, specify one of the following values:

- CR  Carriage return.
- CRLF Carriage return line feed.
- LF  Line feed. This parameter is used to read files that are formatted by UNIX.
LRECL=
specifies the logical record length. Its value depends on the record format in effect (RECFM). In SAS 9.4, the default value for LRECL= is 32,767. If you are using fixed length records (RECFM=F), the default value for LRECL= is 256. The maximum record length is 1G.

- If RECFM=F, then the value for the LRECL= option determines the length of each output record. The output record is truncated or padded with blanks to fit the specified size.

  Note: When RECFM=F, LRECL= must be set to 256 when SAS 9.4 is communicating with a previous version of SAS.

- If RECFM=N, then the value for the LRECL= option must be at least 256.

- If RECFM=V, then the value for the LRECL= option determines the maximum record length. Records that are longer than the specified length are divided into multiple records.

MOD
indicates that data written to the file should be appended to the file.

NEW
OLD
specifies whether a new file or an existing file is used for output. If you specify NEW, a new file is to be opened for output. If the file already exists, it is deleted and re-created. If you specify OLD, the previous contents of the file are replaced. NEW is the default.

RECFM=
specifies the record format. Values for the RECFM= option are the following:

- D default format (same as variable).
- F fixed format. That is, each record has the same length. Do not use RECFM=F for external files that contain carriage-control characters.
- N binary format. The file consists of a stream of bytes with no record boundaries.
- P print format. SAS writes carriage-control characters.
- V variable format. Each record ends with a newline character.
- S370V variable S370 record format (V).
- S370VB variable block S370 record format (VB).
- S370VBS variable block with spanned records S370 record format (VBS).

UNBUF
tells SAS not to perform buffered Writes to the file on any subsequent FILE statement. This option applies especially when you are writing to a data collection device.

Details
The ENCODING= option is valid only when the FILE statement includes a file specification that is not a reserved fileref. If the FILE statement includes the ENCODING= argument and the reserved filerefs Log or Print as the file-
specification, then SAS issues an error message. The ENCODING= value in the FILE statement overrides the value of the ENCODING= system option.

You can set the permissions of the output file by issuing the umask command from within the SAS session. For more information, see “Executing Operating System Commands from Your SAS Session” on page 17.

See Also

Chapter 4, “Using External Files and Devices,” on page 79

FILENAME Statement: UNIX

 Associates a SAS fileref with an external file or output device; disassociates a fileref and external file; lists attributes of external files.

Valid in: Anywhere
Category: Data Access
Restrictions: When SAS is in a locked-down state, the following FILENAME statement access methods are not accessible (enabled) in UNIX: EMAIL, FTP, HADOOP, SOCKET, and URL. Your SAS server administrator can re-enable one or more of these access methods so that they are accessible when SAS is in the locked-down state. For more information, see “SAS Processing Restrictions for Servers in a Locked-Down State” in SAS Language Reference: Concepts.

This statement is not supported on the CAS server.

UNIX specifics: device-type, external-file, host-options, and encoding-value

See: “FILENAME Statement” in SAS Global Statements: Reference

Syntax

FILENAME fileref <device-type> 'external-file' <PERMISSION='permission-value'> <ENCODING='encoding-value'> <'host-options'> <LOCKINTERNAL= AUTO | SHARED>;
FILENAME fileref device-type '<external-file>' <ENCODING='encoding-value'> <'host-options'> <LOCKINTERNAL= AUTO | SHARED>;
FILENAME fileref ('pathname-1' … ‘pathname-n') <ENCODING='encoding-value'> <'host-options'> <LOCKINTERNAL= AUTO | SHARED>;
FILENAME fileref directory-name <ENCODING='encoding-value'> <LOCKINTERNAL= AUTO | SHARED>;
FILENAME fileref <access-method> 'external-file' access-information;
FILENAME fileref CLEAR | _ALL_ CLEAR;
FILENAME fileref LIST | _ALL_ LIST;

Required Arguments

fileref

is the name by which you reference the file. Under UNIX, the value of fileref can be an environment variable.
Note: You cannot clear a fileref that is defined by an environment variable. Filerefs that are defined by an environment variable are assigned for the entire SAS session.

For more information, see "Using Environment Variables to Assign Filerefs in UNIX Environments" on page 90.

'external-file'
differs according to device type. "Device Information in the FILENAME Statement" on page 351 shows the information appropriate to each device. Remember that UNIX filenames are case sensitive. For more information, see "Specifying Pathnames in UNIX Environments" on page 82.

Note: If a filename has leading blanks, then the blanks are trimmed.

Optional Arguments

**device-type**
specifies a device for the output, such as a disk, terminal, printer, pipe, and so on. The device-type keyword must follow *fileref* and precede *pathname*. "Device Information in the FILENAME Statement" on page 351 describes the valid device types. DISK is the default device type. If you are associating the fileref with a DISK file, then you do not need to specify the device type.

**PERMISSION='permission-value'**
specifies permissions to set for the specified fileref. To specify more than one set of permission values, separate them with a comma within quotation marks.

Provide the *permission-value* in the following format:

```
A::<trustee_type>::<permissions>
```

The 'A' indicates that these are access permissions. No other values are currently supported.

The trustee_type can take the following values:

- **u** user
- **g** group (group owner of the file)
- **o** other (all other users)

The permission value takes the letters *r* (Read), *w* (Write), and *x* (Execute), in that order. If you do not want to grant one of these permissions, enter a ' - ' in its place (for example, *r-x* or *rw-*)

Suppose that you want to have Read, Write, and Execute permission for a fileref. You also want to specify Read and Execute permission for the group owner of the file. Finally, you want to allow all other users to have only Read permission for the file. You can specify these options as follows:

```
permission='A::u::rwx,A::g::r-x,A::o::r--'
```

Supply a permission value for all three trustee types. Any trustee type that you omit from the list of permission values is denied all access to the specified fileref. For example, suppose you used the following permission values:

```
permission='A::u::rwx,A::g::r-x'
```
In this case, only the owner and the group owner would have access to the specified file. Any user other than the owner or group owner is denied all access to the file.

**ENCODING='encoding-value'**

specifies the encoding to use when reading from or writing to the external file. The value for ENCODING= indicates that the external file has a different encoding from the current session encoding.

When you read data from an external file, SAS transcodes the data from the specified encoding to the session encoding. When you write data to an external file, SAS transcodes the data from the session encoding to the specified encoding.

---

**Note:** The UPRINTER device type does not support the ENCODING option.

---

For valid encoding values, see “Overview to SAS Language Elements That Use Encoding Values” in SAS National Language Support (NLS): Reference Guide.

**'host-options'**

are specific to UNIX environments. These options can be any of the following:

**BLKSIZE=**

**BLK=**

specifies the number of bytes that are physically written or read in one I/O operation. The default is 64K. The maximum is 1G-1. If you specify RECFM=S370VBS, then you should specify BLKSIZE=32,760 to avoid errors with records longer than 255 characters.

**TERMSTR=**

controls the end-of-line delimiter in files that are formatted by UNIX. By default, either a line feed alone or a carriage return and a line feed indicate the end of a line. To explicitly define the end-of-line delimiter, specify one of the following values:

- **CR** Carriage return.
- **CRLF** Carriage return line feed. Use this value to read files that are formatted by a PC. CRLF is the default.
- **LF** Line feed.

If you are writing a file that is read on UNIX, specify TERMSTR=LF.

**LRECL=**

specifies the logical record length. Its value depends on the record format in effect (RECFM). In SAS 9.4, the default value for LRECL= is 32,767. If you are using fixed length records (RECFM=F), the default value for LRECL= is 256. The maximum length is 1G.

- If RECFM=F, then the value for the LRECL= option determines either the number of bytes to be read as one record or the length of each output record. The output record is truncated or padded with blanks to fit the specified size.

**Note:** When RECFM=F, LRECL= must be set to 256 when you are reading fixed length records that were created using the default value in a previous version of SAS.

- If RECFM=N, then the value for the LRECL= option must be at least 256.
If RECFM=V, then the value for the LRECL= option determines the maximum record length. Records that are longer than the specified length are divided into multiple records on output and truncated on input.

If RECFM=S370VBS, then you should specify LRECL=32,760 to avoid errors with records longer than 255 characters.

MOD
indicates that data written to the file should be appended to the file.

NEW
OLD
specifies whether a new or existing file is used for output. If you specify NEW, a new file is to be opened for output. If the file already exists, it is deleted and re-created. If you specify OLD, the previous contents of the file are replaced. NEW is the default.

RECFM=
specifies the record format. Values for the RECFM= option are the following:

D default format (same as variable).
F fixed format. That is, each record has the same length. Do not use RECFM=F for external files that contain carriage-control characters.
N binary format. The file consists of a stream of bytes with no record boundaries. N is not valid for the PIPE device type. If you do not specify the LRECL option, then by default SAS reads 256 bytes at a time from the file.
P print format. On output, SAS writes carriage-control characters.
V variable format. Each record ends with a newline character.
S370V variable S370 record format (V).
S370VB variable block S370 record format (VB).
S370VBS variable block with spanned records S370 record format (VBS). If you specify RECFM=S3270VBS, then you should specify BLKSIZE=32,760 and LRECL=32,760 to avoid errors with records longer than 255 characters.

The RECFM= option is used for both input and output.

LOCKINTERNAL=AUTO | SHARED
specifies the SAS system locking that is to be used for the files that are listed in a FILENAME statement. LOCKINTERNAL can have one of the following values:

AUTO
locks a file so that in a SAS session, if a user has Write access to a file, then no other users can have Read or Write access to the file. If a user has Read access to a file, no other user can have Write access to the file, but multiple users can have Read access.

SHARED
locks a file so that in a SAS session, two users do not have simultaneous Write access to the file. The file can be shared simultaneously by one user who has Write access and multiple users who have Read access.

Default AUTO
UNBUF tells SAS not to perform buffered Writes to the file on any subsequent FILE statement. This option applies especially when you are reading from or writing to a data collection device. As explained in SAS DATA Step Statements: Reference, it also prevents buffered Reads on INFILE statements.

pathname-1' ... 'pathname-n'
are pathnames for the files that you want to access with the same fileref. Use this form of the FILENAME statement when you want to concatenate filenames. Concatenation of filenames is available only for DISK files, so you do not have to specify the device-type. Separate the pathnames with either commas or blank spaces. Enclose each pathname in quotation marks. Table 3.3 on page 62 shows character substitutions that you can use when specifying a pathname. If the fileref that you are defining is to be used for input, then you can also use wildcards as described in “Using Wildcards in Pathnames (Input Only)” on page 84. Remember that UNIX filenames are case-sensitive.

directory-name
specifies the directory that contains the files that you want to access. For more information, see "Assigning a Fileref to a Directory (Using Aggregate Syntax)" on page 88.

access-method
specifies the access method or device type that is used if the fileref points to an input or output device or location that is not a physical file. “Device Information in the FILENAME Statement” on page 351 describes the information that is expected by the access method.

access-information
differs according to the access method. “Device Information in the FILENAME Statement” on page 351 shows the information appropriate to each access method.

CLEAR clears the specified fileref or, if you specify _ALL_, clears all filerefs that are currently defined.

Note: You cannot clear a fileref that is defined by an environment variable. Filerefs that are defined by environment variables are assigned for the entire SAS session.

_ALL_
refers to all filerefs currently defined. You can use this keyword when you are listing or clearing filerefs.

LIST writes to the SAS log the pathname of the specified fileref or, if you specify _ALL_, lists the definition for all filerefs that are currently defined. Filerefs defined as environment variables appear only if you have already used those filerefs in a SAS statement. If you are using the Bourne shell or the Korn shell, SAS cannot determine the name of a pre-opened file, so it displays the following string instead of a filename:

<File Descriptor number>

For more information, see “Using Environment Variables to Assign Filerefs in UNIX Environments” on page 90.
Details

File Locking

File locking of external files is controlled at the FILENAME statement level by the LOCKINTERNAL option. If you use the AUTO (default) value for LOCKINTERNAL, then SAS locks a file exclusively for one user who has Write access. SAS locks a file non-exclusively for multiple users who have Read access. For example, if a file is opened in UPDATE or OUTPUT mode, then all other access from internal processes are blocked. If a file is opened in INPUT mode, then multiple users can read the file, but UPDATE and OUTPUT functions are blocked.

If you use the SHARED value for LOCKINTERNAL, then SAS allows one user Write access to a file as well as allowing multiple users to read the file.

Device Information in the FILENAME Statement

The following table lists the relationship between device type or access method and the related external file.

Table 19.1  Device Information in the FILENAME Statement

<table>
<thead>
<tr>
<th>Device or Access Method</th>
<th>Function</th>
<th>External File</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTIVEMQ</td>
<td>enables SAS programs to send messages to and receive messages from an ActiveMQ message broker through the HTTP protocol.</td>
<td>is accessed through a URL using the ActiveMQ RESTful API. The ActiveMQ MessageServlet handles the integration between the HTTP requests and the ActiveMQ message dispatcher. For more information, see Application Messaging with SAS.</td>
</tr>
<tr>
<td>CATALOG</td>
<td>references a SAS catalog as an external file.</td>
<td>is a valid two-, three-, or four-part SAS catalog name followed by catalog options (if needed). See SAS Language Reference: Concepts for more information.</td>
</tr>
<tr>
<td>DATAURL</td>
<td>enables you to read data from user-specified text using the DATAURL access method.</td>
<td>is accessed directly from a data URL specification instead of a network location. For more information, see &quot;FILENAME Statement: DATAURL Access Method&quot; in SAS Global Statements: Reference.</td>
</tr>
<tr>
<td>DISK</td>
<td>associates the fileref with a DISK file.</td>
<td>is either the pathname for a single file or, if you are concatenating filenames, a list of pathnames separated by spaces or commas and enclosed in parentheses. The level of specification depends on your location in the file system. Table 3.3 on page 62 shows character substitutions that you can use when specifying a UNIX pathname.</td>
</tr>
<tr>
<td>Device or Access Method</td>
<td>Function</td>
<td>External File</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------</td>
<td>---------------</td>
</tr>
<tr>
<td>DUMMY</td>
<td>associates a fileref with a null device.</td>
<td>None. DUMMY enables you to debug your application without reading from or writing to a device. Output to this device is discarded.</td>
</tr>
<tr>
<td>EMAIL</td>
<td>sends electronic mail to an address.</td>
<td>is an address and email options. For more information, see “Sending Electronic Mail Using the FILENAME Statement (EMAIL)” on page 96.</td>
</tr>
<tr>
<td>FTP</td>
<td>reads from or writes to a file from any computer on a network that is running an FTP server.</td>
<td>is the pathname of the external file on the remote computer followed by FTP options. See SAS Language Reference: Concepts, and “Assigning Filerefs to Files on Other Systems (FTP, SFTP, and SOCKET Access Types)” on page 87 for more information. If you are transferring a file to UNIX from the z/OS operating environment and you want to use either the S370V or S370VB format to access that file, then the file must be of type RECFM=U and BLKSIZE=32,760 before you transfer it. If you FTP to a z/OS computer, only one member of a z/OS PDS can be written to at a time. If you need to write to multiple members at the same time, a z/OS PDSE or a UNIX System Services directory should be used.</td>
</tr>
<tr>
<td>Hadoop</td>
<td>enables you to access files on a Hadoop Distributed File System (HDFS) whose location is specified in a configuration file.</td>
<td>is the pathname of the external file in an HDFS followed by Hadoop options. For more information, see “FILENAME Statement: Hadoop Access Method” in SAS Global Statements: Reference.</td>
</tr>
<tr>
<td>JMS</td>
<td>enables SAS programs to send messages to and receive messages from any JMS API-compliant message service.</td>
<td>is accessed through the third-party Message-Oriented Middleware vendor’s JMS provider, which implements the JMS API specification. The specification must be found in the classpath. For more information, see Application Messaging with SAS.</td>
</tr>
<tr>
<td>PIPE</td>
<td>reads input from or writes output to a UNIX command.</td>
<td>is a UNIX command. For more information, see Chapter 5, “Printing and Routing Output,” on page 103.</td>
</tr>
<tr>
<td>Device or Access Method</td>
<td>Function</td>
<td>External File</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------</td>
<td>---------------</td>
</tr>
<tr>
<td>PLOTTER</td>
<td>sends output to a plotter.</td>
<td>is a device name and plotter options. For more information, see “Printing the Contents of a Window” on page 112, and “Using the PRINTTO Procedure in UNIX Environments” on page 114.</td>
</tr>
<tr>
<td>PRINTER</td>
<td>sends output to a printer.</td>
<td>is a device name and printer option. For more information, see “Printing the Contents of a Window” on page 112, and “Using the PRINTTO Procedure in UNIX Environments” on page 114.</td>
</tr>
<tr>
<td>SFTP</td>
<td>reads from or writes to a file from any host computer that you can connect to on a network with an SSHD server running.</td>
<td>is the pathname of the external file on the remote computer, followed by SFTP options. For more information, see “FILENAME Statement: SFTP Access Method” in SAS Global Statements: Reference, and “Assigning Filerefs to Files on Other Systems (FTP, SFTP, and SOCKET Access Types)” on page 87.</td>
</tr>
<tr>
<td>SOCKET(^1)</td>
<td>reads and writes information over a TCP/IP socket.</td>
<td>depends on whether the SAS application is a server application or a client application. In a client application, external-file is the name or IP address of the host and the TCP/IP port number to connect to, followed by any TCP/IP options. In a server application, external-file is the port number to create for listening, followed by the SERVER keyword, and then any TCP/IP options. See SAS DATA Step Statements: Reference for more information.</td>
</tr>
<tr>
<td>TEMP</td>
<td>associates a fileref with an external file stored in the Work library.</td>
<td>None</td>
</tr>
<tr>
<td>TERMINAL</td>
<td>associates a fileref with a terminal.</td>
<td>is the pathname of a terminal.</td>
</tr>
<tr>
<td>UPRINTER</td>
<td>sends output to the default printer that was set up through the Printer Setup dialog box.</td>
<td>None</td>
</tr>
<tr>
<td>Device or Access Method</td>
<td>Function</td>
<td>External File</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------</td>
<td>--------------</td>
</tr>
<tr>
<td>URL¹</td>
<td>enables you to use the URL of a file to access it remotely.</td>
<td>is the name of the file that you want to read from or write to on a URL server. The URL must be in one of these forms:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="http://hostname/file">http://hostname/file</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="http://hostname:portno/file">http://hostname:portno/file</a></td>
</tr>
<tr>
<td>WebDAV</td>
<td>enables you to use WebDAV (Web Distributed Authoring and Versioning) to read from or write to a file from any host machine that you can connect to on a network with a WebDAV server running.</td>
<td>is the name of the file that you want to read from or write to a WebDAV server. The external file must be in one of these forms:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="http://hostname/path-to-the-file">http://hostname/path-to-the-file</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="https://hostname/path-to-the-file">https://hostname/path-to-the-file</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="http://hostname:port/path-to-the-file">http://hostname:port/path-to-the-file</a></td>
</tr>
<tr>
<td></td>
<td></td>
<td><a href="https://hostname:port/path-to-the-file">https://hostname:port/path-to-the-file</a></td>
</tr>
<tr>
<td>ZIP</td>
<td>enables you to access ZIP files.</td>
<td>is the pathname of the ZIP file that enables ZIP zlib services to read from or write to a UNIX machine that supports zlib. For more information, see &quot;FILENAME Statement: ZIP Access Method&quot; in SAS Global Statements: Reference.</td>
</tr>
</tbody>
</table>

¹ This access method is not accessible (enabled) when SAS is in a locked-down state unless your system administrator has re-enabled it. For more information, see "SAS Processing Restrictions for Servers in a Locked-Down State" in SAS Language Reference: Concepts.

- Chapter 4, “Using External Files and Devices,” on page 79

FOOTNOTE Statement: UNIX

Writes up to 10 lines of text at the bottom of the procedure or DATA step output.

Valid in: Anywhere

Category: Output Control

Restriction: This statement is not supported on the CAS server.

UNIX specifics: Maximum length of footnote

See: “FOOTNOTE Statement” in SAS Global Statements: Reference
Syntax

%INCLUDE <source-1 > <... source-n> </SOURCE2> <S2=length> <ENCODING='encoding-value'> <host-options>>;

Required Argument

source
describes the location that you want to access with the %INCLUDE statement. The three possible sources are a file specification, internal lines, or keyboard entry. The file specification can be any of the file specification forms that are discussed in “Accessing an External File or Device in UNIX Environments” on page 81.

Note When using aggregate syntax, if the member name contains a leading digit, enclose the member name in quotation marks. If the member name contains a macro variable reference, use double quotation marks.

Optional Arguments

ENCODING='encoding-value'
specifies the encoding to use when reading from the specified source. The value for ENCODING= indicates that the specified source has a different encoding from the current session encoding.
When you read data from the specified source, SAS transcodes the data from the specified encoding to the session encoding.

For valid encoding values, see “Overview to SAS Language Elements That Use Encoding Values” in SAS National Language Support (NLS): Reference Guide.

**host-options**

consists of statement options that are valid under UNIX. The following options are available:

**BLKSIZE=block-size**

specifies the number of bytes that are physically read or written in an I/O operation. The default is 8K. The maximum is 1M.

**LRECL=record-length**

specifies the logical record length (in bytes). In SAS 9.4, the default value for LRECL= is 32,767. If you are using fixed length records (RECFM=F), the default value for LRECL= is 256. The value of record-length can range from 1 to 1,048,576 (1 MB).

**RECFM=record-format**

specifies the record format. The following values are valid under UNIX:

D  default format (same as variable).

F  fixed format. That is, each record has the same length.

N  binary format. The file consists of a stream of bytes with no record boundaries.

P  print format.

V  variable format. Each record ends with a newline character.

S370V  variable S370 record format (V).

S370VB  variable block S370 record format (VB).

S370VBS  variable block with spanned records S370 record format (VBS).

The S370 values are valid with files laid out as z/OS files only. That is, files are binary, have variable-length records, and are in EBCDIC format. If you want to use a fixed-format z/OS file, first copy it to a variable-length, binary z/OS file.

**Details**

If you specify any options in the %INCLUDE statement, remember to precede the options list with a forward slash (/).

For information about additional options, see “%INCLUDE Statement” in SAS Global Statements: Reference.

**See Also**

“Introduction to External Files and Devices in UNIX Environments” on page 80
INFILE Statement: UNIX

Identifies an external file to read with an INPUT statement.

Valid in: DATA step
Category: File-Handling
Restrictions: This statement is not supported on the CAS server.

The INFILE statement cannot override or modify the device type that was set by a preceding FILENAME statement.

You cannot read binary files using the INPUT statement without arguments.

UNIX specifics: Valid values for encoding-value, file-specification, and host-options

See: “INFILE Statement” in SAS DATA Step Statements: Reference

Syntax

INFILE file-specification <ENCODING='encoding-value'> <options> <host-options>;

Required Argument

file-specification can be any of the file specification forms that are discussed in the "Accessing an External File or Device in UNIX Environments" on page 81.

Optional Arguments

ENCODING='encoding-value'
specifies the encoding to use when reading from the external file. The value for ENCODING= indicates that the external file has a different encoding from the current session encoding.

When you read data from an external file, SAS transcodes the data from the specified encoding to the session encoding.

For valid encoding values, see "Overview to SAS Language Elements That Use Encoding Values" in SAS National Language Support (NLS): Reference Guide.

host-options are specific to UNIX environments. These options can be any of the following:

BLKSIZE=
BLK=

specifies the number of bytes that are physically read in one I/O operation. The default is 8K. The maximum is 1G–1.

TERMSTR=
controls the end-of-line delimiter in files that are formatted by UNIX. By default, either a line feed alone or a carriage return and a line feed indicate the end of a line. To explicitly define the end-of-line delimiter, specify one of the following values:

CR Carriage return.
CRLF  Carriage return line feed.
LF   Line feed. This parameter is used to read files that are formatted by UNIX.

LRECL=  specifies the logical record length. Its value depends on the record format in effect (RECFM). In SAS 9.4, the default value for LRECL= is 32,767. If you are using fixed length records (RECFM=F), the default value for LRECL= is 256. The maximum length is 1G.
- If RECFM=F, then the value for the LRECL= option determines the number of bytes to be read as one record.

Note: When RECFM=F, LRECL= must be set to 256 when SAS 9.4 is communicating with a previous version of SAS.
- If RECFM=N, then the value for the LRECL= option must be at least 256.
- If RECFM=V, then the value for the LRECL= option determines the maximum record length. Records that are longer than the specified length are truncated.

RECFM=  specifies the record format. The following values are valid under UNIX:

D     default format (same as variable).
F     fixed format. That is, each record has the same length.
N     binary format. The file consists of a stream of bytes with no record boundaries. If you do not specify the LRECL option, then, by default, SAS reads 256 bytes at a time from the file.
P     print format.
V     variable format. Each record ends with a newline character.
S370V variable S370 record format (V).
S370VB variable block S370 record format (VB).
S370VBS variable block with spanned records S370 record format (VBS).

Details

The ENCODING= option is valid only when the INFILE statement includes a file specification that is not a reserved fileref. If the INFILE statement includes the ENCODING= argument and the reserved filerefs DATALINES or DATALINES4 as a file-specification, then SAS issues an error message. The ENCODING= value in the INFILE statement overrides the value of the ENCODING= system option.

For information about additional options, see “INFILE Statement” in SAS DATA Step Statements: Reference.

See Also

Chapter 4, "Using External Files and Devices," on page 79
LENGTH Statement: UNIX

Specifies the number of bytes for storing variables.

Valid in: DATA step
Categories: Information
CAS
Restriction: In CAS, numeric variables shorter than 8 bytes are treated as 8 bytes.
UNIX specifics: Valid numeric variable lengths
See: “LENGTH Statement” in SAS DATA Step Statements: Reference

Syntax

LENGTH <variable-1> <...variable-n>anness length <DEFAULT=n>;

Required Arguments

length
can range from 3 to 8 for numeric variables under UNIX. The minimum length that you can specify for a numeric variable depends on the floating-point format used by your system. Because most systems use the IEEE floating-point format, the minimum is 3 bytes.

Restriction In CAS, numeric variables shorter than 8 bytes are treated as 8 bytes.

DEFAULT=n changes the default number of bytes that are used for storing the values of newly created numeric variables from 8 to the value of n. Under UNIX, n can range from 3 to 8.

Details

For information about additional options, see “LENGTH Statement” in SAS DATA Step Statements: Reference.

See Also

Chapter 11, “Data Representation,” on page 243

LIBNAME Statement: UNIX

Associates or disassociates a SAS library with a libref (a shortcut name); clears one or all librefs; lists the characteristics of a SAS library; concatenates SAS libraries; implicitly concatenates SAS catalogs; turns off file locking.

Valid in: Anywhere
Syntax

LIBNAME libref <engine>'SAS-library' <options> <engine/host-options>;
LIBNAME libref <engine>('library-1' , ..., 'library-n') <options>;
LIBNAME libref ('library-1' | libref-1 , ..., 'library-n' | libref-n);
LIBNAME libref CLEAR | _ALL _ CLEAR;
LIBNAME libref LIST | _ALL _ LIST;

Required Argument

libref
is any valid libref as documented in “LIBNAME Statement” in SAS Global Statements: Reference. SAS reserves some librefs for special system libraries. For more information about reserved librefs, see “Librefs Assigned by SAS in UNIX Environments” on page 65.

Optional Arguments

engine
is one of the library engines supported under UNIX. For a description of the engines, see “Details” on page 361. If no engine name is specified, SAS determines which engine to use as described in “Omitting Engine Names from the LIBNAME Statement” on page 363.

'SAS-library'
differs based on the engine that you specify and based on your current working directory. Table 19.36 on page 362 describes what each engine expects for this argument. Specify directory pathnames as described in “Specifying Pathnames in UNIX Environments” on page 61. You cannot create directories with the LIBNAME statement. The directory that you specify must already exist, and you must have permissions to it. Enclose the library name in quotation marks. Remember that UNIX pathnames are cases sensitive.

'library-n' | libref-n
are pathnames or librefs (that have been assigned) for the libraries that you want to access with one libref. Use these forms of the LIBNAME statement when you want to concatenate libraries. Separate the pathnames with either commas or blank spaces. Enclose library pathnames in quotation marks. Do not enclose librefs in quotation marks. For more information about concatenating libraries, see “Assigning a Libref to Several Directories (Concatenating Directories) in UNIX” on page 62.

options
are LIBNAME statement options that are available in all operating environments. For information about these options, see “LIBNAME Statement” in SAS Global Statements: Reference.
engine/host-options
  can be any of the options described in “Engine and Host Options” on page 364.

_ALL_
  refers to all librefs currently defined. You can use this keyword when you are
  listing or clearing librefs.

CLEAR
  clears the specified libref, or, if you specify _ALL_, clears all librefs that are
  currently defined. Sasuser, Sashelp, and Work remain assigned.

  Note: When you clear a libref defined by an environment variable, the variable
  remains defined, but it is no longer considered a libref. You can still reuse it,
  either as a libref or a fileref. For more information, see “Using Environment
  Variables as Librefs in UNIX Environments” on page 65.

  SAS automatically clears the association between librefs and their respective
  libraries at the end of your job or session. If you want to associate an existing
  libref with a different SAS library during the current session, you do not have to
  end the session or clear the libref. SAS automatically reassigns the libref when
  you issue a LIBNAME statement for the new SAS library.

LIST
  writes to the SAS log the engine, pathname, file format, access permissions, and
  so on, that are associated with the specified libref. If you specify _ALL_, LIST
  prints this information for all librefs that are currently defined. Librefs defined as
  environment variables appear only if you have already used those librefs in a
  SAS statement.

NOSETPERM
  specifies that permission settings are not inherited from one library member to
  another when the library members are opened with the same libref. If you have
  two assignments to a path, one with the NOSETPERM option and the other
  without, the two assignments are treated as if the paths do not match. The
  LIBNAME statement with the NOSETPERM option does not inherit permission
  settings.

  Once the NOSETPERM option is used to turn off permission settings for a libref,
  the option is in effect whenever you use the libref. There is no option that turns
  off the NOSETPERM option. To turn off the NOSETPERM option, submit the
  following statement:

  libname libref clear;

Details

Types of Engines

There are two main types of engines:

View engines
  enable SAS to read SAS views that are described by SAS/ACCESS software,
  the SQL procedure, and DATA step views. The use of SAS view engines is
  automatic because the name of the view engine is stored as part of the
  descriptor portion of the SAS data set.
Library engines
control access at the SAS library level. Every SAS library has an associated
library engine, and the files in that library can be accessed only through that
gine. There are two types of library engines:
native engines
access SAS files created and maintained by SAS. See the following table for a
description of these engines.
interface engines
treat other vendors' files as if they were SAS files. For more information, see the
following table and “Accessing BMDP, OSIRIS, or SPSS Files in UNIX
Environments” on page 73.

Table 19.2 Engine Names and Descriptions

<table>
<thead>
<tr>
<th>Engine Type</th>
<th>Name (Alias)</th>
<th>Description</th>
<th>SAS Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>V9 (BASE)</td>
<td>enables you to create new SAS</td>
<td>is the pathname of the directory containing the library.</td>
</tr>
<tr>
<td></td>
<td>V8</td>
<td>data sets and to access existing SAS data sets that were created with Version 8 or SAS 9. The V8 and V9 engines are identical. This engine enables Read access to data files that were created with some earlier releases of SAS, but this engine is the only one that supports SAS 9 catalogs. This engine allows for data set indexing and compression, and is also documented in SAS Language Reference: Concepts.</td>
<td></td>
</tr>
<tr>
<td>compatibility</td>
<td>V6</td>
<td>accesses any data file that was created by Releases 6.09 through 6.12. This engine is read-only.</td>
<td>is the pathname of the directory containing the library.</td>
</tr>
<tr>
<td>Engine Type</td>
<td>Name (Alias)</td>
<td>Description</td>
<td>SAS Library</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>servers</td>
<td>SPD Server</td>
<td>enables communication between a client session and a data server. You must have a license for the SAS Scalable Performance Data Server on your client computer to use this engine. See the SAS Scalable Performance Data Server: User's Guide for more information.</td>
<td>is the logical LIBNAME domain name for a SAS Scalable Performance Data Server (SPD Server) library on the server. The name server resolves the domain name into the physical path for the library.</td>
</tr>
<tr>
<td>MDDB</td>
<td></td>
<td>enables communication between a client session and an MDDB server. SAS/MDDB Server must be licensed on your client computer or on your server to use this engine.</td>
<td></td>
</tr>
<tr>
<td>transport</td>
<td>XPORT</td>
<td>accesses transport data sets. This engine creates computer-independent SAS transport files that can be used under all hosts running Release 6.06 or later of SAS. This engine is documented in Moving and Accessing SAS Files.</td>
<td>is the pathname of either a sequential device or a disk file.</td>
</tr>
<tr>
<td>XML</td>
<td>XML</td>
<td>generates (writes) and processes (reads) any XML document, which is an application- and computer-independent file.</td>
<td>is the pathname of the XML document.</td>
</tr>
<tr>
<td>interface</td>
<td>BMDP</td>
<td>provides Read-Only access to BMDP files. This engine is available only on AIX, HP-UX, and Solaris.</td>
<td>is the pathname of the data file.</td>
</tr>
<tr>
<td></td>
<td>OSIRIS</td>
<td>provides Read-Only access to OSIRIS files.</td>
<td>is the pathname of the data file.</td>
</tr>
<tr>
<td></td>
<td>SPSS</td>
<td>provides Read-Only access to SPSS files.</td>
<td>is the pathname of the data file.</td>
</tr>
</tbody>
</table>

Omitting Engine Names from the LIBNAME Statement

It is always more efficient to specify the engine name than have SAS determine the correct engine. However, if you omit an engine name in the LIBNAME statement or
if you define an environment variable to serve as a libref, SAS determines the appropriate engine.

If you have specified the ENGINE= system option, SAS uses the engine name that you specified. For a discussion of the ENGINE= system option, see "ENGINE= System Option: UNIX" on page 396.

**Note:** The ENGINE= system option specifies the default engine for libraries on disk only.

If you did not specify the ENGINE= system option, SAS looks at the extensions of the files in the given directory and uses these rules to determine an engine:

- If all the SAS data sets in the library were created by the same engine, the libref is assigned using that engine.

  **Note:** If the engine used to create the data sets is not the same as the default engine, then you are not able to create a view or stored program. For more information, see "Using Multiple Engines for a Library in UNIX Environments" on page 64.

- If there are no SAS data sets in the given directory, the libref is assigned using the default engine.

- If there are SAS data sets from more than one engine, the system issues a message about finding mixed engine types and assigns the libref using the default engine.

### Engine and Host Options

The LIBNAME statement accepts the following options:

**ENABLEDIRECTIO** specifies that direct I/O can be available for all files that are opened in the library that is identified in the LIBNAME statement.

**Note:** ENABLEDIRECTIO cannot be used with the $work directory.

A libref that is assigned to a directory with the ENABLEDIRECTIO option does not match another libref that is assigned to the same directory without the ENABLEDIRECTIO. The two librefs can point to the same directory, but the files that are opened using one libref are read from and written to using direct I/O. Files that are opened using the other libref are read from and written to using the regular disk I/O calls.

You must use the ENABLEDIRECTIO option with the USedefirectio= option to turn on direct I/O for the file or files whose libref is listed in the LIBNAME statement. The following example uses the ENABLEDIRECTIO and USedefirectio= LIBNAME options. In this case, all files that are referenced with libref test are opened for direct I/O:

LIBNAME test '.' ENABLEDIRECTIO USedefirectio=yes;

**TIP** The following example uses the ENABLEDIRECTIO LIBNAME option to enable files that are associated with the libref test to be opened for direct I/O. The USEDEFICTIO= data set option opens test.file1 for
direct I/O. test.file2 is not opened for direct I/O, although it is enabled for direct I/O.

LIBNAME test\'\.\'ENABLEDIRECTIO;
data test.file1(USEDIRECTIO=yes);
   ... more SAS statements ...
run;
data test.file2;
   ... more SAS statements ...
run;

FILELOCKS=NONE | FAIL | CONTINUE
specifies whether file locking is turned on or off for the files that are opened under the libref in the LIBNAME statement. The FILELOCKS statement option works like the FILELOCKS system option, except that it applies only to the files that are associated with the libref. The following values for the FILELOCKS statement option are available:

NONE
turns file locking off. NONE specifies that SAS attempts to open the file without checking for an existing lock on the file. NONE does not place an operating system lock on the file. These files are not protected from shared Update access.

FAIL
turns file locking on. FAIL specifies that SAS attempts to place an operating system lock on the file. Access to the file is denied if the file is already locked, or if it cannot be locked.

CONTINUE
turns file locking on. CONTINUE specifies that SAS attempts to place an operating system lock on the file. If the file is already locked by someone else, an attempt to open it fails. If the file cannot be locked for some other reason, the file is opened and a warning message is sent to the log. For example, you cannot lock a file if the file system does not support locking.

The FILELOCKS option in the LIBNAME statement applies to most of the SAS I/O files, such as data sets and catalogs, that are opened under the libref that is listed in the LIBNAME statement.

For the FILELOCKS statement option, RESET is not a valid value as it is when you use the FILELOCKS system option.

Use the FILELOCKS system option instead of the FILELOCKS statement option to set the locking behavior for your files. (The FILELOCKS statement option will be deprecated in a future release of SAS.) Note that the FILELOCK option in the LIBNAME statement overrides the LIBNAME system option. For more information, see the FILELOCKS system option in the UNIX operating environment. You can also specify any of the options supported by the Scalable Performance Data Server. See the Scalable Performance Data Server: User’s Guide at the SAS Technical Support site for a description of these options.

FILELOCKWAIT=n
specifies the number of seconds SAS waits for a locked file to become available to another process.

If the locked file is released before the number of seconds specified by n, then SAS locks the file for the current process and continues. If the file is still locked
when the number of seconds has been reached, then SAS writes a locked-file error to the log and the DATA step fails.

The valid values range from 0 to 600. The default value is 0.

Specifying the FILELOCKWAIT= option can have an adverse effect on one or more SAS/SHARE server and client sessions that are waiting for the release of a SAS file that is locked by another process. One or more wait conditions could lead to failed processes for a SAS/SHARE server and clients.

To prevent the possibility of a failed SAS/SHARE process, you can set FILELOCKWAIT=0, which cancels the amount of time that a SAS/SHARE server and clients would wait for the release of a locked file. Canceling the wait time would prevent a failed process. For more information, see the FILELOCKWAITMAX= system option. See also the FILELOCKWAITMAX= system option in the section about predefining a server library by using the LIBNAME statement in the SAS/SHARE User’s Guide.

TRANSFERSIZE=nK | nM
specifies the size of a large block of data that is read from a file that is opened.

n
specifies an integer value.

K
specifies the size of the block in kilobytes.

M
specifies the size of the block in megabytes.

To use the TRANSFERSIZE option, you must have files open for direct I/O. That is, both the ENABLEDIRECTIO and USEDIRECTIO= options must be in effect. If you use TRANSFERSIZE without the ENABLEDIRECTIO and USEDIRECTIO= options, the option is accepted, but it has no effect.

In the following example, 128k blocks of data are read from the test.file1 because this file is opened for direct I/O. test.file2 is not open for direct I/O, and the TRANSFERSIZE option has no effect on this file:

```
LIBNAME test'.'ENABLEDIRECTIO TRANSFERSIZE=128k;
data test.file1(USEDIRECTIO=yes);
  ... more SAS statements ...
run;
data test.file2;
  ... more SAS statements ...
run;
```

In the following example, all the files that are listed in the DATA statements read 128k blocks of data. This is because all the files are affected by the ENABLEDIRECTIO, USEDIRECTIO=, and TRANSFERSIZE options:

```
LIBNAME test'.'ENABLEDIRECTIO USEDIRECTIO=yes TRANSFERSIZE=128k;
data test.file1;
  ... more SAS statements ...
run;
data test.file2;
  ... more SAS statements ...
run;
data test.file3;
  ... more SAS statements ...
run;
```
USEDIRECTIO= YES | NO
if used with the ENABLEDIRECTIO statement option, turns on or turns off direct
file I/O for all the files associated with the libref listed in the LIBNAME statement.
You must use a permanent library, rather than a Work library, with
USEDIRECTIO.

Note: USEDIRECTIO cannot be used with the Work directory.

For more information, see “Engine and Host Options” on page 364.

Requirement
Use USEDIRECTIO= with the ENABLEDIRECTIO statement option to turn on
direct file I/O.

  page 43

SYSTASK Statement: UNIX

Executes asynchronous tasks.

Valid in: Anywhere
Category: Operating Environment
Restriction: This statement is not supported on the CAS server.
UNIX specifics: All

Syntax

SYSTASK COMMAND "operating-environment-command" <WAIT | NOWAIT>
<TASKNAME=taskname> <MNAME=name-variable> <STATUS=status-variable>
<SHCell="shell-command"> <CLEANUP>;

SYSTASK LIST <_ALL_ | taskname> <STATE> <STATVAR>;

SYSTASK KILL taskname <taskname...>;

Required Arguments

COMMAND
executes the operating–environment-command.
LIST
lists either a specific active task or all of the active tasks in the system. A task is active if it is running or if it has completed and has not been waited for using the WAITFOR statement.

KILL
forces the termination of the specified tasks.

operating-environment-command
specifies the name of a UNIX command (including any command-specific options) or the name of an X window system application. Enclose the command in either single or double quotation marks. If the command-specific options require quotation marks, repeat them for each option. For example:

SYSTASK COMMAND "xdialog -m "There was an error." -t "Error"" -o";

Note: If the command name is a shell alias, or if you use the shell special characters tilde (~) and asterisk (*) in a pathname within a command, you need to specify the SHELL option so that the shell processes the alias or special characters:

SYSTASK COMMAND "mv ~usr/file.txt /tmp/file.txt" shell;

In this example, by using the SHELL option, the ~usr path is expanded on execution and is not executed directly.

Note: The operating-environment-command that you specify cannot require input from the keyboard.

Optional Arguments

WAIT | NOWAIT
determines whether SYSTASK COMMAND suspends execution of the current SAS session until the task has completed. NOWAIT is the default. For tasks that start with the NOWAIT option, you can use the WAITFOR statement when necessary to suspend execution of the SAS session until the task has finished. For more information, see “WAITFOR Statement: UNIX” on page 371.

TASKNAME=taskname
specifies a name that identifies the task. Task names must be unique among all active tasks. A task is active if it is running or if it has completed and has not been waited for using the WAITFOR statement. Duplicate task names generate an error in the SAS log. If you do not specify a task name, SYSTASK automatically generates a name. If the task name contains a blank character, enclose it in quotation marks.

Task names cannot be reused, even if the task has completed, unless you either issue the WAITFOR statement for the task or you specify the CLEANUP option.
MNAME=name-variable

specifies a macro variable in which you want SYSTASK to store the task name that it automatically generated for the task. If you specify both the TASKNAME option and the MNAME option, SYSTASK copies the name that you specified with TASKNAME into the variable that you specified with MNAME.

STATUS=status-variable

specifies a macro variable in which you want SYSTASK to store the status of the task. Status variable names must be unique among all active tasks.

SHELL="shell-command"

specifies that the operating-environment-command should be executed with the operating system shell command. The shell expands shell special characters that are contained in the operating-environment-command. If you specify a shell-command, SYSTASK uses the shell command that you specify to invoke the shell. Otherwise, SYSTASK uses the default shell. Enclose the shell command in quotation marks.

Note: The SHELL option assumes that the SHELL command that you specify uses the -i option to pass statements. Usually, your shell command is sh, csh, ksh, or bash.

CLEANUP

specifies that the task should be removed from the LISTTASK output when the task completes. Once the task is removed, you can reuse the task name without issuing the WAITFOR statement.

If you have long-running jobs that use the SYSTASK command multiple times, use the WAITFOR statement or the CLEANUP option in the SYSTASK command to clear the memory. The WAITFOR statement releases memory by removing the information for all completed processes that were started by the SYSTASK command. The CLEANUP option clears memory when a specific job completes, and releases memory for further use. If you use the WAITFOR statement after a job has completed, the statement is ineffective because the job has already been cleaned up by the CLEANUP option.

_ALL_

refers to all librefs currently defined. With LIST, _ALL_ specifies to list this information for all librefs that are currently defined. Librefs defined as environment variables appear only if you have already used those librefs in a SAS statement.

Details

The SYSTASK statement enables you to execute host-specific commands from within your SAS session or application. Unlike the X statement, the SYSTASK statement runs these commands as asynchronous tasks, which means that these tasks execute independently of all other tasks that are currently running. Asynchronous tasks run in the background, so you can perform additional tasks while the asynchronous task is still running.

For example, to start a new shell and execute the UNIX cp command in that shell, you might use this statement:

```sas
systask command "cp /tmp/sas* ~/archive/" taskname="copyjob1"
status=copysts1 shell;
```

The return code from the cp command is saved in the macro variable COPYSTS1.
The output from the command is displayed in the SAS log.

Because the syntax between UNIX and a PC can be different, converting PC SAS jobs to run on UNIX might result in an error in the conversion process. For example, entering the following command results in an error:

```sql
systask command "md directory-name" taskname="mytask";
```

An error occurs because `md` is a “make directory” command on a PC, but has no meaning in UNIX. In the conversion process, `md` becomes `mkdir`. You must use the SHELL option in the SYSTASK statement because `mkdir` is built into the UNIX shell, and it is not a separate command as it is on a PC.

SAS writes the error message to the log.

**Note:** Program steps that follow the SYSTASK statements in SAS applications usually depend on the successful execution of the SYSTASK statements. Therefore, syntax errors in some SYSTASK statements can cause your SAS application to end abnormally.

There are two types of asynchronous processes that can be started from SAS:

**Task**

All tasks started with SYSTASK COMMAND are of type Task. For these tasks, if you do not specify STATVAR or STATE, then SYSTASK LIST displays the task name, type, and state, and the name of the status macro variable. You can use SYSTASK KILL to kill only tasks of type Task.

**SAS/CONNECT Process**

Tasks started from SAS/CONNECT with the SIGNON statement or command and RSBMIT statement are of type SAS/CONNECT Process. To display SAS/CONNECT processes, use the LISTTASK statement to displays the task name, type, and state. To terminate a SAS/CONNECT process, use the KILLTASK statement. For information about SAS/CONNECT processes, see the SAS/CONNECT User’s Guide.

**Note:** The preferred method for displaying any task (not just SAS/CONNECT processes) is to use the LISTTASK statement instead of SYSTASK LIST. The preferred method for ending a task is using the KILLTASK statement instead of SYSTASK KILL.

The SYSRC macro variable contains the return code for the SYSTASK statement. The status variable that you specify with the STATUS option contains the return code of the process started with SYSTASK COMMAND. To ensure that a task executes successfully, you should monitor both the status of the SYSTASK statement and the status of the process that is started by the SYSTASK statement.

If a SYSTASK statement cannot execute successfully, the SYSRC macro variable contains a nonzero value. For example, there might be insufficient resources to complete a task or the SYSTASK statement might contain syntax errors. With the SYSTASK KILL statement, if one or more of the processes cannot be killed, SYSRC is set to a nonzero value.

When a task is started, its status variable is set to NULL. You can use the status variables for each task to determine which tasks failed to complete. Any task whose status variable is NULL did not complete execution. If a task terminates abnormally, then its status variable is set to -1. For more information about the status variables, see “WAITFOR Statement: UNIX” on page 371.
Unlike the X statement, you cannot use the SYSTASK statement to start a new interactive session.

Statements:
- "WAITFOR Statement: UNIX" on page 371
- "X Statement: UNIX" on page 373

Other References:
- "Executing Operating System Commands from Your SAS Session" on page 17

**TITLE Statement: UNIX**

Specifies title lines for SAS output.

**Syntax**

```
TITLE <n> <'text' | "text">;
```

**Arguments**

- **n**
  - Specifies the relative line for the title.
- **text**
  - Specifies the title text.

**UNIX specifics:**
- Maximum length of title

In interactive modes, the maximum title length is 254 characters. Otherwise, the maximum length is 200 characters. If the length of the specified title is greater than the value of the LINESIZE option, the title is truncated to the line size.

**WAITFOR Statement: UNIX**

Suspends execution of the current SAS session until the specified tasks finish executing.

**Valid in:** Anywhere

**Category:** Operating Environment

**Restriction:** This statement is not supported on the CAS server.
UNIX specifics: All

Syntax

```sas
WAITFOR <_ANY_ | _ALL_> taskname <taskname...> <TIMEOUT=seconds>;
```

Required Argument

`taskname` specifies the name of the tasks that you want to wait for. For information about task names, see "SYSTASK Statement: UNIX" on page 367. The task names that you specify must match exactly the task names assigned through the SYSTASK COMMAND statement. You cannot use wildcards to specify task names.

Optional Arguments

`_ANY_ | _ALL_` suspends execution of the current SAS session until either one or all of the specified tasks finishes executing. The default setting is `_ANY_`, which means that as soon as one of the specified tasks completes executing, the WAITFOR statement then finishes executing.

`TIMEOUT=seconds` specifies the maximum number of seconds that WAITFOR should suspend the current SAS session. If you do not specify the TIMEOUT option, WAITFOR suspends execution of the SAS session indefinitely.

Details

The WAITFOR statement suspends execution of the current SAS session until the specified tasks finish executing or until the TIMEOUT= interval has elapsed. If the specified task was started with the WAIT option, then the WAITFOR statement ignores that task. For a description of the WAIT option, see "SYSTASK Statement: UNIX" on page 367.

For example, the following statements start three different X client programs and waits for them to complete:

```sas
systask command "xv" taskname=pgm1;
systask command "xterm" taskname=pgm2;
systask command "xcalc" taskname=pgm3;
waitfor _all_ pgm1 pgm2 pgm3;
```

The WAITFOR statement can be used to execute multiple concurrent SAS sessions. The following statements start three different SAS jobs and suspend the execution of the current SAS session until those three jobs have finished executing:

```sas
systask command "sas myprog1.sas" taskname=sas1;
systask command "sas myprog2.sas" taskname=sas2;
systask command "sas myprog3.sas" taskname=sas3;
waitfor _all_ sas1 sas2 sas3;
```

**Note:** In this method, SAS terminates after each command, which can result in reduced performance. SAS/CONNECT can also be used for executing parallel SAS sessions. See the SAS/CONNECT User's Guide for more information.
If you have long-running jobs that use the SYSTASK command multiple times, use the WAITFOR statement or the CLEANUP option in the SYSTASK command to clear the memory. The WAITFOR statement releases memory by removing the information for all completed processes that were started by the SYSTASK command. The CLEANUP option clears memory when a specific job completes, and releases memory for further use. If you use the WAITFOR statement after a job has completed, the statement is ineffective because the job has already been cleaned up by the CLEANUP option.

The SYSRC macro variable contains the return code for the WAITFOR statement. If a WAITFOR statement cannot execute successfully, the SYSRC macro variable contains a nonzero value. For example, the WAITFOR statement might contain syntax errors. If the number of seconds specified with the TIMEOUT option elapses, then the WAITFOR statement finishes executing, and SYSRC is set to a nonzero value if one of the following occurs:

- you specify a single task that does not finish executing
- you specify more than one task and the _ANY_ option (which is the default setting), but none of the tasks finishes executing
- you specify more than one task and the _ALL_ option, and any one of the tasks does not finish executing

Any task whose status variable is still NULL after the WAITFOR statement has executed did not complete execution. For a description of status variables for individual tasks, see “SYSTASK Statement: UNIX” on page 367.

---

**X Statement: UNIX**

Issues an operating environment command from within a SAS session.

Valid in: Anywhere
Category: Operating Environment
Restriction: This statement is not supported on the CAS server.
UNIX specifics: Valid operating system command
See: “X Statement” in SAS Global Statements: Reference
Syntax

\[ X \Leftarrow \text{operating-system-command}\; \]

Required Argument

*operating-system-command*

specifies the UNIX command. If you specify only one UNIX command, you do not need to enclose it in quotation marks. Also, if you are running SAS from the Korn shell, you cannot use aliases.

Details

The X statement issues a UNIX command from within a SAS session. SAS executes the X statement immediately.

Neither the X statement nor the %SYSEXEC macro program statement is intended for use during the execution of a DATA step. The CALL SYSTEM routine, however, can be executed within a DATA step. For an example, see “CALL SYSTEM Routine: UNIX” on page 304.

Note: The X statement is not supported without arguments under the X Window System.

SAS System Options under UNIX

Behavior or Syntax That Is Specific to UNIX Environments

This section describes SAS system options that have behavior or syntax that is specific to UNIX environments. Each system option description includes a brief "UNIX specifics" section that explains which aspect of the system option is specific
to UNIX. If the information under "UNIX specifics" is "all," then the system option is described only in this documentation.

Additional information about most system options is located in SAS System Options: Reference. However, some system options are specific to topics that are covered in other books. For example, system options that are related to security are documented in Encryption in SAS. For more information, see "SAS System Options Documented in Other SAS Publications" in SAS System Options: Reference.

---

When You Use Parentheses in a Command Line

On a command line, if arguments are enclosed in quotation marks, then you must use a backslash before the open parenthesis and close parenthesis. This enables UNIX to interpret the arguments correctly.

---

When the Value of a System Option Includes a Space

If the value of a system option includes a space, you must enclose the value in quotation marks on the command line or in a config file. The following examples show the correct syntax:

- `bufsize='3 k'
- `bottommargin='2 in'

If the value of a system option does not include a space, you do not need to enclose the value in quotation marks:

- `bufsize=3k
- `bottommargin=2in

---

Determining How a SAS System Option Was Set

Interactions between SAS options can lead to unintended consequences. For example, if you set both the FULLSTIMER system option and the NONOTES system option, the result is that no FULLSTIMER information is written to the SAS log. Because it is possible to set one option in a configuration file and the other option in an OPTIONS statement, the reason for such a problem might not be readily apparent.

When you issue a PROC OPTIONS statement with the VALUE option to query the value of an option, the value of the option appears in the SAS log. The method or location that was used to set that option also appears in the log. If the option was set in a configuration file, then the Config filename field lists the name of the file. For example, the following output is displayed in the SAS log when you query the value of the MEMSIZE system option:

```
proc options option=memsize value;
```
run;

Option Value Information for SAS Option MEMSIZE
Value: 100663296
Scope: SAS Session
How option value set: Config file
Config filename: /usr/local/SAS/SASFoundation/9.4/sasv9_local.cfg

You can issue a PROC OPTIONS statement to query the value of the WORK system option. The WORK value can be set from a server configuration file, an environment setting, or a command line setting. The WORK path is generated by combining the initial server-specified WORK path with a host-specific value and an executive suffix. The following example shows the information that is written to the SAS log:

    proc options option=WORK value;
    run;

Option Value Information for SAS Option WORK
Value: /sastemp/SAS_workA1234567_bcd89
Scope: SAS Session
How option value set: Config file
Config filename: /usr/local/SAS/SASFoundation/9.4/sasv9_local.cfg

Restricted System Options

Restricted options are system options whose values are determined by the site administrator. If they are restricted by your site administrator, then you cannot override them. The site administrator can create a restricted options table that specifies the option values that are restricted when SAS starts. Any attempt to modify a system option that is listed in the restricted options table results in a message to the SAS log. The message indicates that the system option has been restricted by the site administrator and cannot be updated.

The following system options can be restricted by a site administrator in a UNIX environment:

- AUTHPROVIDERDOMAIN
- AUTOSAVELOC
- BUFNO
- BUFSIZE
- CATCACHE
- CLEANUP
- DEVICE
- ECHO
- EDITCMD
- EMAILSYS
- FILELOCKS
- FILELOCKWAIT=
- FMTSEARCH
- OPLIST
- PATH
- PRIMARYPROVIDERDOMAIN=
- PRINTCMD
- REALMEMSIZE
- RSASUSER
- RTRACE
- RTRACELOC
- SASAUTOS
- SASHELP
- SASSCRIPT
- SET
- SORTANOM
For more information, see these resources:

- “Restricted Options” in SAS System Options: Reference

Dictionary

ALIGNSASIOFILES System Option: UNIX

Aligns the pages of data in a SAS data set.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: Input Control: Data Processing

PROC OPTIONS

GROUP= SASFILES

Default: ALIGNSASIOFILES

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-ALIGNSASIOFILES | -NOALIGNSASIOFILES
Without Arguments
There are no required arguments.

Details
A SAS data set consists of a header followed by one or more pages of data. Normally, the header size is 8K in the UNIX operating environment. ALIGNSASIOFILES forces the header to be the same size as the data page, enabling the pages to align to boundaries that allow for more efficient I/O.

ALTLOG System Option: UNIX

Specifies the destination for a copy of the SAS log when SAS is running in batch mode.

Valid in:
SAS 9.4: Configuration file, SAS invocation, SASV9_OPTIONS environment variable,
SAS Viya: Not included

Category:
Environment Control: Files

PROC OPTIONS GROUP= ENVFILES

Default:
NOALTLOG

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax
–ALTLOG file-specification | –NOALTLOG

Required Arguments

-ALTLOG file-specification
specifies the location where an alternate SAS log is to be written. The file-specification argument can be any valid UNIX path to a directory, a filename, or an environment variable that is associated with a path. If you specify only the path to a directory, the SAS log is placed in a file in the specified directory. The name of the file is filename.log, where filename is the name of your SAS job. If you are running SAS interactively and specify only the path to a directory, the log is written to a file named sas.log within that path.

-NOALTLOG
specifies that the SAS log is not copied.

Details
ALTLOG Basics
The ALTLOG system option specifies a destination to which a copy of the SAS log is written. All messages that are written to the SAS log are also written to the location...
specified in `file-specification`. You can use this option to capture log output for printing.

**Note:** You can use the `LOG` option in the `PRINTTO` procedure to redirect any portion of the log to an external file. The code for `PROC PRINTTO` does not appear in the SAS log for the current session, but it does appear in the SAS log that you created with the `ALTLOG` system option.

**Note:** When SAS is started with the `OBJECTSERVER` and `NOTERMINAL` system options and no log is specified, SAS discards all log and alternate log messages.

### Using Directives with ALTLOG

Using directives in the `ALTLOG` system option enables you to control when log copies are open and closed, and how they are named, based on real-time events such as time, month, and day of week. For a list of directives, see "`LOGPARM=` System Option" in SAS System Options: Reference.

### See Also

**Options:**
- "ALTPRINT System Option: UNIX" on page 381
- Chapter 30, "PRINTTO Procedure," on page 503

**Other References:**
- "The SAS Log" in SAS Language Reference: Concepts
- "Using SAS System Options to Route Output" on page 116

---

### ALTPRINT System Option: UNIX

Specifies the destination for the output files from SAS procedures when SAS is running in batch mode.

**Valid in:**
- SAS 9.4: Configuration file, SAS invocation, SASV9_OPTIONS environment variable
- SAS Viya: Not included

**Category:** Environment Control: Files

**PROC OPTIONS GROUP=**
- ENVFILES

**Default:**
- NOALTPRINT

**UNIX specifics:**
- all

**Note:** This option cannot be restricted by a site administrator. For more information, see "Restricted Options" in SAS System Options: Reference.
Syntax

-ALTPRINT file-specification | -NOALTPRINT

Required Arguments

-ALTPRINT file-specification
specifies the location for copies of procedure output to be written. The file-specification argument can be any valid UNIX path to a directory, a filename, or an environment variable that is associated with a path. If you specify only the path to a directory, the copy is placed in a file in the specified directory. The name of the file is filename.lst, where filename is the name of your SAS job. If you are running SAS interactively and specify only the path to a directory, the output is written to a file named sas.lst.

-NOALTPRINT
causes any previous ALTPRINT specifications to be ignored.

Details

The ALTPRINT system option specifies a destination to which copies of the SAS procedure output file are written. All messages that are written to the SAS procedure output file are also written to the location specified in file-specification. You can use this option to capture the procedure output for printing.

See Also

System Options:

- "ALTLOG System Option: UNIX" on page 380

Other References:

- "Using SAS System Options to Route Output" on page 116

APPEND System Option: UNIX

Used when SAS starts; appends the specified value to the existing value at the end of the specified system option.

Category: Environment Control: Files

PROC OPTIONS GROUP= ENVFILES

Default: None

UNIX specifics: Configuration file, SAS command syntax

Note: This option cannot be restricted by a site administrator. For more information, see "Restricted Options" in SAS System Options: Reference.
Syntax

**-APPEND**  *system-option new-option-value*

Required Arguments

- **system-option**
  - can be AUTOEXEC, CMPLIB, FMTSEARCH, HELPLOC, MAPS, MAPSGFK, MSG, SASAUTOS, SASHELP, SASSCRIPT, or SET.

- **new-option-value**
  - is the new value that you want to append to the current value of *system-option*. This value can be any value that you could specify for *system-option* if *system-option* is set using the OPTIONS statement.

Restriction

- The value for the FMTSEARCH system option applies only to format catalogs. It does not apply to CAS format libraries. For information about CAS format library search order, see “CAS Statement” in *SAS Cloud Analytic Services: User’s Guide*.

Details

By default, if you specify the AUTOEXEC, CMPLIB, FMTSEARCH, HELPLOC, MAPS, MSG, SASAUTOS, SASHELP, SASSCRIPT, or SET system option more than one time, the last value that is specified is the value that SAS uses. If you want to add additional pathnames to the pathnames already specified by one of these options, you must use the APPEND system option to add the additional pathnames. For example, if you enter the following SAS command, the only location in which SAS looks for help files is `/apps/help`. The output of PROC OPTIONS shows only `/apps/help`:

```
sas -helploc /sas/help -append helploc /apps/help
```

If you want SAS to look first in `/sas/help`, and then in `/apps/help`, use the APPEND option.

```
sas -helploc /sas/help -append helploc /apps/help
```

For the value of the HELPLOC option, PROC OPTIONS now shows the following:

```
(''/sas/help' '/apps/help')
```

See Also

**System Options**:  
- “**APPEND= System Option**” in *SAS System Options: Reference*
- “**INSERT System Option: UNIX**” on page 412
AUTOEXEC System Option: UNIX

Specifies the location of the SAS autoexec file.

Category: Environment Control: Files

PROC OPTIONS GROUP=

Default: autoexec.sas (see "Details" on page 384)

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-AUTOEXEC file-specification | -NOAUTOEXEC

-AUTOEXEC (file-specification-1 <...file-specification-n>)

Required Arguments

file-specification

specifies the SAS autoexec file to be used instead of the default autoexec.sas file. The file-specification argument can be a valid filename or an environment variable that is associated with a pathname. For more information, see “Customizing Your SAS Session By Using Configuration and Autoexec Files” on page 25.

-NOAUTOEXEC

specifies that SAS is not to process any autoexec files.

Details

The Autoexec File

The AUTOEXEC system option specifies the autoexec file. The autoexec file contains SAS statements that are executed automatically when you invoke SAS or when you start another SAS process. The autoexec file can contain any SAS statements. For example, your autoexec file can contain LIBNAME statements for SAS libraries that you access routinely in SAS sessions. You can override the default autoexec file using the AUTOEXEC system option.

SAS looks for the AUTOEXEC system option in the following order. It uses the first AUTOEXEC system option that it finds:

  1  in the command line
  2  in the SASV9_OPTIONS environment variable
  3  in the configuration file
SAS uses the first AUTOEXEC option that it encounters and ignores all others. If neither the AUTOEXEC nor NOAUTOEXEC system option is found, SAS looks for the autoexec file in three directories in the following order:

1. your current directory
2. your home directory
3. the `!SASROOT` directory (For more information, see Appendix 1, “The !SASROOT Directory,” on page 521.)

SAS uses the first autoexec file that it finds to initialize the SAS session.

If you want to see the contents of the autoexec file for your session, use the ECHOAUTO system option when you invoke SAS. If you want to identify the data sources that the autoexec file is using, use the PROC OPTIONS statement:

```sas
proc options option=autoexec value;
run;
```

Inserting and Appending Autoexec Files

INSERT adds files to be executed before the autoexec file, and APPEND adds files to be executed after the autoexec file. You can concatenate files in your autoexec file by using the following system options with the AUTOEXEC system option: INSERT on page 412 and APPEND on page 382. The autoexec file is always a UNIX file. If your filename contains embedded blanks or special characters, you must enclose the filename in quotation marks. Otherwise, quotation marks are optional when one or more filenames are specified.

You can use the following syntax to concatenate autoexec files:

```
-autoexec "(/path1/autoexec.sas /path2/autoexec.sas /path3/autoexec.sas)"
```

You can use the following syntax with the INSERT system option:

```
-insert autoexec "a.sas" -insert autoexec "b.sas"
```

You can use the following syntax with the APPEND system option:

```
-append autoexec "a.sas" -append autoexec "b.sas"
```

**System Options:**

- “APPEND System Option: UNIX” on page 382
- “INSERT System Option: UNIX” on page 412

**Other References:**

- “Customizing Your SAS Session By Using System Options” on page 21

AUTOSAVELOC System Option: UNIX

Specifies the location of the Program Editor autosave file.
Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Not included

Category: Environment Control: Display

PROC OPTIONS GROUP=ENVDISPLAY

Default: None

UNIX specifics: valid values of pathname

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “AUTOSAVELOC= System Option” in SAS System Options: Reference

Syntax

-AUTOSAVELOC fileref | pathname

AUTOSAVELOC fileref | pathname

Required Arguments

fileref
specifies a fileref to the location where the autosave file is saved.

pathname
specifies the pathname, including the filename, of the autosave file. The pathname must be a valid UNIX pathname.

Details

By default, SAS saves the Program Editor autosave file, pgm.asv, in the open folder. You can use the AUTOSAVELOC system option to specify a different location for the autosave file.

See Also

Commands:
- “SETAUTOSAVE Command: UNIX” on page 264

---

BUFNO System Option: UNIX

Specifies the number of buffers to be allocated for processing a SAS data set.

Category: Files: SAS Files
PROC OPTIONS GROUP=

Default: 1

UNIX specifics: default value

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “BUFNO= System Option” in SAS System Options: Reference

Syntax

- BUFNO n | nK | nM | nG | hexX | MIN | MAX

BUFNO=n | nK | nM | nG | hexX | MIN | MAX

Required Arguments

n | nK | nM | nG

specifies the number of buffers in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 buffers, a value of .782k specifies 801 buffers, and a value of 3m specifies 3,145,728 buffers.

Note: You can also specify the KB, MB, or GB syntax notations.

hexX

specifies the number of buffers as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx specifies 45 buffers.

MIN

sets the number of buffers to 0, and requires SAS to use the default value of 1.

MAX

sets the number of buffers to 2,147,483,647.

Details

The number of buffers is not a permanent attribute of the data set; it is valid only for the current SAS session or job.

BUFNO= applies to SAS data sets that are opened for input, output, or update.

Using BUFNO= can improve execution time by limiting the number of input/output operations that are required for a particular SAS data set. The improvement in execution time, however, comes at the expense of increased memory consumption.

Under UNIX, the maximum number of buffers that you can allocate is determined by the amount of memory available.
BUFSIZE System Option: UNIX

Specifies the size of a permanent buffer page for an output SAS data set.

Categories: Files: SAS Files
System Administration: Performance

PROC OPTIONS GROUP=

Default: 0

UNIX specifics: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “BUFSIZE= System Option” in SAS System Options: Reference

Syntax

-BUFSIZE n | nK | nM | nG | hexX | MAX
BUFSIZE=n | nK | nM | nG | hexX | MAX

Required Arguments

n | nK | nM | nG
specifies the buffer page size in multiples of 1 (bytes); 1,024 (kilobytes);
1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 bytes, a value of .782k specifies 801 bytes, and a value of 3m specifies 3,145,728 bytes.

Note: You can also specify the KB, MB, or GB syntax notations.

hexX
specifies the buffer page size as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx sets the buffer page size to 45 bytes.

MAX
sets the buffer page size to 2,147,483,647.

Details
The buffer page size can range from 1K to 2G–1.
If you specify a nonzero value when you create a SAS data set, the BASE engine uses that value. If that value cannot hold at least one observation or is not a multiple of 1K, the engine rounds the value up to a multiple of 1K.

CATCACHE System Option: UNIX

Specifies the number of SAS catalogs to keep open in cache memory.

Category: Files: SAS Files

PROC OPTIONS GROUP=SASFILES

Default: 0

UNIX specifics: Valid values for \( n \)

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “CATCACHE= System Option” in SAS System Options: Reference

Syntax

- CATCACHE \( n \mid nK \mid \text{MIN} \mid \text{MAX} \)

Required Arguments

\( n \mid nK \)

specifies the number of open-file descriptors to keep in cache memory in multiples of 1 (\( n \)) or 1,024 (\( nK \)). You can specify decimal values for the number of kilobytes. For example, a value of 8 specifies 8 open-file descriptors, a value of \( .782K \) specifies 801 open-file descriptors, and a value of \( 3K \) specifies 3,072 open-file descriptors.

If \( n > 0 \), SAS places up to that number of open-file descriptors in cache memory, instead of closing the catalogs.

Note: You can also specify the KB syntax notation.

\( \text{MIN} \)

sets the number of open-file descriptors that are kept in cache memory to 0.

\( \text{MAX} \)

sets the number of open-file descriptors that are kept in cache memory to 32,767.

Details

By using the CATCACHE system option to specify the number of SAS catalogs to keep open, you can avoid repeatedly opening and closing the same catalogs.
CLEANUP System Option: UNIX

Specifies how to handle out-of-resource conditions.

Category: Environment Control: Error Handling

PROC OPTIONS GROUP=ERRORHANDLING

Default: CLEANUP for interactive modes; NOCLEANUP otherwise

UNIX specifics: behavior when running in interactive line mode and batch mode

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “CLEANUP System Option” in SAS System Options: Reference

Syntax

-CLEANUP | -NOCLEANUP
CLEANUP | NOCLEANUP

Required Arguments

CLEANUP

specifies that during the entire session, SAS attempts to perform automatic, continuous cleanup of resources that are not essential for execution. Nonessential resources include those resources that are not visible to the user (for example, cache memory) and those resources that are visible to the user (for example, the Keys window).

CLEANUP does not prompt you before SAS attempts to clean up your disk. However, when an out-of-disk-space condition occurs and your display is attached to the process, you are prompted with a menu selection even if the CLEANUP option is on. If you do not want to be prompted for out-of-disk-space conditions, use the CLEANUP option with the NOTERMINAL option.

When the CLEANUP option is on, SAS performs automatic continuous cleanup. If not enough resources are recovered, the request for the resource fails, and an appropriate error message is written to the SAS log.

CLEANUP is the default in batch mode because there is no display attached to the process to accommodate prompting.
NOCLEANUP specifies that SAS allows the user to choose how to handle an out-of-resource condition. When NOCLEANUP is in effect and SAS cannot execute because of a lack of resources, SAS automatically attempts to clean up resources that are not visible to the user (for example, cache memory). However, resources that are visible to the user (for example, the Keys window) are not automatically cleaned up. Instead, SAS prompts you before attempting to clean up your disk.

Details

The CLEANUP system option indicates whether you should be prompted with a menu of items to be cleaned up when SAS encounters an out-of-resource condition. In batch mode, SAS ignores this option, and if an out-of-resource condition occurs, the SAS session terminates.

CONFIG System Option: UNIX

Specifies the configuration file that is used when initializing or overriding the values of SAS system options.

| Category: | Environment Control: Files |
| PROC OPTIONS GROUP= | ENVFILES |
| Default: | sasv9.cfg (see “Order of Precedence for Processing SAS Configuration Files” on page 27 ) |
| UNIX specifics: | all |
| Note: | This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference. |

Syntax

-CONFIG file-specification | –NOCONFIG

Required Arguments

-CONFIG file-specification
specifies a configuration file to be read. The file-specification must resolve to a valid UNIX filename.

-NOCONFIG
specifies that any previous CONFIG specification should be ignored and that the default system options should be used.

Details

Configuration files contain system option specifications that execute automatically whenever SAS is invoked.
Specifying a configuration file disables the default configuration file list.

See Also

“Customizing Your SAS Session By Using System Options” on page 21

DEVICE System Option: UNIX

Specifies a device driver for graphics output for SAS/GRAPH software.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SASV9_OPTIONS environment variable, SAS Viya: Not included

Category: Graphics: Driver Settings

PROC OPTIONS GROUP=GRAPHICS

Default: None

UNIX specifics: valid device drivers

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “DEVICE= System Option” in SAS/GRAPH: Reference

Syntax

-DEVICE device-driver-name

DEVICE=device-driver-name

Required Argument

device-driver-name specifies the name of a device driver for graphics output. The maximum number of characters for the device name is eight characters.

Details

To see the list of device drivers that are available under UNIX, you can use the GDEVICE procedure. If you are using the SAS windowing environment, submit the following statements:

    proc gdevice catalog=sashelp.devices;
    run;

If you are running SAS in interactive line mode or batch mode, submit the following statements:

    proc gdevice catalog=sashelp.devices nofs;
    list _all_;
    run;
See Also

SAS/GRAPH: Reference

---

**ECHO System Option: UNIX**

Specifies a message to be echoed to stdout.

Category: Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP= LOGCONTROL

Default: None

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference*.

### Syntax

```
-ECHO 'message' | -NOECHO
```

### Required Arguments

- **-ECHO 'message'** specifies the text of the message to be echoed to the computer. The text must be enclosed in single or double quotation marks if the message is more than one word. Otherwise, the quotation marks are not needed.

- **-NOECHO** specifies that no messages are to be echoed to the computer.

### Details

You can specify multiple ECHO options. The strings are displayed in the order in which SAS encounters them. See "How SAS Processes System Options That Are Set in Multiple Places" on page 24 for information about how that order is determined.

For example, you can specify the following code:

```
-echo 'SAS 9.4 under UNIX is initializing.'
```

The message appears in the Log window as SAS initializes.

### See Also

**System Options:**

- “ECHOAUTO System Option” in *SAS System Options: Reference*
EDITCMD System Option: UNIX

Specifies the host editor to be used with the HOSTEDIT command.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SASV9_OPTIONS environment variable, SAS Viya: Not included

Category: Environment Control: Display

PROC OPTIONS GROUP=

Default: None

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-EDITCMD "host-editor-pathname editor-options"
EDITCMD="host-editor-pathname editor-options"

Details

The EDITCMD system option specifies the command that is issued to the operating environment. If you are using a terminal-based editor, such as vi, you must specify a command that runs the editor inside a terminal emulator window.

You can define the EDITCMD option using the SASV9_OPTIONS environment variable as part of a configuration file or on the command line to make the definition available automatically to SAS. The option must be specified as a string in quotation marks. You can use either single or double quotation marks. You can change the value for the EDITCMD option during a SAS session by issuing an OPTIONS statement.

The host editor that you specify is used when you issue the HOSTEDIT command. The HOSTEDIT command is valid only when you are running SAS in a windowing environment.

If you do not specify the full pathname, SAS searches the pathnames specified in the $PATH environment variable. For example, to use vi, you would specify the following:

sas -editcmd "/usr/bin/X11/xterm -e /usr/bin/vi"

See Also

“Configuring SAS for Host Editor Support in UNIX Environments” on page 183
EMAILSYS System Option: UNIX

Specifies the email protocol to use for sending electronic mail.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SASV9_OPTIONS environment variable, SAS Viya: Not included

Category: Communications: Email

PROC
OPTIONS
GROUP=

Default: SMTP

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-EMAILSYS SMTP | name-of-script
EMAILSYS=SMTP | name-of-script

Required Arguments

SMTP
specifies the Simple Mail Transfer Protocol (SMTP) electronic mail interface.

ame-of-script
specifies which script to use for sending electronic mail from within SAS. Some external scripts do not support sending email attachments. These scripts are not supported by SAS.

Details

The EMAILSYS system option specifies which email protocol to use for sending electronic mail from within SAS. Specifying SMTP supports sending email attachments on UNIX, but might require changing the values of the EMAILHOST= and EMAILPORT= system options, depending on your site configuration.

You can set the EMAILSYS option at any time in your SAS session.

See Also

System Options:
- “EMAILHOST= System Option” in SAS System Options: Reference
- “EMAILPORT System Option” in SAS System Options: Reference

Other References:
ENGINE= System Option: UNIX

Specifies the default access method to use for SAS libraries.

Valid in: SAS 9.4: Configuration file, SAS invocation, SASV9_OPTIONS environment variable, SAS Viya: Not included

Category: Files: SAS Files

PROC OPTIONS GROUP=

Default: V9

UNIX specifics: valid values of engine-name

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “ENGINE= System Option” in SAS System Options: Reference

Syntax

-ENGINE engine-name

Required Argument

engine-name can be one of the following under UNIX:

BASE

V9

specifies the default SAS engine for SAS 9 through SAS 9.4 files.

V8

specifies the SAS engine for all SAS Version 9 files.

V7

specifies the SAS engine for all Version 7 files.

V6

specifies the SAS engine for Release 6.09 through Release 6.12. This engine is read-only.

See Also

“SAS Engines” in SAS Language Reference: Concepts
FILELOCKS System Option: UNIX

Specifies whether file locking is turned on or off and what action should be taken if a file cannot be locked.

Categories: Files: External Files
Files: SAS Files

PROC OPTIONS GROUP= ENVFILES, EXTFILES, SASFILES

Default: FAIL

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-FILELOCKS settingpath | pathsetting
-FILELOCKS NONE | FAIL | CONTINUE | RESET
FILELOCKS=(settingpath | pathsetting)
FILELOCKS=NONE | FAIL | CONTINUE | RESET

Required Arguments

setting
specifies the operating environment locking value for the specified path. The following values are valid:
- NONE
- FAIL
- CONTINUE
- RESET

path
specifies a path to a UNIX directory. Enclose the path in single or double quotation marks.

Tip The path argument can contain an environment variable.

NONE
turns file locking off. NONE specifies that SAS attempts to open the file without checking for an existing lock on the file. NONE does not place an operating system lock on the file. These files are not protected from shared Update access.
Tip  NONE does not suppress internal locking.

FAIL
turns file locking on. FAIL specifies that SAS attempts to place an operating
system lock on the file. Access to the file is denied if the file is already locked, or
if it cannot be locked. FAIL is the default value for FILELOCKS.

CONTINUE
turns file locking on. CONTINUE specifies that SAS attempts to place an
operating system lock on the file. If a file is already locked by someone else, an
attempt to open it fails. If the file cannot be locked for some other reason, the file
is opened and a warning message is sent to the log. For example, a file cannot
be locked if the file system does not support locking.

Tip  CONTINUE does not suppress internal locking.

RESET
specifies that all previous FILELOCKS settings are deleted, and resets the global
setting to the default value of FAIL. If you use the
FILELOCKS=(setting path|path setting) syntax, then RESET resets only
those files that are in path.

Details
The Basics of File Locking
In previous releases of SAS, the FILELOCKS system option was able to lock only
SAS files. In SAS 9.2 and later, the FILELOCKS system option is able to lock
external files as well.

The FILELOCKS system option enables you to lock both external files and SAS files
based on global settings that you set in the FILELOCKS system option. External file
locking applies to all files that are opened.

You can use multiple instances of the FILELOCKS option to establish different
settings for different paths. One path can be a subdirectory of another path. In this
case, the most specific matching path currently in effect governs operating system
file locking. The following example shows how you can specify multiple instances of
the FILELOCKS option in a configuration file:

    filelocks=('/u/myuserid/temp' NONE)
    filelocks=('/tmp' CONTINUE)

When the value of the FILELOCKS option is a set of path and setting, the path must
be enclosed in quotation marks. If you use FILELOCKS on the command line, then
quotation marks are not needed.

Note:  To prevent data corruption, setting FILELOCKS to NONE or CONTINUE is
not recommended.

Resetting Paths By Using the path and setting Arguments
The path and setting arguments enable you to apply a setting to a particular
directory and its subtrees. If you set the value of setting to RESET, then the path
and setting values are deleted.
For example, in the following case, filelocks=('/' reset), the current values for path and setting are deleted, and FILELOCKS resets the values to the following default: ('/' fail).

When FILELOCKS Is Set to FAIL

When FILELOCKS is set to FAIL (the default value), the following actions occur:

- SAS prevents two sessions from simultaneously opening the same SAS file for update or output.
- SAS prevents one session from reading a SAS file that another SAS session has open for update or output.
- SAS prevents one session from writing to a file that another SAS session has open in Read mode.

See Also

System Options:
- “WORKINIT System Option: UNIX” on page 463

---

**FILELOCKWAIT= System Option: UNIX**

Sets the number of seconds that SAS waits for a locked file to become available.

- **Valid in:** SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable
- **Category:** Files: SAS Files
- **PROC OPTIONS GROUP=** SASFILES
- **Default:** 0
- **Interaction:** The maximum value for FILELOCKWAIT= is based on the value of the FILELOCKWAITMAX= system option.
- **UNIX specifics:** all
- **Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference.*

**Syntax**

```
FILELOCKWAIT=wait-time
```

**Required Argument**

*wait-time*

specifies the amount of time, in seconds, that SAS waits for a locked file to become available.
Details

Normally, SAS returns an error if the file that it attempts to access is locked. With the FILELOCKWAIT= system option, you can limit the amount of time SAS waits for a locked SAS file to become available. When you set FILELOCKWAIT= to a value of wait-time, SAS waits the specified amount of time for the file to become available before failing. When the time limit is reached, SAS returns a locked-file error, and the DATA step fails. The maximum time that you can set to wait for a locked file is 600 seconds (10 minutes). When you set FILELOCKWAIT= to 0, SAS immediately fails.

The FILELOCKWAIT= option is used primarily by a system administrator, who can change the maximum value of FILELOCKWAIT= using the FILELOCKWAITMAX= system option. FILELOCKWAITMAX= sets a maximum value for the FILELOCKWAIT= option. The default maximum value is 600 seconds (10 minutes), but a system administrator can set the value to 300 seconds (5 minutes) or to any other value that is less than or equal to 600. Changing the value of FILELOCKWAITMAX= does not affect the value of FILELOCKWAIT=, it affects only the maximum value of FILELOCKWAIT=. The FILELOCKWAIT= option can be restricted by a system administrator.

FILELOCKWAIT= is both a system option and a LIBNAME option. The system option applies to all SAS I/O files. The LIBNAME option applies to the members in a library only. The LIBNAME option overrides the system option.

See Also

System Options:
- “FILELOCKS System Option: UNIX” on page 397
- “FILELOCKWAITMAX= System Option: UNIX” on page 400

FILELOCKWAITMAX= System Option: UNIX

Sets an upper limit on the time SAS waits for a locked file.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: Files: SAS Files

PROC OPTIONS GROUP=SASFILES

Default: 600

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

FILELOCKWAITMAX=wait-time
Required Argument

**wait-time**

specifies the amount of time, in seconds, that SAS waits for a locked file to become available.

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>600</td>
<td>0–600</td>
</tr>
</tbody>
</table>

**Interactions**

Specifying the FILELOCKWAITMAX= system option can have an adverse effect on one or more SAS/SHARE server and client sessions that are waiting for the release of a SAS file that is locked by another process. One or more wait conditions could lead to failed processes for a SAS/SHARE server and clients.

To prevent the possibility of a failed SAS/SHARE process, you can set FILELOCKWAITMAX=0. Setting this option cancels the amount of time that a SAS/SHARE server and clients would wait for the release of a locked file. Canceling the wait time would prevent a failed process.

**Details**

The FILELOCKWAITMAX= system option, if used with the FILELOCKWAIT= system option, enables you to set the maximum amount of time SAS waits for a locked file to become available before failing. If you do not use the FILELOCKWAIT= system option, then the value of FILELOCKWAITMAX= does not affect the wait time.

Normally, SAS returns an error if the file that it attempts to access is locked. If you use the FILELOCKWAIT= system option, SAS waits the specified number of seconds for the file to become available before failing. By default, the maximum value of FILELOCKWAIT= is 600 seconds.

A system administrator can change the maximum value using the FILELOCKWAITMAX= system option. Setting FILELOCKWAITMAX=0 effectively turns off the FILELOCKWAIT= option.

FILELOCKWAIT= is both a system option and a LIBNAME statement option. The system option applies to all SAS I/O files. The LIBNAME option applies to the members in a library only. The LIBNAME option overrides the system option. FILELOCKWAITMAX= is a system option only.

**See Also**

**System Options:**
- “FILELOCKS System Option: UNIX” on page 397
- “FILELOCKWAIT= System Option: UNIX” on page 399

**FMTSEARCH System Option: UNIX**

Specifies the order in which format catalogs are searched.
PROC
OPTIONS
GROUP=

Default: (WORK LIBRARY)

UNIX specifics: valid values for catalog-specification

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “FMTSEARCH= System Option” in SAS System Options: Reference

Syntax

-FMTSEARCH (catalog-specification-1 ... catalog-specification-n)

FMTSEARCH=(catalog-specification-1 ... catalog-specification-n)

Required Argument

catalog-specification

specifies the order in which format catalogs are searched until the desired member is found. The value of libref can be either libref or libref.catalog. If only the libref is given, SAS assumes that FORMATS is the catalog name.

Note: The value of libref must be in uppercase characters.

Details

To add additional catalog-specification entries, use the INSERT system option or the APPEND system option.

See Also

System Options:

- “APPEND= System Option” in SAS System Options: Reference
- “INSERT= System Option” in SAS System Options: Reference

FONTSLOC System Option: UNIX

Specifies the location of the SAS fonts that are loaded during the SAS session.

Category: Environment Control: Display
PROC OPTIONS GROUP=ENVDISPLAY, ODSPRINT

Default: !SASROOT/misc/fonts

UNIX specifics: valid pathname

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “FONTSLOC= System Option” in SAS System Options: Reference

Syntax

-FONTSLOC "directory-specification"

Required Argument

"directory-specification" specifies the directory that contains the SAS fonts that are loaded during the SAS session. The directory-specification must be enclosed in double quotation marks.

Details

The directory must be a valid operating environment pathname.

FULLSTIMER System Option: UNIX

Specifies whether to write all available system performance statistics and the datetime stamp to the SAS log.

Category: Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=LOGCONTROL

Default: NOFULLSTIMER

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-FULLSTIMER | -NOFULLSTIMER

FULLSTIMER | NOFULLSTIMER
Required Arguments

**FULLSTIMER**
writes to the SAS log a list of the host-dependent resources that were used for each step and for the entire SAS session. A datetime stamp is included in the output.

**NOFULLSTIMER**
does not write to the SAS log a complete list of resources or a datetime stamp.

Details

SAS uses UNIX system calls for your operating environment to get the statistical information from FULLSTIMER. The datetime stamp is listed in the output. You can change the behavior and format of the statistical information by using the STIMFMT system option.

Here is an example of FULLSTIMER output:

*Example Code 20.1  FULLSTIMER Output*

```
NOTE: PROCEDURE SQL used (Total process time):
   real time           0.01 seconds
   user cpu time       0.00 seconds
   system cpu time     0.00 seconds
   memory              5346.93k
   OS Memory           29868.00k
   Timestamp           10/18/2016 11:27:24 AM
Step Count                        59  Switch Count  44
Page Faults                       0
Page Reclaims                     11
Page Swaps                        0
Voluntary Context Switches        128
Involuntary Context Switches      0
Block Input Operations            0
Block Output Operations           264
```

Note: If both FULLSTIMER and STIMER system options are set, the FULLSTIMER statistics are written to the log.

FULLSTIMER displays the statistics defined in the following table.

*Table 20.1  Description of FULLSTIMER Statistics*

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real Time</td>
<td>the amount of real time (clock time) that is spent to process the SAS job. Real time is also referred to as elapsed time.</td>
</tr>
<tr>
<td>User CPU Time</td>
<td>the CPU time that is spent in the user program.</td>
</tr>
<tr>
<td>System CPU Time</td>
<td>the CPU time that is spent to perform operating system tasks (system overhead tasks) that support the execution of your SAS code.</td>
</tr>
<tr>
<td>Memory</td>
<td>the amount of memory required to run a step.</td>
</tr>
<tr>
<td>Statistic</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OS Memory</td>
<td>the largest amount of operating system memory that is available to SAS during the step.</td>
</tr>
<tr>
<td>Timestamp</td>
<td>the date and time that a step was executed.</td>
</tr>
<tr>
<td>Step Count</td>
<td>the count of DATA steps or procedures that run in a SAS program.</td>
</tr>
<tr>
<td>Switch Count</td>
<td>a count of task switches within a step—that is, within a DATA step or procedure—in a SAS program. A task switch occurs when a step requests service from another process. Another task switch occurs when the step resumes. The number reported is for the last step that runs.</td>
</tr>
<tr>
<td>Page Faults</td>
<td>the number of pages that SAS tried to access but were not in main memory and required I/O activity.</td>
</tr>
<tr>
<td>Page Reclaims</td>
<td>the number of pages that were accessed without I/O activity.</td>
</tr>
<tr>
<td>Page Swaps</td>
<td>the number of times a process was swapped out of main memory.</td>
</tr>
<tr>
<td>Voluntary Context Switches</td>
<td>the number of times that the SAS process had to pause because of a resource constraint such as a disk drive.</td>
</tr>
<tr>
<td>Involuntary Context Switches</td>
<td>the number of times that the operating system forced the SAS session to pause processing to allow other process to run.</td>
</tr>
<tr>
<td>Block Input Operations</td>
<td>the number of I/O operations that are performed to read the data into memory.</td>
</tr>
<tr>
<td>Block Output Operations</td>
<td>the number of I/O operations that are performed to write the data to a file.</td>
</tr>
</tbody>
</table>

For more information about these statistics, see the man pages for the `getrusage()` and `times()` UNIX system calls.

**Note:** Starting in SAS 9, some procedures use multiple threads. On computers with multiple CPUs, the operating system can run more than one thread simultaneously. Consequently, CPU time might exceed real time in your FULLSTIMER output. For example, a SAS procedure could use two threads that run on two separate CPUs simultaneously. The value of CPU time would be calculated as the following:

CPU1 time + CPU2 time = total CPU time
1 second + 1 second = 2 seconds
Because CPU1 can run a thread at the same time that CPU2 runs a separate thread for the same SAS process, you can theoretically consume 2 CPU seconds in 1 second of real time.

System Options:
- “STIMEFMT System Option: UNIX” on page 452
- “STIMER System Option: UNIX” on page 456

HELPHOST System Option: UNIX

Specifies the name of the host machine where the remote browser is to send Help and ODS output.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SASV9_OPTIONS environment variable, SAS Viya: Not included

Category: Environment Control: Help

PROC OPTIONS GROUP=HELP

Default: NULL

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “HELPHOST System Option” in SAS System Options: Reference

Syntax

HELPHOST="host"
-HELPHOST "host"

Required Argument

host

specifies the name of the computer where the remote browsing system is to be displayed. Quotation marks or parentheses are required. The maximum number of characters is 2048.

Details

If you do not specify the HELPHOST option, the remote browsing system is displayed on the host that is specified in the X display setting.
Examples:

Example 1: SAS Invocation

The syntax for specifying the HELPHOST system option for UNIX environments is shown in the following example:

```
sas94/helphost "my.computer.com"
```

Example 2: OPTIONS Statement: UNIX

The syntax for specifying the HELPHOST system option using the OPTIONS statement is shown in the following example:

```
options helphost="my.computer.com";
```

See Also

“Installing the Remote Browser Server” on page 150

HELPINDEX System Option: UNIX

Specifies one or more index files for the online SAS Help and Documentation.

- **Valid in:** SAS 9.4: Configuration file, SAS invocation, SAS Viya: Not included
- **Category:** Environment Control: Help
- **PROC OPTIONS GROUP=** HELP
- **Default:** /help/common.hlp/index.txt, /help/common.hlp/keywords.htm, common.hhk
- **UNIX specifics:** applet and HTML files must reside in the path specified by the HELPLOC option
- **Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

**Syntax**

```
HELPINDEX index-pathname-1 <index-pathname-2 <index-pathname-3>>
```

**Required Argument**

`index-pathname`

specifies the partial pathname for the index that is to be used by the online SAS Help and Documentation. The `index-pathname` argument can be any or all of the following:

`/help/applet-index-filename`

specifies the partial pathname of the index file that is to be used by the SAS Documentation Java applet in a UNIX environment. `applet-index-filename` must have a file extension of .txt, and it must reside in a path that is specified by the HELPLOC system option. The default is `/help/common.hlp/index.txt`. 
See the default index file for the format that is required for an index file.

/help/accessible-index-filename

specifies the partial pathname of an accessible index file that is to be used by the online SAS Help and Documentation in UNIX or z/OS environments. An accessible index file is an HTML file that can be used by web browsers. accessible-index-filename must have a file extension of .htm, and it must reside in a path that is specified by the HELPLOC system option. The default pathname is /help/common.hlp/keywords.htm.

See the default index file for the format that is required for an index file.

/HTML-Help-index-pathname

specifies the pathname of the Microsoft HTML Help index that is to be used by the online SAS Help and Documentation in SAS windowing environments. The default pathname is common.hhk. For information about creating an index for Microsoft HTML Help, see your Microsoft HTML Help documentation.

Details

Use the HELPINDEX option if you have a customized index that you want to use instead of the index that SAS supplies. If you use one configuration file to start SAS in more than one operating environment, you can specify all of the partial pathnames in the HELPINDEX option. The order of the pathnames is not important, although only one pathname of each type can be specified.

When the HELPINDEX option specifies a pathname for UNIX or z/OS, SAS determines the complete path by replacing /help/ in the partial pathname with the pathname specified in the HELPLOC option. If the HELPLOC option contains more than one pathname, SAS searches each path for the specified index.

For example, when the value of HELPINDEX is /help/common.hlp/myindex.htm and the value of HELPLOC is /u/myhome/myhelp, the complete path to the index is /u/myhome/myhelp/common.hlp/myindex.htm.

See Also

System Options:

- “HELPLOC System Option: UNIX” on page 408

HELPLOC System Option: UNIX

Specifies the location of the text and index files for the facility that is used to view the online SAS Help and Documentation.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Not included

Category: Environment Control: Help

PROC OPTIONS GROUP=

Default: !SASROOT/X11/native_help/en

UNIX specifics: default pathname
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

```
-HELPLOC (pathname <, pathname-2 ..., pathname-n>)
```

Required Argument

`pathname`

specifies one or more directory pathnames in which the online SAS Help and Documentation files are located.

Details

Specifying a value for the HELPLOC system option causes SAS to insert that value at the start of a list of concatenated values, the last of which is the default value. This behavior enables you to access help for your site without losing access to SAS Help and Documentation.

To add pathnames, use the INSERT or APPEND system options. For more information, see "INSERT System Option: UNIX" on page 412, and "APPEND System Option: UNIX" on page 382.

Example: Using the HELPLOC System Option

The following command contains two specifications of HELPLOC:

```
sas -insert helploc /app2/help -insert helploc /app1/help -append
```

The value of the system option is the following:

```
/app1/help, /app2/help, !SASROOT/X11/native_help
```

See Also

**System Options:**

- “APPEND= System Option” in SAS System Options: Reference
- “INSERT= System Option” in SAS System Options: Reference

---

**HELPTOC System Option: UNIX**

Specifies the table of contents files for the online SAS Help and Documentation.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Not included

Category: Environment Control: Help

PROC OPTIONS GROUP=

Default: /help/helpnav.hlp/config.txt, /help/common.hlp/toc.htm, common.hhc
UNIX specifics:
applet and HTML files must reside in the path specified by the HELPLOC option.

Note:
This option can be restricted by a site administrator. For more information, see "Restricted Options" in SAS System Options: Reference.

Syntax
-HELPTOC TOC-pathname-1 <TOC-pathname-2 <TOC-pathname-3>>

Required Argument

**TOC-pathname**
specifies a partial pathname for the table of contents that is to be used by the online SAS Help and Documentation. **TOC-pathname** can be any or all of the following:

/help/applet-TOC-filename
specifies the partial pathname of the table of contents file that is to be used by the SAS Documentation Java applet in a UNIX environment. The **applet-TOC-filename** must have a file extension of .txt, and it must reside in a path that is specified by the HELPLOC system option. The default is /help/helpnav.hlp/config.txt.

See the default table of contents file for the format that is required for an index file.

/help/accessible-TOC-filename
specifies the partial pathname of an accessible table of contents file that is to be used by the online SAS Help and Documentation in UNIX or z/OS environments. An accessible table of contents file is an HTML file that can be used by web browsers. The **accessible-TOC-filename** must have a file extension of .htm, and it must reside in a path that is specified by the HELPLOC system option. The default pathname is /help/common.hlp/toc.htm.

See the default table of contents file for the format that is required for a table of contents.

**HTML-Help-TOC-pathname**
specifies the complete pathname to the Microsoft HTML Help table of contents that is to be used by the online SAS Help and Documentation in windowing environments. The default pathname is common.hhc. For information about creating an index for Microsoft HTML Help, see your Microsoft HTML Help documentation.

Details

Use the HELPTOC system option if you have a customized table of contents that you want to use, instead of the table of contents that SAS provides. If you use one configuration file to start SAS in more than one operating environment, you can specify all of the partial pathnames in the HELPTOC option. The order of the pathnames is not important, although only one pathname of each type can be specified.

When the HELPTOC option specifies a pathname for UNIX or z/OS, SAS determines the complete path by replacing /help/ in the partial pathname with the pathname specified in the HELPLOC option. If the HELPLOC option contains more than one pathname, SAS searches each path for the table of contents.
For example, when HELPTOC is /help/common.hlp/mytoc.htm, and the value of HELPLOC is /u/myhome/myhelp, the complete path to the table of contents is /u/myhome/myhelp/common.hlp/mytoc.htm.

See Also

System Options:
- "HELPLOC System Option: UNIX" on page 408

HOSTINFOLOG System Option: UNIX

Specifies to write additional operating environment information in the SAS log when SAS starts.

Valid in:
- SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category:
Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=

Default:
HOSTINFOLOG

Note:
This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

HOSTINFOLOG | NOHOSTINFOLOG

Syntax Description

HOSTINFOLOG
specifies to write additional operating environment information in the SAS log when SAS starts.

NOHOSTINFOLOG
specifies to omit additional operating environment information in the SAS log when SAS starts.

Details

When HOSTINFOLOG is specified, SAS writes additional information about the operating environment to the SAS log.

See Also

System Options:
- “CPUID System Option” in SAS System Options: Reference
INSERT System Option: UNIX

Used when SAS starts; inserts the specified value at the beginning of the specified system option.

Category: Environment Control: Files

PROC

OPTIONS

GROUP= ENVFILES

Default: None

UNIX specifics: Configuration file, SAS command syntax

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “INSERT= System Option” in SAS System Options: Reference

Syntax

-INSERT system-option new-option-value

Required Arguments

system-option

- can be FMTSEARCH, HELPLOC, MAPS, MSG, SASAUTOS, SASHELP, SASSCRIPT, SET, AUTOEXEC, or CMPLIB

new-option-value

- is the new value that you want to insert at the beginning of the current value of system-option.

Details

By default, if you specify the AUTOEXEC, CMPLIB, FMTSEARCH, HELPLOC, MAPS, MSG, SASAUTOS, SASHELP, SASSCRIPT, or SET system option more than one time, the last value that is specified is the value that SAS uses. If you want to add additional pathnames to the pathnames already specified by one of these options, use the INSERT system option to add the additional pathnames. For example, if you enter the following SAS command, the only location in which SAS looks for help files is /apps/help. The output of PROC OPTIONS shows only /apps/help.

    sas -helploc /apps/help

If you want SAS to look in both the current path for help files and in /sas/help, looking first in /sas/help, then you must use the INSERT option.
If the current path for help files is `!SASROOT/X11/native_help`, then PROC OPTIONS now shows the following for the value of the HELPLOC option:

`('/sas/help' '!'SASROOT/X11/native_help')`

See Also

**System Options:**
- “APPEND System Option: UNIX” on page 382
- “APPEND= System Option” in SAS System Options: Reference

---

**JREOPTIONS System Option: UNIX**

Identifies the Java Runtime Environment (JRE) options for SAS.

**Valid in:** SAS 9.4: Configuration file, SAS invocation, SAS Viya: Not included

**Category:** Environment Control: Initialization and Operation

**PROC OPTIONS GROUP=** EXECMODES

**Default:** None

**UNIX specifics:** all

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

**CAUTION:** Changing Java options that affect SAS could cause SAS to not work. Before you change the settings for the JREOPTIONS option, contact SAS Technical Support to make sure that the Java setting that you want to change will not cause SAS to fail. A best practice is to change only the Java properties for your own Java code.

**Syntax**

```
-JREOPTIONS (-JRE-option-1 <-JRE-option-n>)
```

**Required Argument**

```
-JRE-option
```

specifies one or more JRE options.

JRE options must begin with a hyphen (-). Use a space to separate multiple JRE options. Valid values for **JRE-option** depend on your installation's JRE. For information about JRE options, see your installation's Java documentation.

**Details**

JRE options must be enclosed in parentheses. If you issue JREOPTIONS options on the command line, then you must put a backslash (`\`) before the open parenthesis.
and close parenthesis, as shown in the examples below. If you specify multiple JREOPTIONS options, then SAS appends JRE options to JRE options that are currently defined. Incorrect JRE options are ignored.

Example: Using JRE Options

- jreoptions \{-Dmy.java.property\}
- jreoptions \{-Xmx512m -Xms256m\}

LINESIZE System Option: UNIX

Specifies the line size of the SAS Log and Output windows.

Valid in:

SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

Categories:

Log and Procedure Output Control: SAS Log and Procedure Output
Log and Procedure Output Control: SAS Log
Log and Procedure Output Control: Procedure Output

PROC OPTIONS GROUP= LISTCONTROL, LOG_LISTCONTROL, LOGCONTROL

Default:

the display width setting for interactive modes; 132 for batch mode

UNIX specifics:

default values

Note:

This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See:

“LINESIZE= System Option” in SAS System Options: Reference

Syntax

- LINESIZE n | hexX | MIN | MAX
LINESIZE=n | hexX | MIN | MAX

Required Arguments

n
specifies the line size in characters. Valid values range between 64 and 256.

hexX
specifies the line size as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx specifies 45 characters.

MIN
sets the line size to 64 characters.

MAX
sets the line size to 256 characters.
LOG System Option: UNIX

Specifies a destination for the SAS log when running in batch mode.

Category: Environment Control: Files

PROC
OPTIONS
GROUP= ENVFILES

Default: a file in the current directory with the same filename as the SAS source file and an extension of .log

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-LOG file-specification | -NOLOG

Required Arguments

-LOG file-specification

specifies the destination for the SAS log. The file-specification can be any valid UNIX path to a directory, a filename, or an environment variable that is associated with a path. If you specify only the path to a directory, the log file is created in the specified directory. The default name for this file is filename.log, where filename is the name of your SAS job.

-NOLOG

suppresses the creation of the SAS log. Do not use this value unless your SAS program is thoroughly debugged.

Details

The LOG system option specifies a destination for the SAS log when running in batch mode. The LOG system option is valid in batch mode; it is ignored in interactive modes.

Using directives in the value of the LOG system option enables you to control when logs are open and closed and how they are named, based on real-time events such as time, month, day of week, and so on. For a valid list of directives, see "LOGPARM= System Option" in SAS System Options: Reference.

If you start SAS in batch mode or server mode and the LOGCONFIGLOC= option is specified, logging is performed by the SAS logging facility. The traditional SAS log option LOGPARM= is ignored. The traditional SAS log option LOG= is honored only
when the %S{App.Log} conversion character is specified in the logging
configuration file. For more information, see the SAS Logging Facility in SAS
Logging: Configuration and Programming Reference.

Note: When SAS is started with the OBJECTSERVER and NOTERMINAL system
options and no log is specified, SAS discards all log and alternate log messages.

See Also

System Options:

- “LOGPARM= System Option” in SAS System Options: Reference

Other References:

- “Using SAS System Options to Route Output” on page 116

LPTYPE System Option: UNIX

Specifies which UNIX command and option settings are used to route files to the printer.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options
window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement,
SASV9_OPTIONS environment variable

Category: Log and Procedure Output Control: Procedure Output

PROC
OPTIONS
GROUP=

Default: None

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see
“Restricted Options” in SAS System Options: Reference.

Syntax

-LPTYPE BSD | SYSV
LPTYPE=BSD | SYSV

Required Arguments

BSD

causes SAS to use the lpr command to send files to the printer. The lpr
command is usually supported on UNIX operating systems, such as HP-UX, that
were developed at the University of California, Berkeley.
SYSV
causes SAS to use the \texttt{lp} command to send files to the printer. The \texttt{lp} command is usually supported on operating systems derived from UNIX System V, such as Solaris.

Details
The LPTYPE option determines whether SAS is to use the \texttt{lpr} or the \texttt{lp} UNIX command to print files.

If you do not know whether to specify BSD or SYSV, check with your system administrator.

By default, SAS uses the \texttt{lpr} command if your operating system is derived from Berkeley's version. Otherwise, it uses the \texttt{lp} command.

See Also

System Options:

- “PRINTCMD System Option: UNIX” on page 432

MAPS System Option: UNIX
Specifies the name of the SAS library containing the SAS/GRAPH map data sets.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Not included

Category: Graphics: Driver Settings

PROC OPTIONS GROUP=

Default: !SASROOT/maps (set in the installed !SASROOT/sasv9.cfg file)

UNIX specifics: default value and location-of-maps

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “MAPS= System Option” in SAS/GRAPH and Base SAS: Mapping Reference

Syntax

- \texttt{-MAPS} location-of-maps
- \texttt{MAPS=} location-of-maps

Required Argument

\textit{location-of-maps}
specifies a libref, a valid UNIX pathname, or an environment variable associated with a pathname. Do not use a specific filename.
Details

The Basics

You can reassign the MAPS libref, but you cannot clear it.

Map files might have to be uncompressed before they are used. Use the CONTENTS statement in the DATASETS procedure to determine whether they are compressed.

Inserting and Appending Pathnames

By default, if you specify the MAPS system option more than one time, the last option that is specified is the option value that SAS uses.

If you want to add additional pathnames to the pathnames already specified by the MAPS system option, use the INSERT system option to add the additional pathnames. For example, if you enter the following SAS command, the only location in which SAS looks for help files is /apps/help. The output of PROC OPTIONS shows only /apps/help.

sas -helploc /apps/help

If you want SAS to look in both the current path for help files, and in /sas/help, and if you want SAS to look first in /apps/help, then you must use the INSERT option.

sas -insert helploc /apps/help

If you want SAS to look first in /sas/help, and then in /apps/help, then you must use the APPEND option.

sas -helploc /sas/help -append helploc /apps/help

If the current path for help files is $SASROOT/X11/native_help, then PROC OPTIONS now shows the following for the value of the HELPLOC option:

('/apps/help' '$SASROOT/X11/native_help')

System Options:

- "APPEND= System Option" in SAS System Options: Reference
- "INSERT= System Option" in SAS System Options: Reference

MAXMEMQUERY System Option: UNIX

Specifies the maximum amount of memory that can be allocated per request for certain procedures.

Category: System Administration: Memory

PROC OPTIONS GROUP= MEMORY
Syntax

-\texttt{MAXMEMQUERY} \( n \) | \( nK \) | \( nM \) | \( nG \) | \texttt{hexX} | \texttt{MIN} | \texttt{MAX}

\texttt{MAXMEMQUERY=}\( n \) | \( nK \) | \( nM \) | \( nG \) | \texttt{hexX} | \texttt{MIN} | \texttt{MAX}

Required Arguments

\( n \) | \( nK \) | \( nM \) | \( nG \)

specifies the limit in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 bytes, a value of \( .782k \) specifies 801 bytes, and a value of 3m specifies 3,145,728 bytes.

\texttt{hexX}

specifies the amount of memory as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx sets the amount of memory to 45 bytes.

\texttt{MIN}

specifies 0 bytes, which indicates that there is no limit on the total amount of memory that can be allocated per request by each SAS procedure. These memory allocations are limited by the value of MEMSIZE.

\texttt{MAX}

specifies a limit to the amount of memory that is allocated. Memory allocations (9,007,199,254,740,992 byte limit on 64-bit machines) are limited by the value of MEMSIZE.

Details

Some SAS procedures use the \texttt{MAXMEMQUERY} option to specify the largest block of virtual memory that a procedure can request at one time. By contrast, the MEMSIZE option places a limit on the total amount of virtual memory that SAS dynamically allocates at any time. This virtual memory is supported by a combination of real memory and paging space. The operating environment begins paging when the amount of virtual memory that is required exceeds the real memory that is available. To prevent paging and the associated performance problems, the \texttt{MAXMEMQUERY} and MEMSIZE system options should be set to a subset of real memory.
MEMSIZE System Option: UNIX

Specifies the limit on the total amount of virtual memory that can be used by a SAS session.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Categories: System Administration: Memory
System Administration: Performance

PROC OPTIONS
GROUP=MEMORY, PERFORMANCE

Default: 2G

Restriction: This system option is not valid for the CAS server.

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-MEMSIZE n | nK | nM | nG | nT | hexX | MAX

Required Arguments

n | nK | nM | nG | nT
specifies the limit in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); 1,073,741,824 (gigabytes); or 1,099,511,627,776 (terabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes (for example, a value of .25G specifies 268,435,456 bytes).

Note: You can also specify the KB, MB, or GB syntax notations.

hexX
specifies the amount of memory as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 0F00000X sets the value of the MEMSIZE option to 15,728,640 bytes. A value of 0x is equivalent to using the MAX value.

MAX
specifies to set the memory size to the largest reasonable value depending on the amounts of physical memory and paging space that are available when SAS is started.
Details

The Basics

The MEMSIZE system option limits the total amount of memory that is available to each SAS session. It places an enforced limit on the amount of virtual memory that SAS can dynamically allocate at execution. If MEMSIZE is set too low, your jobs can fail, and errors appear in the SAS log indicating that insufficient memory was available. By contrast, the REALMEMSIZE and MAXMEMQUERY system options, the SORTSIZE= option in the SORT procedure, and the SUMSIZE= option in the SUMMARY procedure all provide for procedure tuning.

When you start a SAS session, if the value of MEMSIZE is larger than the amount of virtual memory that is available for a process, then you are notified in the SAS log. If this occurs, adjust the value of MEMSIZE so that it is smaller than the amount of virtual memory or use the MAX value. The MAX value automatically considers both page size and virtual memory limit and adjusts the MEMSIZE value accordingly. You can use the limit, ulimit --a, or ulimit --aS command to see the amount of virtual memory that is available for your user ID.

If you specify an unreasonably small value for MEMSIZE (for example, 6K), then the MEMSIZE value automatically increases to the minimum value that enables SAS to start.

Numeric values in excess of 9,223,372,036,854,775,807 bytes are rejected as invalid and prevent SAS from starting.

SAS does not automatically reserve or allocate the amount of virtual memory that you specify in the MEMSIZE system option. SAS uses only as much memory as it needs to complete a process. For example, a DATA step might require only 20 MB of memory, so even though MEMSIZE is set to 500 MB, SAS uses only 20 MB of memory. While your SAS jobs are running, you can monitor the effects of larger memory settings by using system monitoring tools, such as VMSTAT and the top tool. With some tools, address space might be allocated to memory, but pages might not be assigned to that memory. These tools report a higher value than real memory actually used. When a user invokes third-party software, such as database vendor code that SAS loads, the memory allocations for that third-party software are not controlled by MEMSIZE. Third-party software memory usage can be reported by the top tool.

Setting the Size of MEMSIZE

Setting MEMSIZE=MAX sets MEMSIZE to 80% of physical memory. Setting MEMSIZE to MAX is the same as setting MEMSIZE to 0. Setting MEMSIZE to MAX is reasonable only if no processes that consume large amounts of memory are likely to become active after SAS has started. For example, if multiple instances of SAS are running concurrently, and all of the sessions were started with a MEMSIZE value of MAX, then one or more of these sessions can encounter out-of-memory conditions, or the operating system can run out of available paging space. MEMSIZE=MAX calculates a value that would help prevent the system from paging if all of the memory were allocated.

The optimal setting for this option depends on the other applications that are running and the system resources available at your site. The amount of memory available to SAS processes can also be limited by your system administrator.

If you set MEMSIZE to the maximum amount of memory that is reasonably attainable, some procedures scale themselves to the available memory. To determine the limit on the total amount of memory to be used by SAS, you can issue a PROC OPTIONS statement:
proc options option=memsizel;
run;

Setting MEMSIZE to 0 is used as a test that can determine a good value to set for MEMSIZE.

To determine the optimal setting of MEMSIZE, execute a SAS procedure or DATA step with the FULLSTIMER option and MEMSIZE set to 0. Note the amount of memory that is used by the process, and then set MEMSIZE to a larger amount.

Comparisons

Some SAS procedures use the REALMEMSIZE system option to specify how much real memory the procedure can allocate and use without inducing excessive page swapping. By contrast, the MEMSIZE system option places a limit on the total amount of virtual memory that SAS dynamically allocates at any time. This virtual memory is supported by a combination of real memory and paging space.

The operating environment begins paging when the amount of virtual memory that is required exceeds the real memory that is available. To prevent paging and the associated performance problems, the REALMEMSIZE and MEMSIZE system options should be set to a subset of real memory.

System Options:
- "REALMEMSIZE System Option: UNIX" on page 433

Procedures:
- Chapter 31, "SORT Procedure," on page 507

MSG System Option: UNIX

Specifies the library that contains the SAS error messages.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: Environment Control: Files

PROC OPTIONS GROUP= ENVFILES

Alias: SASMSG

Default: !SASROOT/sasmsg (set in the installed !SASROOT/sasv9.cfg file)

Note: This option can be restricted by a site administrator. For more information, see "Restricted Options" in SAS System Options: Reference.
Syntax

-MSG pathname
-MSG ('pathname' 'pathname' ...)  

Required Argument

pathname must resolve to a valid UNIX pathname. You can use an environment variable that resolves to a valid pathname.

Details

The MSG system option specifies the library that contains the SAS error messages. This option is set during the installation process and is not normally changed after installation.

To add additional pathnames, use the INSERT or APPEND system options. For more information, see "INSERT System Option: UNIX" on page 412, and "APPEND System Option: UNIX" on page 382.

See Also

MSGCASE System Option: UNIX

Specifies whether notes, warnings, and error messages that are generated by SAS are displayed in uppercase characters.

Valid in:
- SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category:
- Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=
- LOGCONTROL

Default:
- NOMSGCASE

UNIX specifics:
- all

Note:
- This option can be restricted by a site administrator. For more information, see "Restricted Options" in SAS System Options: Reference.

Syntax

-MSGCASE | -NOMSGCASE
Required Arguments

- **MSGCASE**
  displays notes, warnings, and error messages in uppercase characters.

- **NOMSGCASE**
  displays notes, warnings, and error messages in uppercase and lowercase characters.

**Details**

The MSGCASE system option specifies whether notes, warnings, and error messages that are generated by SAS are displayed in uppercase characters. User-generated messages and source lines are not affected by the MSGCASE system option.

MSGCASE is supported in NL formats. For information about NL formats, see [SAS National Language Support (NLS): Reference Guide](#).

---

**MSYMTABMAX System Option: UNIX**

Specifies the maximum amount of memory available to the macro variable symbol tables.

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Category:</td>
<td>Macro: SAS Macro</td>
</tr>
<tr>
<td>PROC OPTIONS GROUP=</td>
<td>MACRO</td>
</tr>
</tbody>
</table>

**Default:**

4M (set in the installed !SASROOT/sasv9.cfg file)

**UNIX specifics:**

default value

**Note:**

This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in [SAS System Options: Reference](#).

**See:**

MSYMTABMAX= System Option in [SAS Macro Language: Reference](#)

---

**Syntax**

**-MSYMTABMAX**  \( n \ | \ nK \ | \ nM \ | \ nG \ | \ hexX \ | \ MIN \ | \ MAX \\
MSYMTABMAX=\( n \ | \ nK \ | \ nM \ | \ nG \ | \ hexX \ | \ MIN \ | \ MAX \)

**Required Arguments**

\( n \ | \ nK \ | \ nM \ | \ nG \)

specifies the maximum amount of memory that is available in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 bytes, a value of .782k specifies 801 bytes, and a value of 3m specifies 3,145,728 bytes.
Note: You can also specify the KB, MB, or GB syntax notations.

hexX specifies the maximum amount of memory that is available as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx sets the maximum amount of memory to 45 bytes.

MIN sets the amount of memory that is available to the minimum setting, which is 0 bytes. Setting the amount of memory to the minimum setting causes all macro symbol tables to be written to disk.

MAX sets the amount of memory that is available to the maximum setting. On 64-bit computers, this value is 9,007,199,254,740,992 bytes.

**MVARSIZE System Option: UNIX**

Specifies the maximum size for in-memory macro variables.

**Valid in:**
- SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

**Category:**
- Macro: SAS Macro

**PROC OPTIONS GROUP=**
- MACRO

**Default:**
- 65534

**UNIX specifics:**
- default value

**Note:**
- This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference*.

**See:**
- MVARSIZE System Option in *SAS Macro Language: Reference*

**Syntax**

```
-MVARSIZE n | nK | nM | nG | hexX | MIN | MAX
MVARSIZE=n | nK | nM | nG | hexX | MIN | MAX
```

**Required Arguments**

```
n | nK | nM | nG
```

specifies the maximum macro variable size in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 bytes, a value of \( .782k \) specifies 801 bytes, and a value of \( 3m \) specifies 3,145,728 bytes.
Note: You can also specify the KB, MB, or GB syntax notations.

**hexX**
Specifies the maximum macro variable size as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, 2dx sets the maximum macro variable size to 45 bytes.

**MIN**
Sets the macro variable size to the minimum setting, which is 0 bytes. Setting the macro variable size to the minimum setting causes all macro variable values to be written to disk.

**MAX**
Sets the macro variable size to the maximum setting, which is 65,534 bytes.

---

**NEWS System Option: UNIX**

Specifies a file that contains messages to be written to the SAS log.

**Valid in:** SAS 9.4: Configuration file, SAS invocation, SASV9_OPTIONS environment variable, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

**Category:** Environment Control: Files

**PROC OPTIONS GROUP=** ENVFILES, LOGCONTROL

**Default:** !SASROOT/misc/base/news (set in the installed !SASROOT/sasv9/cfg file)

**UNIX specifics:** -NONEWS option

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

**See:** “NEWS= System Option” in SAS System Options: Reference

---

**Syntax**

-NEWS file-specification | -NONEWS

**Required Arguments**

-NEWS file-specification
  Specifies an external file. This file contains the messages for the SAS log.

-NONEWS
  Specifies that the contents of the NEWS file are not displayed in the SAS log, even if the file exists. This option causes any previous NEWS specifications to be ignored.

**Details**

The contents of the NEWS file are displayed in the SAS log immediately after the SAS header.
OBS= System Option: UNIX

Specifies the last observation that SAS processes in a data set.

Category: Files: SAS Files

PROC OPTIONS GROUP=SASFILES

Default: MAX

Interaction: SAS Studio sets OBS=MAX before each code submission. For more information, see “System Options in SAS Studio” in SAS System Options: Reference.

UNIX specifics: default value

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “OBS= System Option” in SAS System Options: Reference

Syntax

-OBS n | nK | nM | nG | nT | hexX | MIN | MAX

OBS=n | nK | nM | nG | nT | hexX | MIN | MAX

Required Arguments

n | nK | nM | nG | nT

specifies a number to indicate when to stop processing. Using one of the letter notations results in multiplying the integer by a specific value. That is, specifying K (kilo) multiplies the integer by 1,024, M (mega) multiplies by 1,048,576, G (giga) multiplies by 1,073,741,824, or T (tera) multiplies by 1,099,511,627,776.

You can specify a decimal value for n when it is used to specify a K, M, G, or T value. For example, a value of 20 specifies 20 observations or records, a value of .782k specifies 801 observations or records, and a value of 3m specifies 3,145,728 observations or records.

Note: You can also specify the KB, MB, GB, or TB syntax notations.

hexX

specifies a number as a hexadecimal value to indicate when to stop processing. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the hexadecimal value F8 must be specified as 0F8x in order to specify the decimal equivalent of 248. For example, the value 2dx specifies the decimal equivalent of 45.
MIN
sets the number to 0 to indicate when to stop processing.

If OBS=0 and the NOREPLACE option is in effect, SAS might still be able to take
certain actions. For more information, see “OBS= System Option” in SAS
System Options: Reference.

MAX
sets the number 9,223,372,036,854,775,807 to indicate when to stop
processing.

OPLIST System Option: UNIX

Specifies whether the settings of the SAS system options are written to the SAS log.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS
invocation, SASV9_OPTIONS environment variable

Category: Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=

Default: NOOPLIST

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see
“Restricted Options” in SAS System Options: Reference.

Syntax

-OPLIST | -NOOPLIST

Details

The OPLIST system option echoes only the system options specified on the
command line. It does not echo any system options specified in the configuration file
or in the SASV9_OPTIONS environment variable. (If you want to echo the contents
of the configuration file, use the VERBOSE option.) For example, invoke SAS with
the following command:

    sas -nodms -fullstimer -nonews -oplist

SAS writes this line to the SAS log:

    NOTE: SAS command line: -nodms -fullstimer -nonews -oplist

Password values that are provided for system options (such as EMAILPW,
METAPASS, or PDFOPENPW) are automatically masked in the SAS log. For
example, suppose that you invoke SAS with the following command:

    sas -nodms -oplist -emailpw foo -metapass xyz -pdfopenpw foobar -stimer

The command is displayed in the log as follows:
PAGESIZE= System Option: UNIX

Specifies the number of lines that compose a page of SAS output.

Categories: Log and Procedure Output Control: SAS Log and Procedure Output
Log and Procedure Output Control: SAS Log
Log and Procedure Output Control: Procedure Output

PROC OPTIONS
GROUP=

Default: number of lines on your display for interactive modes; 60 for batch mode

UNIX specifics: default values and range

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “PAGESIZE= System Option” in SAS System Options: Reference

Syntax

-PAGESIZE n | nK | hexX | MIN | MAX

PAGESIZE= n | nK | hexX | MIN | MAX

Required Arguments

n | nK

specifies the number of lines that compose a page in multiples of 1 (n) or 1,024 (nK). You can specify decimal values for the number of kilobytes. For example, a value of 800 specifies 800 lines, a value of .782k specifies 801 lines, and a value of 3k specifies 3,072 lines.

Note: You can also specify the KB syntax notation.
**hexX**

specifies the number of lines that compose a page as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the value 2dx specifies 45 lines.

**MIN**

sets the number of lines that compose a page to the minimum setting, which is 15.

**MAX**

sets the number of lines that compose a page to the maximum setting, which is 32,767.

**Details**

The default for interactive modes is the number of lines on your display. For batch mode, the default is 60.

**See Also**

- “Controlling the Content and Appearance of Output in UNIX Environments” on page 118

---

### PATH System Option: UNIX

Specifies one or more search paths for SAS executable files.

**Valid in:**

SAS 9.4: Configuration file, SAS invocation, SASV9_OPTIONS environment variable,
SAS Viya: Not included

**Category:**

Environment Control: Files

**PROC OPTIONS GROUP=**

ENVFILES

**Default:**

!SASROOT/sasexe (set in the installed !SASROOT/sasv9/cfg file)

**UNIX specifics:**

all

**Note:**

This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

---

**Syntax**

- **PATH directory-specification**

**Required Argument**

*directory-specification*

specifies the search path for SAS executable files.
Details

The PATH system option identifies the search paths for SAS executable files. You can specify multiple PATH options to define the search order. The paths are searched in the order in which SAS encounters them. Therefore, specify at the beginning of the list the paths for the products that you run most frequently. For information about how that order is determined when you specify the PATH system option more than once, see "How SAS Processes System Options That Are Set in Multiple Places" on page 24.

PRINT System Option: UNIX

Specifies a destination for SAS output when running in batch mode.

Category: Environment Control: Files

PROC OPTIONS GROUP= ENVFILES

Default: the SAS output from a batch SAS program is written to a file in the current directory with the same filename as the SAS source file, with an extension of .lst

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-PRINT file-specification | -NOPRINT

Required Arguments

-PRINT file-specification

specifies the location for the SAS procedure output file. The file-specification can be any valid UNIX path to a directory, a filename, or an environment variable that is associated with a path. If you specify only the path to a directory, the procedure output file is created in the specified directory. The default name for this file is filename.lst, where filename is the name of your SAS job.

-NOPRINT

suppresses the creation of the SAS procedure output file.

Details

The PRINT system option specifies a destination for SAS output when running in batch mode. The PRINT system option is valid in batch mode; it is ignored in interactive modes.
PRINTCMD System Option: UNIX

Specifies the print command that SAS uses.

Valid in:
- SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

Category:
- Log and Procedure Output Control: Procedure Output

PROC
OPTIONS
GROUP=

Default: None

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-PRINTCMD "print-command"

PRINTCMD="print-command"

Required Argument

print-command

specifies the options that you can use with PRINTCMD.

Details

The syntax of the options passed to the print command is controlled by the LPTYPE system option. If LPTYPE is set to BSD, the command uses lpr command options. If LPTYPE is set to SYSV, the command uses lp command options.

If your site uses a print command (spooler) other than lp or lpr, print-command specifies its name. The PRINTCMD option overrides the LPTYPE setting.

When specified in an OPTIONS statement, the PRINTCMD option does not change the print commands assigned to previously defined filenames. For example, consider the following code:

```sas
filename pcl printer;
proc printto print=pcl;
run;
proc print data=sales.week;
run;

options printcmd="netlp";
```
filename pc2 printer;
proc printto print=pc2;
run;
proc print data=sales.month;
run;

Output associated with PC2 uses the netlp command; output associated with PC1 uses the default print command.

Other References:

- “Overview of Printing Output in UNIX Environments” on page 104

REALMEMSIZE System Option: UNIX

Specifies the amount of real (physical) memory SAS can expect to allocate.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: System Administration: Memory

PROC OPTIONS GROUP=

MEMORY

Default: 0

UNIX specifics: valid values

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-REALMEMSIZE n | nK | nM | nG | hexX | MIN | MAX

Required Arguments

n | nK | nM | nG

specifies the amount of memory to reserve in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes), or 1,073,741,824 (gigabytes). The value of n can be a decimal value. For example, a value of 8 specifies 8 bytes, a value of .782k specifies 801 bytes, and a value of 3m specifies 3,145,728 bytes.

Note: You can also specify the KB, MB, or GB syntax notations.
**hexX**
specifies the amount of memory as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the value 2dx sets the amount of memory to 45 bytes.

**MIN**
specifies a value of 0, which indicates that the memory usage is determined by SAS when SAS starts.

**MAX**
specifies to set the memory size to the largest permissible value. This value depends on the system limit.

**Details**

**The Basics**
The REALMEMSIZE system option sets a recommended upper limit on real memory for procedures that can use both real memory and utility disk space, such as PROC SUMMARY and PROC SORT. This upper limit helps avoid virtual memory thrashing.

The REALMEMSIZE option should never be set above the amount of real memory. If the amount of real memory is insufficient for a job to run, then setting the MEMSIZE option above the amount of real memory might enable the job to run using a combination of real and virtual memory.

**Comparisons**
Some SAS procedures use the REALMEMSIZE system option to specify how much real memory the procedure can allocate and use without inducing excessive page swapping. By contrast, the MEMSIZE system option places a limit on the total amount of virtual memory that SAS dynamically allocates at any time. This virtual memory is supported by a combination of real memory and paging space.

The operating environment begins paging when the amount of virtual memory that is required exceeds the real memory that is available. To prevent paging and the associated performance problems, the REALMEMSIZE and MEMSIZE system options should be set to a subset of real memory.

**See Also**

**System Options:**
- “MEMSIZE System Option: UNIX” on page 420

**Procedures:**
- Chapter 31, “SORT Procedure,” on page 507

---

**RSASUSER System Option: UNIX**
Controls whether members of the Sasuser library can be opened for update or for Read-Only access.
**Valid in:** SAS 9.4: Configuration file, SAS invocation, SASV9_OPTIONS environment variable, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

**Category:** Environment Control: Files

**PROC OPTIONS GROUP= ENVFILES**

**Default:** NORSASUSER

**UNIX specifics:** network considerations

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference*.

**See:** “RSASUSER System Option” in *SAS System Options: Reference*

---

**Syntax**

- **-RSASUSER | -NORSASUSER**

**Required Arguments**

- **-RSASUSER**
  
  limits access to the Sasuser library to Read-Only access.

- **-NORSASUSER**
  
  prevents users from sharing members of the Sasuser library because it allows a user to open a file in the Sasuser library for Update access. Update access requires exclusive rights to the library member.

**Details**

If the Sasuser library is being shared by multiple users or the same user is running SAS multiple times simultaneously, the Sasuser library is often shared. By default, if one user has a member of the Sasuser library open for update, all other users are denied access to that SAS library member. For example, if one user is writing to the Sasuser.Profile catalog, no other user can even read data from the Profile catalog.

Specifying RSASUSER enables a group of users to share Sasuser library members by allowing all users Read-Only access to members. In the Profile catalog example, if RSASUSER is in effect, all users can open the Profile catalog for Read-Only access, allowing other users to concurrently read from the Profile catalog. However, no user can write information out to the Profile catalog; you receive an error message if you try to do so.

Specifying RSASUSER from the command line affects only that session's access to files. To enable a group of users to share members in the Sasuser library, the system manager should set RSASUSER in a common SAS configuration file. This configuration file should be shared by all users that share the Sasuser library.

If you specify RSASUSER but no Profile catalog exists in the Sasuser library, the Profile catalog is created in the Work library.

---

**Note:** The RSASUSER option is extremely useful for sharing information (such as the Profile catalog) stored in the Sasuser library. It is less practical when used in
conjunction with SAS/ASSIST software or other SAS modules that require Update access to the Sasuser library.

See Also

“Sharing SAS Files in a UNIX Environment” on page 50

RTRACE System Option: UNIX

Produces a list of resources that are read or loaded during a SAS session.

Category: Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP= LOGCONTROL

Default: None

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-RTRACE ALL | NONE | VER

Required Arguments

ALL
produces a list of resources that are read or loaded during a SAS session.

NONE
turns off RTRACE on all files.

VER
writes the version number and other trace information for each module that SAS loads.

Details

The RTRACE system option produces a list of resources that are read or loaded during the execution of SAS. If you specify -RTRACE ALL but do not specify the RTRACELOC system option, the output is written to the SAS log.

See Also

System Options:

“RTRACELOC System Option: UNIX” on page 437
RTRACELOC System Option: UNIX

Specifies the pathname of the file to which the list of resources that are read or loaded during a SAS session is written.

Category: Environment Control: Files

PROC OPTIONS GROUP= ENVFILES

Default: None

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Tip: You can expand the RTRACELOC filename when %p (PID), %d (date), or %t (time) are specified.

Syntax

-RTRACELOC pathname

RTRACELOC=pathname

Required Argument

pathname

specifies the file to which RTRACE information is written. The pathname must include the path and the filename for the RTRACE output.

You can expand the output filename to include the process ID, date, or time in the filename by specifying %p, %d, or %t, respectively. The system date is included in the filename in the YYYYMMDD (year, month, day) format. The time is included in the filename formatted as HHMMSSmmm (hours, minutes, seconds, milliseconds). For example, to include the date, time, and process ID in the filename, you can specify the following options:

-rtrace all -rtraceloc mytrace.%d.%t.%p

This results in a filename similar to mytrace.20140306.125510942.3808.

Details

The RTRACELOC system option specifies the pathname of the file to which RTRACE information is written. If the pathname does not include a filename, the output is directed to standard output. If you specify -RTRACE ALL, but do not specify the RTRACELOC system option, the output is written to the SAS log.

**System Options:**
- “RTRACE System Option: UNIX” on page 436

---

### SASAUTOS System Option: UNIX

Specifies the autocall library.

**Valid in:**
- SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

**Categories:**
- Environment Control: Files
- Macro: SAS Macro

**PROC OPTIONS GROUP=**

**Default:** SASAUTOS fileref

**UNIX specifics:** syntax for specifying multiple *directory-specifications*

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference*.

**See:** “SASAUTOS= Macro System Option” in *SAS Macro Language: Reference*

---

### Syntax

```
-SASAUTOS 'directory-specification' | fileref
-SASAUTOS ('directory-specification-1' | fileref-1, ..., 'directory-specification-n' | fileref-n)
-NOSASAUTOS
SASAUTOS='directory-specification' | fileref
SASAUTOS=('directory-specification-1' | fileref-1, ..., 'directory-specification-n' | fileref-n)
NOSASAUTOS
```

**Required Arguments**

*directory-specification*
- specifies a pathname to an autocall macro library.

*fileref*
- specifies a name (shorthand reference) that has been assigned to an autocall macro library.

Note that the SASAUTOS option uses filerefs, not librefs.
Details

Each autocall macro library consists of files in a UNIX directory. The directory-specification can be the pathname of a UNIX directory, a fileref, or an environment variable.

If you specify the pathname of a directory, you must enclose the name in quotation marks. You can omit the quotation marks only if you are specifying the name in the configuration file, in the SAS command, or in the SASV9_OPTIONS environment variable. And, you can omit the quotation marks only if the name cannot be interpreted as a fileref.

If you specify a fileref, you must define it before attempting to use any of the autocall macros. You can define the fileref in a FILENAME statement, in an environment variable, or with the FILENAME function. See “Assigning Filerefs to External Files or Devices with the FILENAME Statement” on page 85.

How you specify multiple directory names, filerefs, or environment variables depends on where you specify the SASAUTOS option:

- If you specify the SASAUTOS option in the configuration file or in the SASV9_OPTIONS environment variable, use either multiple SASAUTOS options, or enclose the directory names in parentheses. Separate the names with a comma or a blank space.

- If you specify the SASAUTOS option in the SAS command, use the APPEND or INSERT system options to append to the end or insert at the beginning of the current SASAUTOS value. For example, the following code adds /users/userid/also to the end of the current SASAUTOS value, /users/userid/here:

  sas -sasautos /users/userid/here -append sasautos /users/userid/also

  For more information, see “APPEND= System Option” in SAS System Options: Reference, and “INSERT= System Option” in SAS System Options: Reference.

- If you specify the SASAUTOS option in the OPTIONS statement or in the SAS System Options window, you must enclose the directory names in parentheses. Separate the names with a comma or a blank space.

At configuration time, SAS concatenates all directories specified for SASAUTOS. However, after the session starts, any new directories that you specify override any current autocall libraries.

The NOSASAUTOS option causes SAS to ignore all previous SASAUTOS specifications (whether specified in the SAS command, in the configuration file, or in the SASV9_OPTIONS environment variable).

The default value of the SASAUTOS option is the SASAUTOS fileref. There is no UNIX directory assigned to the fileref, so you must define the SASAUTOS fileref if you want to use it as your autocall library.

Examples:

Example 1: Specifying Multiple Environment Variables in the OPTIONS Statement

The following example shows the syntax to use if you are specifying multiple environment variables in the OPTIONS statement:

  options sasautos=(AUTODIR, SASAUTOS);
The environment variables that you specify must be defined. For example, you could define the AUTODIR environment variable at SAS command by using the following code:

    -set AUTODIR /tmp/sasautos

For more information about how to define an environment variable, see “SET System Option: UNIX” on page 442.

Example 2: Specifying a Fileref in the OPTIONS Statement
The fileref that you specify must be defined. For example, you could define the AUTODIR fileref using a FILENAME statement:

    filename AUTODIR '/tmp/sasautos';

Once the fileref is defined, you can use it in an OPTIONS statement to set the autocall library.

    options sasautos=autodir;

SASHELP System Option: UNIX
Specifies the locations of Sashelp libraries.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable
Category: Environment Control: Files
PROC OPTIONS GROUP=

Default: !SASROOT/sashelp (set in the installed !SASROOT/sasv9.cfg file)
UNIX specifics: directory-specification can also be an environment variable
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.
See: “SASHELP= System Option” in SAS System Options: Reference

Syntax

    -SASHELP directory-specification
--SASHELP ('directory-specification', 'directory-specification' ...)

Details

This option is set in the installation process and is not normally changed after installation. An environment variable can be specified as the value of SASHELP.

To add additional directory specifications, use the INSERT or APPEND system option. For more information, see "INSERT System Option: UNIX" on page 412, and "APPEND System Option: UNIX" on page 382.

See Also

System Options:
- "APPEND= System Option" in SAS System Options: Reference

---

SASSCRIPT System Option: UNIX

Specifies one or more storage locations of SAS/CONNECT script files.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Not included

Category: Communications: Networking and Encryption

PROC OPTIONS GROUP= COMMUNICATIONS

Default: !SASROOT/misc/connect

UNIX specifics: syntax for specifying multiple directory names

Note: This option can be restricted by a site administrator. For more information, see "Restricted Options" in SAS System Options: Reference.

Syntax

-SASSCRIPT 'directory-name' | ('directory-name-1', ..., 'directory-name-n')
SASSCRIPT='directory-name' | ('directory-name-1', ..., 'directory-name-n')

Details

How you specify multiple directory names in the same SASSCRIPT option depends on where you specify the SASSCRIPT option:
- If you specify the option in the configuration file or in the SASV9_OPTIONS environment variable, use either multiple SASSCRIPT options, or enclose the directory names in parentheses. Separate the names with a comma or a blank space.
If you specify the option in the SAS command, use multiple SASSCRIPT options because parentheses cause syntax errors.

If you specify the option in the OPTIONS statement or in the SAS System Options window, you must enclose the directory names in parentheses. Separate the names with a comma or a blank space.

See Also

System Options:
- “SASSCRIPT= System Option” in SAS/CONNECT User’s Guide

---

**SASUSER System Option: UNIX**

Specifies the name of the Sasuser library.

Category: Environment Control: Files

PROC OPTIONS GROUP= ENVFILES

Default: ~/sasuser.v94 (set in the installed !SASROOT/sasv9.cfg file)

UNIX specifics: `pathname` can be an environment variable

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “SASUSER= System Option” in SAS System Options: Reference

---

**Syntax**

```
-SASUSER pathname
```

**Details**

The `pathname` identifies the directory for the Sasuser library that contains a user's Profile catalog. You can use an environment variable to specify the pathname, for example:

```
sas -sasuser $HOME
```

---

**SET System Option: UNIX**

Defines an environment variable.
**PROC OPTIONS**

**GROUP= ENVFILES**

**Default:** None

**UNIX specifics:** syntax

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference*.

### Syntax

- SET variable-name value

  
  SET=variable-name='value'

### Details

The SET option lets you define an environment variable that is valid within the SAS session and any shell started from within the SAS session. Using the SET option is similar to using the SAS `setenv` command. For information about executing system commands from within your SAS session, see “Executing Operating System Commands from Your SAS Session” on page 17.

A special use for the SET option is to specify the name of the !SASROOT directory:

- set SASROOT pathname

The pathname specified can then be used to expand !SASROOT (as shown in Table 3.3 on page 62).

After exiting your SAS session, environment variables that are set with the SET option no longer exist.

### See Also

- “Defining Environment Variables in UNIX Environments” on page 285
- “Introduction to the !SASROOT Directory” on page 521

---

**SORTANOM System Option: UNIX**

Specifies options for the host sort utility.

**Valid in:** SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

**Category:** Sort: Procedure Options
PROC
OPTIONS
GROUP=

Default: None
UNIX specifics: all
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

SORTANOM=\textit{options}\
–SORTANOM \textit{options}

Required Argument

\textit{option}

can be any one or more of the following:

\textbf{B}

tells SyncSort to run in multi-call mode, instead of single-call mode. (See the documentation for \texttt{syncsort} for more information.)

\textbf{Note} This option is available for \texttt{syncsort} only.

\textbf{T}

writes to the SAS log statistics about the external sorting process.

\textbf{V}

writes to the SAS log all of the commands that are passed to the host sort utility.

\textbf{SORTCUT System Option: UNIX}

Specifies the data size in number of observations above which SAS uses the host sort instead of the internal SAS sort.

Category: Sort: Procedure Options

PROC
OPTIONS
GROUP=

Default: 0
UNIX specifics: all
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.
Syntax

-\textsc{sortcut} \textit{n} | \textit{nK} | \textit{nM} | \textit{nG} | \textit{hexX} | \textit{MIN} | \textit{MAX}

\textsc{sortcut}=\textit{n} | \textit{nK} | \textit{nM} | \textit{nG} | \textit{hexX} | \textit{MIN} | \textit{MAX}

Required Arguments

\textit{n} | \textit{nK} | \textit{nM} | \textit{nG}

specifies the number of observations in multiples of 1 (\textit{n}); 1,024 (\textit{nK}); 1,048,576 (\textit{nM}); or 1,073,741,824 (\textit{nG}). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 800 specifies 800 observations, a value of 0.782k specifies 801 observations, and a value of 3m specifies 3,145,728 observations.

\textbf{Note:} You can also specify the KB, MB, or GB syntax notations.

\textit{hexX}

specifies the number of observations as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the value 2ffx specifies 767 observations.

\textit{MIN}

specifies 0 observations.

\textit{MAX}

specifies 9,007,199,254,740,992 observations.

Details

When you specify \textsc{sortpgm}=\textsc{best}, SAS uses the value of the \textsc{sortcut} and \textsc{sortcupt} options to determine whether to use the host sort or the SAS sort. If the number of observations in the data set is greater than the number that you specify with \textsc{sortcut}, the host sort is used. If both \textsc{sortcut} and \textsc{sortcupt} are either not defined or are set to 0, the SAS sort is used. If you specify both options and either condition is true, SAS chooses the host sort.

See Also

\textbf{System Options:}

- "\textsc{sortcupt} System Option: UNIX" on page 445
- "\textsc{sortpgm} System Option: UNIX" on page 449

\textbf{SORTCUTP System Option: UNIX}

Specifies the data size in bytes above which SAS uses the host sort instead of the internal SAS sort.

\textbf{Valid in:}

SAS 9.4: Configuration file, SAS invocation, \textsc{options} statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, \textsc{options} statement, SASV9\_OPTIONS environment variable
Sort: Procedure Options

PROC OPTIONS
GROUP= SORT

Default: 0
UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-SORTCUTP n | nK | nM | nG | hexX | MIN | MAX
SORTCUTP=n | nK | nM | nG | hexX | MIN | MAX

Required Arguments

n | nK | nM | nG
specifies the number of bytes in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 bytes, a value of .782k specifies 801 bytes, and a value of 3m specifies 3,145,728 bytes.

Note: You can also specify the KB, MB, or GB syntax notations.

hexX
specifies the number of bytes as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the value 2dx specifies 45 bytes.

MIN
specifies 0 bytes.

MAX
specifies 9,007,199,254,740,992 bytes.

Details

When you specify SORTPGM=BEST, SAS uses the value of the SORTCUT and SORTCUTP options to determine whether to use the host sort or the SAS sort. If the data set to be sorted is larger than the number of bytes (or kilobytes or megabytes) that you specify with SORTCUTP, the host sort is used instead of the SAS sort. The value that you specify must be less than or equal to 2,147,483,647 bytes. If both SORTCUT and SORTCUTP are either not defined or are set to 0, the SAS sort is used. If you specify both options and either condition is true, SAS chooses the host sort.

The following equation computes the number of bytes to be sorted:

\[
\text{number-of-bytes} = ((\text{length-of-obs}) + (\text{length-of-all-keys})) \times \text{number-of-obs}
\]
SORTDEV System Option: UNIX

Specifies the pathname used for temporary files created by the host sort utility.

Category: Sort: Procedure Options

PROC OPTIONS GROUP=

Syntax

SORTDEV='directory-specification'

-SORTDEV directory-specification

Details

The SORTDEV option specifies an alternative directory for temporary files created by the host sort program.

SORTNAME System Option: UNIX

Specifies the name of the host sort utility.

Category: Sort: Procedure Options

PROC OPTIONS GROUP=

See Also

System Options:

- "SORTANOM System Option: UNIX" on page 443
- "SORTCUT System Option: UNIX" on page 444
- "SORTPGM System Option: UNIX" on page 449

Note:

This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.
Default: None
UNIX specifics: all
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

SORTNAME='host-sort-utility-name'
-SORTNAME host-sort-utility-name

Details

The SORTNAME option specifies the name of the default host sort utility, syncsort.

See Also

System Options:

- “SORTPGM System Option: UNIX” on page 449

SORTPARM System Option: UNIX

Specifies parameters for the host sort utility.

Category: Sort: Procedure Options

PROC OPTIONS GROUP=

Default: None
UNIX specifics: all
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

SORTPARM='parameter(s)'
-SORTPARM 'parameter(s)'

- ‘parameter(s)’
Required Argument

parameter

specifies any parameter that you want to pass to the sort utility. For a description of these parameters, see the documentation for the sort that you are using.

---

**SORTPGM System Option: UNIX**

Specifies whether to use the internal SAS sort utility or the host sort utility or to let SAS choose which sort utility to use.

**Valid in:**
- SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

**Category:** Sort: Procedure Options

**PROC OPTIONS GROUP=**

**Default:** BEST

**UNIX specifics:** all

**Note:** This option can be restricted by a site administrator. For more information, see “Restricted Options” in *SAS System Options: Reference*. 

---

**Syntax**

- `SORTPGM SAS | HOST | BEST`
- `SORTPGM=SAS | HOST | BEST`

**Required Arguments**

**SAS**

tells SAS to use the SAS sort.

**HOST**

tells SAS to use the sort that is specified by the SORTNAME system option.

**BEST**

tells SAS to use the best routine to sort the data set: the SAS sort or the host sort that is specified by the SORTNAME system option. When set, the settings of the SORTCUT and SORTCUTP system options determine whether SAS chooses the SAS sort or the host sort. When SORTCUT and SORTCUTP are not set (or when they are both 0), SAS selects the sorting algorithm based on the following order of precedence:

- host sort utility
- SAS sort utility
SORTSIZE System Option: UNIX

Specifies the amount of memory available to the SORT procedure.

Categories: Sort: Procedure Options
System Administration: Memory
System Administration: Performance

PROC OPTIONS GROUP=

Default: 1G

UNIX specifics: value of MAX

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “SORTSIZE= System Option” in SAS System Options: Reference

Syntax

SORTSIZE \n | \nK | \nM | \nG | \n | MIN | MAX

Required Arguments

\n | \nK | \nM | \nG

specifies the number of bytes in multiples of 1 (bytes); 1,024 (kilobytes); 1,048,576 (megabytes); or 1,073,741,824 (gigabytes). You can specify decimal values for the number of kilobytes, megabytes, or gigabytes. For example, a value of 8 specifies 8 bytes, a value of .782k specifies 801 bytes, and a value of 3m specifies 3,145,728 bytes.

Note: You can also specify the KB, MB, or GB syntax notations.
hexX specifies the amount of memory as a hexadecimal value. You must specify the value beginning with a number (0–9), followed by hexadecimal characters (0–9, A–F), and then followed by an X. For example, the value 2dx sets the amount of memory to 45 bytes.

MIN specifies 0 bytes, which indicates that there is no limit except the limitation specified by the MEMSIZE system option.

MAX specifies the maximum addressable memory for the operating environment.

Details
The SORT procedure uses the SORTSIZE system option to limit the amount of memory that it acquires or allocates for sorting. The amount of memory that SAS uses for the SORT procedure also depends on the values of the MEMSIZE and REALMEMSIZE system options. By contrast with the SORTSIZE option, the MEMSIZE system option places a limit on the total amount of virtual memory that SAS dynamically allocates at any time. This virtual memory is supported by a combination of real memory and paging space. The operating environment begins paging when the amount of virtual memory that is required exceeds the real memory that is available. To prevent paging and the associated performance problems, the SORTSIZE system option should be set to a subset of real memory. You can set SORTSIZE to MAX if MEMSIZE is set to a subset of real memory. In most cases, you can set SORTSIZE=MAX because this value limits the amount of memory that is used by the SORT procedure.

See Also

System Options:
- “MEMSIZE System Option: UNIX” on page 420

Procedures:
- Chapter 31, “SORT Procedure,” on page 507

STDIO System Option: UNIX
Specifies whether SAS should use stdin, stdout, and stderr.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: Input Control: Data Processing

PROC OPTIONS GROUP= INPUTCONTROL

Default: NOSTDIO

UNIX specifics: all
Syntax

–STDIO | –NOSTDIO

Details

This option tells SAS to take its input from standard input (stdin), to write its log to standard error (stderr), and to write its output to standard output (stdout).

This option is designed for running SAS in batch mode or from a shell script. If you specify this option interactively, SAS starts a line mode session. The STDIO option overrides the DMS, DMSEXP, and EXPLORER system options.

The STDIO option does not affect the assignment of the Stdio, Stdin, and Stderr filerefs. For more information, see “Filerefs Assigned by SAS in UNIX Environments” on page 91.

For example, in the following SAS command, the file myinput is used as the source program, and files myoutput and mylog are used for the procedure output and log respectively.

```sas
sas -stdio <myinput> myoutput> mylog
```

If you are using the C shell, you should use parentheses:

```c
(sas -stdio <myinput> myoutput)>& output_log
```

See Also

“The Default Routings for the SAS Log and Procedure Output in UNIX Environments” on page 105

STIMEFMT System Option: UNIX

Specifies the format that is used to display the time on FULLSTIMER and STIMER output.

Valid in:

- SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement, SASV9_OPTIONS environment variable

Category:

Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=

LOGCONTROL

Default:

512M

UNIX specifics:

all

Note:

This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.
Syntax

-STIMEFMT value
STIMEFMT=value

Required Argument

value specifies the options to use with STIMEFMT. The following options are available:

**Datetime Stamp options**

- **TS** specifies to always display the datetime stamp as part of STIMER and FULLSTIMER.
- **TSFULL** specifies to display the datetime stamp as part of FULLSTIMER. TSFULL is the default.
- **TSOFF** turns off the datetime stamp for STIMER and FULLSTIMER.

**Memory**

is normally displayed as part of FULLSTIMER. The default memory output is displayed in kilobytes. The following options for memory are available:

- **MEMFULL** writes memory statistics as part of FULLSTIMER, but not as part of STIMER.
- **MEM** writes memory statistics as part of FULLSTIMER and STIMER.
- **KB** writes memory in kilobytes.
- **MB** writes memory in megabytes.
- **GB** writes memory in gigabytes.
- **C** adds commas to the numbers in the memory display.
- **NC** does not add commas to the numbers in the memory display.

**Elapsed and CPU time**

can be configured to display hours, minutes, seconds, or best fit in STIMER and FULLSTIMER.

- **Z | H | HOURS** writes the time as hours:minutes:seconds.
- **M | MINUTES** writes the time as minutes:seconds.
- **S | SECONDS** writes the time as seconds.
- **HMS** writes the format leaving out leading zeros for hours and minutes.

**Counters**

specifies that additional counters can be displayed as part of FULLSTIMER.

- **E | ENABLE** enables extra counters.
- **D | DISABLE** disables extra counters.

**Help**

provides two values that are used to access help for the STIMEFMT option:

- **FMT** lists the available datetime stamp formats.
OPT     lists other option values that are available.

Details

STIMEFMT Basics

The STIMEFMT system enables you to customize the format of output produced by the STIMER and FULLSTIMER system options. You can perform the following tasks using STIMEFMT:

- list the formats that are available:
  
  ```
  options stimefmt=fmt;
  ```

- list other options that are available:
  
  ```
  options stimefmt=opt;
  ```

- turn the datetime stamp on or off for STIMER:
  
  ```
  options stimefmt=tson | tsoff | tsfull;
  ```

- combine options as needed:
  
  ```
  options stimefmt=(tson YNNDDS);
  ```

- separate a memory value with commas:
  
  ```
  options stimefmt=c;
  ```

- do not use commas when specifying values:
  
  ```
  options stimefmt=nc;
  ```

- select a unit for memory:
  
  ```
  options stimefmt=GB | MB | KB;
  ```

- turn on memory reporting for STIMER and FULLSTIMER:
  
  ```
  options stimefmt=mem;
  ```

- set the time display in the datetime stamp:
  
  ```
  options stimefmt=TOD | TIME | TIMEAMPM;
  ```
  (TOD and TIME specify military time.)

- control the display of CPU or real time by using hours or minutes

Formats for Displaying the Datetime Stamp

The format of the datetime stamp can be set to standard formats that are supported by SAS. These formats include the following:

- **ABS.** (Absolute seconds since Jan. 1, 1970)
- **DATE.** DATE9.
- **DDMMYY.**  DDMMYY10.  DDMMYYB.
- **DDMMYYB10.**  DDMMYYC.  DDMMYYC10.
- **DDMMYD.**  DDMMYYD10.  DDMMYYN.
- **DDMMYNN10.**  DDMMYYP.  DDMMYYP10.
- **DDMMYYS.**  DDMMYYS10.
ISO.          (ISO Standard Time)

MMDDYY.       MMDDYY10.       MMDDYY.
MMDDYYB10.    MMDDYYC.       MMDDYYC10.
MMDDYYD.      MMDDYYD10.     MMDDYYN.
MMDDYYN8.     MMDDYP.        MMDDYP10.
MMDDYYS.      MMDDYYS10.

NLDATM.       NLDATMAP.

YYMMDD.       YYMMDD10.       YYMMDD8.
YYMMDDB10.    YYMMDDC.       YYMMDDC10.
YYMMDDD.      YYMMDDD10.      YYMMDDN.
YYMMDDN8.     YYMMDDP.       YYMMDDP10.
YYMMDDS.      YYMMDDS10.

TOD.          (Writes time as military time.)
TIME.         (Writes time as military time.)
TIMEAMPM.     (Writes time as AM and PM.)

The syntax for the OPTIONS statement is listed below:

    options stimefmt=fmt;

where fmt is a valid SAS format.

Using Multiple Values for the STIMEFMT Option

The STIMEFMT option can specify multiple values at the same time to enable you
to set multiple settings. Multiple values must be enclosed in parentheses. For example:

    options stimefmt=(h YYMMDD. gb c);

Displaying the Settings for the STIMEFMT Option

PROC OPTIONS always displays the current state of all settings for STIMEFMT.
The following example shows log output when you execute PROC OPTIONS:

    proc options option=stimefmt;
    run;
Example Code 20.2  Log Output from PROC OPTIONS

```
SAS (r) Proprietary Software Release 9.4

STIMEFMT=(NLDATM2. HMS TIMEAMPM KB MEMFULL TSFULL NC)
    Specifies the format that is used to display the FULLSTIMER
    and STIMER output for timestamp, memory, CPU and elapsed time
    statistics.

NOTE: PROCEDURE OPTIONS used (Total process time):
    real time           0.00 seconds
    user cpu time       0.00 seconds
    system cpu time     0.00 seconds
    memory              21.37k
    OS Memory           11932.00k
    Timestamp            4/12/2013 01:51:52 PM
    Step Count                        14  Switch Count  0
    Page Faults                       0
    Page Reclaims                     1
    Page Swaps                        0
    Voluntary Context Switches        0
    Involuntary Context Switches      0
    Block Input Operations            0
    Block Output Operations           0
```

Resetting STIMEFMT to the Default Values

You can reset the settings for STIMEFMT to its default values by executing the
following OPTIONS statement:

```
options stimefmt=normal;
```

See Also

System Options:

- "FULLSTIMER System Option: UNIX" on page 403
- "STIMER System Option: UNIX" on page 456

STIMER System Option: UNIX

Specifies whether to write a subset of system performance statistics to the SAS log.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options
     window, SAS Viya: Configuration file, SAS invocation, OPTIONS statement,
     SASV9_OPTIONS environment variable

Category: Log and Procedure Output Control: SAS Log

PROC
OPTIONS
GROUP=

Default: STIMER

UNIX specifics: This option can be restricted by a site administrator. For more information, see
"Restricted Options” in SAS System Options: Reference.
Syntax

\texttt{–STIMER | –NOSTIMER}

\texttt{STIMER | NOSTIMER}

Required Arguments

\texttt{STIMER} \\
writes only real time and CPU time to the SAS log.

\texttt{NOSTIMER} \\
does not write any statistics to the SAS log.

Details

The STIMER system option specifies whether a subset of all the performance statistics of your system that are available to SAS are written to the SAS log. (Using STIMEFMT can affect the output.) Here is an example of STIMER output:

\textbf{Output 20.1} \textit{STIMER Output}

\begin{verbatim}
real time   1.34 seconds  
cpu time    0.04 seconds
\end{verbatim}

\textbf{Table 20.2} \textit{Description of STIMER Statistics}

\begin{tabular}{|l|l|}
\hline
Statistic & Description                                                          \\
\hline
real time  & the amount of time spent to process the SAS job. Real time is also     
           & referred to as elapsed time.                                        \\
CPU time   & the total time spent to execute your SAS code and to perform          
           & system overhead tasks on behalf of the SAS process. This value      
           & is the combination of the user CPU and system CPU statistics        
           & from FULLSTIMER.                                                   \\
\hline
\end{tabular}

If both \texttt{STIMER} and \texttt{FULLSTIMER} are set, the \texttt{FULLSTIMER} statistics are written to the SAS log.

Note: Starting in SAS 9, some procedures use multiple threads. On computers with multiple CPUs, the operating system can run more than one thread simultaneously. Consequently, CPU time might exceed real time in your STIMER output. For example, a SAS procedure could use two threads that run on two separate CPUs simultaneously. The value of CPU time would be calculated as the following:

\begin{verbatim}
CPU1 time + CPU2 time = total CPU time
1 second + 1 second = 2 seconds
\end{verbatim}

Because CPU1 can run a thread at the same time that CPU2 runs a separate thread, you can theoretically consume 2 CPU seconds in 1 second of real time.
SYSIN System Option: UNIX

Specifies the default location of SAS source code when running in batch mode.

Category: Environment Control: Files

PROC OPTIONS
GROUP=ENVFILES

Default: None

UNIX specifics: all

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-SYSIN filename | -NOSYSIN

Required Arguments

-SYSIN filename
    specifies an external file. The value for filename must be a valid UNIX filename.

-NOSYSIN
    invokes SAS, processes the autoexec file, and then terminates SAS, returning you to the command prompt.

Details

This option applies only when you are using batch mode. It is not necessary to precede the filename with the SYSIN option if the filename immediately follows the keyword SAS. For example, the following two SAS commands are equivalent:

    sas saspgms/report1.sas
    sas -sysin saspgms/report1.sas

The syntax of the SYSIN system option also enables you to specify NOSYSIN. If you specify NOSYSIN, SAS is invoked, the autoexec file is processed, and then SAS terminates, returning you to the command prompt. The following example shows the syntax:

    sas -nosysin -autoexec mysas.sas
This option is useful if you want to test an autoexec file without actually running a complete SAS session.

"Starting SAS Sessions in UNIX Environments" on page 4

SYSPRINT System Option: UNIX

Specifies the destination for printed output.

Valid in: SAS 9.4: Configuration file, SAS invocation, OPTIONS statement, SAS System Options window, SAS Viya: Not included

Category: Log and Procedure Output Control: Procedure Output

PROC OPTIONS GROUP=

Default: Default system printer

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

–SYSPRINT destination | 'destination-option-list'

SYSPRINT=destination | 'destination-option-list'

Required Arguments

destination

is the name of a hard-copy device at your site. Consult your system administrator for a list of available destinations.

destination-option-list

is the list of options to pass to the lp (or lpr) command.

Details

The SYSPRINT option specifies a destination for printed output other than the default system printer. You can use the option list to pass options to the lp (or lpr) command.

Note: When a fileref is assigned, the SYSPRINT option is queried. If the value of the SYSPRINT option is later changed, the fileref does not pick up this change.

For more information, see “Changing the Default Print Command in UNIX Environments” on page 118.
See Also

Commands:
- “PRINTCMD System Option: UNIX” on page 432

Other References:
- “Overview of Printing Output in UNIX Environments” on page 104

USER System Option: UNIX

Specifies the name of the default permanent SAS library.

Category: Environment Control: Files

PROC OPTIONS GROUP=

Default: None

UNIX specifics: *pathname* must be a valid UNIX pathname

Note: This option cannot be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “USER= System Option” in SAS System Options: Reference

Syntax

-USER *pathname*

USER='*pathname*’ | *libref*

Required Arguments

*pathname*

identifies the directory containing your default permanent SAS library. It must be a directory name.

*libref*

is the libref associated with the directory containing your default permanent SAS library. It must already be assigned.

See Also

“Using One-Level Names to Access Permanent Files (User Library)” on page 70
VERBOSE System Option: UNIX

Specifies whether SAS writes the system option settings to the SAS log.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: Log and Procedure Output Control: SAS Log

PROC OPTIONS GROUP=

Default: NOVERBOSE

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-VERBOSE | NOVERBOSE

Required Arguments

-VERBOSE

writes the settings of SAS system options from the configuration file, the SAS command, and the SASV9_OPTIONS environment variable to the SAS log. For the CONFIG option, VERBOSE lists the names of the configuration files.

-NOVERBOSE

does not write the settings of the system options to the SAS log.

Details

In previous releases of SAS, the output from the VERBOSE system option appeared as a simple list of options and their values. The list appeared in the window where SAS was invoked. Pressing the Enter key advanced the list one line at a time. Pressing the spacebar advanced the list page by page. Pressing the Q key displayed the entire list, and brought you back to the prompt.

For SAS 9.4 and beyond, the list of system options and their values is still created. In addition, SAS creates a list that identifies where the options were set. This list is written to a global journal file, and then it is written to the SAS log. The advantage of writing to a global journal file is that if SAS fails to initialize, output is still available, even though a SAS log was not created.

See Also

System Options:

- “OPLIST System Option: UNIX” on page 428
**WORK System Option: UNIX**

Specifies the location of the Work library.

Category: Environment Control: Files

**PROC OPTIONS GROUP= ENVFILES**

Default: Set in the installed !SASROOT/sasv9.cfg file

UNIX specifics: all

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “WORK= System Option” in SAS System Options: Reference

**Syntax**

\[ \text{–WORK } \text{filename | directory} \]

**Required Arguments**

*filename*

specifies a file that contains a list of directories and optional keywords. SAS chooses a directory from the list in the file as the location for the Work library for the current SAS session.

*directory*

specifies a directory as the location for the Work library for the current SAS session.

**Details**

**The Basics**

If you use the *filename* option, SAS opens the file, and selects one of the directories to use as the location for the Work library. SAS either randomly selects a directory or selects a directory based on available space. You use the METHOD keyword to make your selection.

If you use the *directory* option, SAS continues its initialization using the specified directory as the location for the Work library.

**Making the Allocation of Work Libraries More Dynamic**

The *filename* option contains a list of directories that can be used for the Work library. Individual SAS Work libraries still reside in a single directory. You use
METHOD=RANDOM to specify that the directory for the Work library is randomly chosen from the list of directories. SAS selects one directory per session as the location for the Work library. This selection enables you to balance the I/O load across multiple hardware systems. You use METHOD=SPACE to specify the directory that has the most available space. If the METHOD keyword is not specified, SAS defaults to randomly selecting a directory.

Examples:

Example 1: Spreading a Processing Load across Multiple Volumes of Different Disks

The following example shows how to spread an I/O processing load across multiple volumes of different disks. In this case, you use METHOD=RANDOM. A file named /sasinfo/workfiles contains the following information:

```
/disk1/sastempfiles
/disk2/sastempfiles
/disk3/sastempfiles
method=random
```

The Work library for a particular SAS session is placed on either disk1, disk2, or disk3. The configuration file or command line would include the following:

```
-work /sasinfo/workfiles
```

Example 2: Choosing the Directory That Has the Most Available Space

When you process your data, you can select the directory that has the most available space. In this case, you use METHOD=SPACE. In the following example, /sasinfo/workfiles contains the following directories:

```
/disk1/sastempfiles
/disk2/sastempfiles
/disk3/sastempfiles
method=space
```

The Work library is placed on the disk with the most available space.

See Also

System Options:

- “WORKINIT System Option: UNIX” on page 463

WORKINIT System Option: UNIX

Initializes the Work library.

Category: Environment Control: Files
PROC OPTIONS
GROUP=

Default: WORKINIT

UNIX specifics: WORKINIT does not erase files from previous sessions

Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

See: “WORKINIT System Option” in SAS System Options: Reference

Syntax

–WORKINIT | –NOWORKINIT

Required Arguments

-WORKINIT
specifies that a new subdirectory is to be created in the directory specified in the WORK option.

-NOWORKINIT
specifies that the system is to use the directory specified by the WORK option.

- If the system does not find any old subdirectories, it creates a new one.
- If the system finds more than one old subdirectory, it uses the latest one.
- If file locking is in effect (see “FILELOCKS System Option: UNIX” on page 397), the system looks for the latest unlocked directory. If it finds none, then it creates a new one.

Details

The WORKINIT option controls whether the Work library is initialized at SAS command.

See Also

System Options:

- “FILELOCKS System Option: UNIX” on page 397
- “WORK System Option: UNIX” on page 462

WORKPERM System Option: UNIX

Sets the permissions of the SAS Work library when it is initially created.

Valid in: SAS 9.4: Configuration file, SAS invocation, SAS Viya: Configuration file, SAS invocation, SASV9_OPTIONS environment variable

Category: Environment Control: Files
PROC OPTIONS GROUP= ENVFILES

Default: 700
UNIX specifics: all
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

–WORKPERMS permission-value

Required Argument

permission-value specifies the octal value representing the permissions for the SAS Work directory. Values can be any octal value setting the permission of a UNIX directory. Examples of values include umask, 700, 755, 770, 775, and 777.

Details

The WORKPERMS system option enables you to change or remove the current file mode creation mask value when you initially create a SAS Work library. This means that you can change the value of permission-value to change file permissions for a new Work library.

XCMD System Option: UNIX

Specifies whether the X command is valid in the SAS session.

Category: Environment Control: Display

PROC OPTIONS GROUP= ENVDISPLAY

Default: XCMD
UNIX specifics: all
Note: This option can be restricted by a site administrator. For more information, see “Restricted Options” in SAS System Options: Reference.

Syntax

-XCMD | -NOXCMD
Required Arguments

-XCMD
  specifies that the X command is valid in the current SAS session.

-NOXCMD
  specifies that the X command is not valid in the current SAS session.

Details

The XCMD system option specifies whether the X command is valid in the current SAS session.

You cannot use several SAS statements, objects, or facilities if you use the NOXCMD system option. Examples of these statements, objects, and facilities include the following:

- the PIPE device type in the FILENAME statement
- the CALL SYSTEM routine
- the %SYSEXEC macro
- any facility that SAS uses to execute a shell-level command

Overview

SAS Procedures under UNIX

This section describes SAS procedures that have behavior or syntax that is specific to UNIX environments. Each procedure description includes a brief “UNIX specifics” section that explains which aspect of the procedure is specific to UNIX. Each procedure is described in both this documentation and in the Base SAS Procedures Guide.

If the information under the "UNIX specifics" is "all," then the procedure is described only in this documentation.
Overview: CATALOG Procedure: UNIX

UNIX-Specific Behavior for the CATALOG Procedure

Note: This documentation is a simplified version of the CATALOG procedure documentation. For the complete syntax and its explanation, see “CATALOG Procedure” in Base SAS Procedures Guide.

The FILE= option in the CONTENTS statement of the CATALOG procedure accepts a fileref. If the name specified does not correspond to a fileref, a file with that name and an extension of .lst is created in the current directory. For example, if myfile is not a fileref, the following code creates the file myfile.lst in your current directory:

```sas
proc catalog catalog=sasuser.profile;
    contents file=myfile;
run;
```

SAS writes the following output to the Log:

```
NOTE: 6 entries have been written to the output file /users/userid/MYFILE.lst.
```

Note: The filename that is created is always stored in lowercase, even if you specified it in uppercase. In the SAS log, however, the filename is listed in uppercase.
Syntax: CATALOG Procedure: UNIX

Restriction: This procedure is not included in SAS Viya.

UNIX specifics: FILE= option in the CONTENTS statement

See: “CATALOG Procedure” in Base SAS Procedures Guide

**PROC CATALOG** CATALOG=<libref.> catalog <ENTRYTYPE=etype> <KILL>;
    CONTENTS <OUT=SAS-data-set> <FILE=fileref>;

<table>
<thead>
<tr>
<th>Statement</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTENTS</td>
<td>Print the contents of a catalog</td>
</tr>
</tbody>
</table>

**CONTENTS Statement: UNIX**

Prints the contents of a SAS catalog.

Syntax

    CONTENTS <OUT=SAS-data-set> <FILE=fileref>;

Optional Argument

*fileref*

names a file specification that is specific to the UNIX operating environment.
Overview: CIMPORT Procedure: UNIX

UNIX-Specific Behavior for the CIMPORT Procedure

Note: This documentation is a simplified version of the CIMPORT procedure documentation. For the complete syntax and its explanation, see "CIMPORT Procedure" in Base SAS Procedures Guide.

Starting in SAS 9.1, you can use the MIGRATE procedure to migrate a SAS library from a previous release. For more information, see "Migrating 32-Bit SAS Files to 64-Bit in UNIX Environments" on page 54, the MIGRATE procedure, and Cross-Release Compatibility at the SAS Technical Support site.

The CIMPORT procedure imports a transport file that was created (exported) by the CPORT procedure. The transport file can contain a SAS data set, a SAS catalog, or an entire SAS library.

Typically, the INFILE= option is used to designate the source of the transport file. If this option is omitted, CIMPORT uses the default file Sascat.dat in the current directory as the transport file.

Note: CIMPORT works only with transport files created by the CPORT procedure. If the transport file was created using the XPORT engine with the COPY procedure, then another PROC COPY must be used to restore the transport file. For more information, see "COPY Procedure" in Base SAS Procedures Guide.
Syntax: CIMPORT Procedure: UNIX

Restriction: This procedure is not included in SAS Viya.
UNIX specifics: name and location of transport file
See: “CIMPORT Procedure” in Base SAS Procedures Guide

**PROC CIMPORT** destination=libref | <libref.>member-name <options>;

<table>
<thead>
<tr>
<th>Statement</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROC CIMPORT</td>
<td>Restore a transport file</td>
</tr>
</tbody>
</table>

PROC CIMPORT Statement: UNIX

Restores a transport file that was created by the CPOR procedure.

Syntax

**PROC CIMPORT** destination=libref | <libref.>member-name <options>;

Required Arguments

*destination*
identifies the files in the transport file as a single SAS data set, single SAS catalog, or multiple members of a SAS library.

*libref | <libref.>member-name*
specifies the name of the SAS data set, catalog, or library to be created from the transport file.

See Also

Procedures:
- Chapter 26, “CPOR Procedure,” on page 487

Other References:
- “Migrating 32-Bit SAS Files to 64-Bit in UNIX Environments” on page 54
- “Moving and Accessing SAS Files between Operating Environments” in Moving and Accessing SAS Files
Example 1: Moving Data Sets CIMPORT
Procedure: UNIX

Example 1: Moving Data Sets

For this example, a SAS library that contains multiple SAS data sets was exported to a file (called transport-file) using the CPORT procedure on a foreign host. The transport file is then moved by a binary transfer to the receiving host.

The following code extracts all of the SAS data sets and catalogs stored within the transport file and restores them to their original state in the new library, called SAS-library.

```sas
libname newlib 'SAS-library';
filename tranfile 'transport-file';
proc cimport lib=newlib infile=tranfile;
run;
```
Overview: CONTENTS Procedure: UNIX

UNIX-Specific Behavior for the CONTENTS Procedure

Note: This documentation is a simplified version of the CONTENTS procedure documentation. For the complete syntax and its explanation, see "CONTENTS Procedure" in Base SAS Procedures Guide.

In SAS 9.4M3, the CONTENTS procedure displays file size in KB, MB, or GB, as appropriate. This value is an approximation and is sufficient for most purposes. The CONTENTS procedure also displays the exact file size in bytes.

The CONTENTS procedure produces the same information as the CONTENTS statement in the DATASETS procedure. (See Chapter 27, "DATASETS Procedure," on page 491 for a comparison.)

Syntax: CONTENTS Procedure: UNIX

Category: CAS

UNIX specifics: information displayed in the SAS output

See: "CONTENTS Procedure" in Base SAS Procedures Guide

PROC CONTENTS <options>;}
PROC CONTENTS Statement: UNIX
Prints the description of the contents of one or more files from a SAS library.

Syntax
PROC CONTENTS <options>;

Example: Executing PROC CONTENTS

Example 1: Executing PROC CONTENTS
The following SAS code executes PROC CONTENTS to describe the Sashelp.Zipcode data set:

```sas
proc contents data=sashelp.zipcode;
run;
```
### Example 1: Executing PROC CONTENTS

#### Output from PROC CONTENTS

**The SAS System**

**Sorted Information**
- Sorted By: ZIP, ZIP_CLASS
- Validated: YES
- Character Set: ANSI
Overview: CONVERT Procedure: UNIX

What Does the CONVERT Procedure Do?

The CONVERT procedure converts BMDP and OSIRIS system files, and SPSS export files to SAS data sets. The procedure is supplied for compatibility. The procedure invokes the appropriate engine to convert files.

PROC CONVERT produces one output data set, but no printed output. The new data set contains the same information as the input system file. Exceptions are noted in "How Missing Values Are Handled" on page 482.

The procedure converts system files from these products:

- BMDP saves files up to and including the most recent release of BMDP (available for AIX, HP-UX, and Solaris only).
- OSIRIS saves files through and including OSIRIS IV. (Hierarchical file structures are not supported.)

Because the BMDP, OSIRIS, and SPSS products are maintained by other organizations, changes to these products might make new files incompatible with the current version of PROC CONVERT. SAS upgrades PROC CONVERT to support changes to these products only when a new version of SAS is released.
How Missing Values Are Handled

If a numeric value in the output data set has no value or has a system missing value, PROC CONVERT assigns it a missing value.

How Variable Names Are Assigned

Overview of Variable Name Assignments

The following sections explain how names are assigned to the SAS variables created by the CONVERT procedure.

CAUTION
Make sure that the translated names are unique. Variable names are translated as indicated in the following sections.

Variable Names in BMDP Output

Variable names from the BMDP save file are used in the SAS data set, but nontrailing blanks and all special characters are converted to underscores in the SAS variable names. The subscript in BMDP variable names, such as x(1), becomes part of the SAS variable name with the parentheses omitted: X1. Alphabetic BMDP variables become SAS character variables of corresponding length. Category records from BMDP are not accepted.

Variable Names in OSIRIS Output

For single-response variables, the V1 through V9999 name becomes the SAS variable name. For multiple-response variables, the suffix Rn is added to the variable name where \( n \) is the response. For example, V25R1 would be the first response of the multiple-response V25. If the variable after V1000 has 100 or more responses, responses above 99 are eliminated. Numeric variables that OSIRIS stores in character, fixed-point binary, or floating-point binary mode become SAS numeric variables. Alphabetic variables become SAS character variables; any alphabetic variable of length greater than 200 is truncated to 200. The OSIRIS variable description becomes a SAS variable label, and OSIRIS print format information becomes a SAS format.
Variable Names in SPSS Output

SPSS variable names and variable labels become variable names and labels without change. SPSS alphabetic variables become SAS character variables of the same length. SPSS blank values are converted to SAS missing values. SPSS print formats become SAS formats, and the SPSS default precision of no decimal places becomes part of the variables' formats. The SPSS DOCUMENT data is copied so that the CONTENTS procedure can display it. SPSS value labels are not copied.

Comparison with Interface Library Engines

The CONVERT procedure is closely related to the interface library engines BMDP, OSIRIS, and SPSS. (In fact, the CONVERT procedure uses these engines.) For example, the following two sections of code provide identical results:

```plaintext
filename myfile 'mybmdp.dat';
proc convert bmdp=myfile out=temp;
run;
libname myfile bmdp 'mybmdp.dat';
data temp;
set myfile._first_
run;
```

However, the BMDP, OSIRIS, and SPSS engines provide more extensive capability than PROC CONVERT. For example, PROC CONVERT converts only the first BMDP member in a save file. The BMDP engine, in conjunction with the COPY procedure, copies all members.

Syntax: CONVERT Procedure: UNIX

Restriction: This procedure is not included in SAS Viya.
UNIX specifics: all

```
PROC CONVERT product-specification <option-list>;
```

<table>
<thead>
<tr>
<th>Statement</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROC CONVERT</td>
<td>Convert BMDP and OSIRIS system files and SPSS export files</td>
</tr>
</tbody>
</table>

PROC CONVERT Statement: UNIX

Converts BMDP and OSIRIS system files and SPSS export files to SAS data sets.
Syntax

PROC CONVERT product-specification <option-list>;

Required Argument

product-specification

Product-specification can be one of the following:

BMDP=fileref <(CODE=code CONTENT=content-type)> 
converts the first member of a BMDP save file created under UNIX (AIX) into a SAS data set. Here is an example:

filename save '/usr/mydir/bmdp.dat';
proc convert bmdp=save;
run;

If you have more than one save file in the BMDP file referenced by the fileref argument, you can use two options in parentheses after fileref. The CODE= option specifies the code of the save file that you want, and the CONTENT= option specifies the content of the save file. For example, if a file with code=judges has a content of DATA, you can use the following statements:

filename save '/usr/mydir/bmdp.dat';
proc convert bmdp=save(code=judges
       content=data);
run;

OSIRIS=fileref | libref 
specifies a fileref or libref for the OSIRIS file to be converted into a SAS data set. You must also include the DICT= option.

SPSS=fileref | libref 
specifies a fileref or libref for the SPSS export file that is to be converted into a SAS data set. The SPSS file must be created by using the SPSS EXPORT command, but it can be from any operating environment.

Optional Argument

option-list

Option-list can be one of the following:

DICT=fileref | libref 
specifies a fileref or libref of the dictionary file for the OSIRIS file. DICT= is valid only when used with the OSIRIS product specification.

FIRSTOBS=n 
gives the number of the observation where the conversion is to begin, so that you can skip observations at the beginning of the BMDP, OSIRIS, or SPSS file.

OBS=n 
specifies the number of the last observation to be converted. This option enables you to exclude observations at the end of the file.

OUT=SAS-data-set 
names the SAS data set that holds the converted data. If OUT= is omitted, SAS still creates a Work data set and automatically names it DATA$n, just as if you had omitted a data set name in a DATA statement. For more information, see For more information, see "Introduction to SAS Files, Libraries, and Engines in UNIX Environments" on page 43.
Examples: CONVERT Procedure: UNIX

Example 1: Converting a BMDP Save File
The following statements convert a BMDP save file and produce the temporary SAS data set _temp_, which contains the converted data:

```sas
filename bmdpfile 'bmdp.savefile';
proc convert bmdp=bmdpfile out=temp;
run;
```

Example 2: Converting an OSIRIS File
The following statements convert an OSIRIS file and produce the temporary SAS data set _temp_, which contains the converted data:

```sas
filename osirfile 'osirdata';
filename dictfile 'osirdict';
proc convert osiris=osirfile dict=dictfile out=temp;
run;
```

Example 3: Converting an SPSS File
The following statements convert an SPSS file and produce the temporary SAS data set _temp_, which contains the converted data:

```sas
filename spssfile 'spssfile.num1';
proc convert spss=spssfile out=temp;
run;
```
Overview: CPORT Procedure: UNIX

UNIX-Specific Behavior for the CPORT Procedure

Note: This version is a simplified version of the CPORT procedure syntax. For the complete syntax and its explanation, see “CPORT Procedure” in Base SAS Procedures Guide.

Starting in SAS 9.1, you can use the MIGRATE procedure to migrate a SAS library from a previous release. For more information, see "Migrating 32-Bit SAS Files to 64-Bit in UNIX Environments" on page 54, and the SAS Technical Support site.

The CPORT procedure creates a transport file to later be restored (imported) by the CIMPORT procedure. The transport file can contain a SAS data set, SAS catalog, or an entire SAS library.

Typically, the FILE= option is used to specify the path of the transport file. The value of the FILE= option can be a fileref defined in a FILENAME statement or an environment variable. If this option is omitted, CPORT creates the default file Sascat.dat in the current directory as the transport file.

Note: The specification of the transport file is specific to UNIX directories.
Syntax: CPORT Procedure: UNIX

Restriction: This procedure is not included in SAS Viya.
UNIX specifics: name and location of transport file
See: “CPORT Procedure” in Base SAS Procedures Guide

```sas
PROC CPORT source-type=libref | <libref.>member-name <options>;
```

<table>
<thead>
<tr>
<th>Statement</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROC CPORT</td>
<td>Write SAS data sets and catalogs into a transport file</td>
</tr>
</tbody>
</table>

PROC CPORT Statement: UNIX

Writes SAS data sets and catalogs into a transport file.

Syntax

```
PROC CPORT source-type=libref | <libref.>member-name <options>;
```

Required Arguments

```sas
source-type
```
identifies the files to export as either a single SAS data set, single SAS catalog, or multiple members of a SAS library.

```sas
libref | <libref.> member-name
```
specifies the name of the SAS data set, catalog, or library to be exported.

Procedures:

- Chapter 23, “CIMPORT Procedure,” on page 473

Other References:

- “Migrating 32-Bit SAS Files to 64-Bit in UNIX Environments” on page 54
- “Moving and Accessing SAS Files between Operating Environments” in Moving and Accessing SAS Files
Example 1: Exporting Files

In this example, a SAS library called `oldlib` contains multiple SAS data sets and is being exported to the file called `transport-file`:

```sas
libname oldlib 'SAS-data-library';
filename tranfile 'transport-file';

proc cport lib=oldlib file=tranfile;
run;
```

This transport file is then typically moved by binary transfer to a different host, where the CIMPORT procedure is used to restore the SAS library.
Overview: DATASETS Procedure: UNIX

UNIX-Specific Behavior for the DATASETS Procedure

Note: This documentation is a simplified version of the DATASETS procedure documentation. For the complete syntax and its explanation, see “DATASETS Procedure” in Base SAS Procedures Guide.

The output from the DATASETS procedure shows you the libref, engine, and physical name that are associated with the library. The output provides the names and other properties of the SAS files that are contained in the library. Some of the SAS library information, such as the filenames and access permissions, that is displayed in the SAS log by the DATASETS procedure depends on the operating environment and the engine. The information generated by the CONTENTS statement also varies according to the device type or access method associated with the data set.

If you specify the DIRECTORY option in the CONTENTS statement, the directory information is displayed in both the Log and Output windows.

The CONTENTS statement in the DATASETS procedure generates the same engine and host-dependent information as the CONTENTS procedure.
Syntax: DATASETS Procedure: UNIX

Category: CAS
UNIX specifics: Directory information, CONTENTS statement output
See: “DATASETS Procedure” in Base SAS Procedures Guide

PROC DATASETS <options>;
  CONTENTS <option>;

<table>
<thead>
<tr>
<th>Statement</th>
<th>Task</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTENTS</td>
<td>Describe the contents of one or more SAS data sets and print the directory of the SAS library</td>
<td>Ex. 2</td>
</tr>
</tbody>
</table>

CONTENTS Statement

Describes the contents of one or more SAS data sets and prints the directory of the SAS library.

Syntax

CONTENTS <UNIX-specific-option>;

Optional Argument

UNIX-specific-option

specifies a UNIX-specific option for the CONTENTS statement. Here is the possible value:

DIRECTORY

writes a list of information specific to the UNIX operating environment.

For a complete list of options for this statement, see "CONTENTS Statement" in Base SAS Procedures Guide.

See Also

Procedures:
- “CONTENTS Procedure” in Base SAS Procedures Guide
Example 1: Sample Data

The next example uses these text files as input for the IMPORT procedure and then generates output for the DATASETS procedure.

Here are the contents of the space-delimited file grades.txt:

<table>
<thead>
<tr>
<th>Student</th>
<th>Year</th>
<th>State</th>
<th>Grade1</th>
<th>Grade2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
<td>1980</td>
<td>NC</td>
<td>85</td>
<td>87</td>
</tr>
<tr>
<td>1042</td>
<td>1981</td>
<td>MD</td>
<td>92</td>
<td>92</td>
</tr>
<tr>
<td>1095</td>
<td>1979</td>
<td>PA</td>
<td>100</td>
<td>72</td>
</tr>
<tr>
<td>1187</td>
<td>1980</td>
<td>MA</td>
<td>87</td>
<td>94</td>
</tr>
</tbody>
</table>

Here are the contents of the space-delimited file majors.txt:

<table>
<thead>
<tr>
<th>Student</th>
<th>Year</th>
<th>State</th>
<th>Grade1</th>
<th>Grade2</th>
<th>Major</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
<td>1980</td>
<td>NC</td>
<td>84</td>
<td>87</td>
<td>Math</td>
</tr>
<tr>
<td>1042</td>
<td>1981</td>
<td>MD</td>
<td>92</td>
<td>92</td>
<td>History</td>
</tr>
<tr>

<td>Dance</td>
</tr>
<tr>
<td>1204</td>
<td>1981</td>
<td>NC</td>
<td>82</td>
<td>96</td>
<td>French</td>
</tr>
</tbody>
</table>

Example 2: Describing SAS Data Sets

The following SAS code creates two SAS data sets, classes.grades and classes.majors, and executes PROC DATASETS using classes.majors as the input data set.

The first page of output from this example is produced by the DIRECTORY option in the CONTENTS statement. This information also appears in the SAS log. Page 2 in this output describes the data set classes.majors and appears only in the SAS output:

```sas
libname classes '.';

proc import datafile='./mydata/grades.txt'
    dbms=dlm
    out=classes.grades
    replace;
    delimiter=' '; run;

proc import datafile='./mydata/majors.txt'
    dbms=dlm
    out=classes.majors
    replace;
    delimiter=' ';```

Example 2: Describing SAS Data Sets
run;

proc datasets library=classes;
  contents data=majors directory;
run;

Output 27.1  Output from the DATASETS Procedure

Overview: OPTIONS Procedure: UNIX

UNIX-Specific Behavior for the OPTIONS Procedure

Note: This documentation is a simplified version of the OPTIONS procedure syntax. For the complete syntax and its explanation, see ”OPTIONS Procedure” in SAS System Options: Reference.

PROC OPTIONS lists the current settings of the system options that are available in all operating environments, as well as the system options that are available in the UNIX environment. If you specify the HOST option in the PROC OPTIONS statement, it lists those options that are available only under UNIX (host options). The option values that are displayed by PROC OPTIONS depend on the default values of SAS, the default values specified by your site administrator, the default values in your own configuration file, any changes made in your current session through the OPTIONS statement, and possibly, the device on which you are running SAS.

For information about a specific option, see ”SAS System Options under UNIX” on page 376.

Syntax: OPTIONS Procedure: UNIX

Category: CAS
UNIX specifics: options that are available only under UNIX

See: “OPTIONS Procedure” in SAS System Options: Reference

PROC OPTIONS <options>;

PROC OPTIONS Statement: UNIX
Lists the current settings of SAS system options.

Syntax
PROC OPTIONS <option>;

Optional Argument
option
requests details about a set of options.
HOST
displays only host-specific options.
NOHOST
displays only portable (host-independent) options.

Alias PORTABLE

See Also
“Order of Precedence for Processing SAS Configuration Files” on page 27

Usage: OPTIONS Procedure: UNIX

Identify Where an Option Was Set

You can specify the VALUE option in a PROC OPTIONS statement to identify the option’s scope and the method that was used to set the option. If an option’s value is set using multiple methods (for example, in an OPTIONS statement or in multiple configuration files), the VALUE option identifies which method determines the effective value. If the method is a configuration file, the VALUE option identifies the file path.

Use the following PROC OPTIONS statement to specify the VALUE option:

    proc options option=option-name value;
For more information, see "OPTIONS Procedure" in SAS System Options: Reference.
Overview: PMENU Procedure: UNIX

UNIX-Specific Behavior for the PMENU Procedure

Note: This version is a simplified version of the PMENU procedure syntax. For the complete syntax and its explanation, see “PMENU Procedure” in Base SAS Procedures Guide.

The PMENU procedure defines PMENU facilities for dialog boxes that are created by using the WINDOW statement in Base SAS software, the %WINDOW macro statement, the BUILD procedure of SAS/AF software, or the SAS Component Language (SCL) PMENU function with SAS/AF and SAS/FSP software.

Under UNIX, the following options are ignored:

- ATTR= and COLOR= options in the TEXT statement. The colors and attributes for text and input fields are controlled by the CPARMS colors specified in the SASCOLOR window. For more information, see “Customizing Colors in UNIX Environments” on page 221.
- ACCELERATE= and the MNEMONIC= options in the “TITLE Statement” in SAS Global Statements: Reference.

Syntax: PMENU Procedure: UNIX

Restriction: This procedure is not included in SAS Viya.
UNIX specifics: ATTR= and COLOR= options in the TEXT statement have no effect; ACCELERATE= and MNEMONIC= options in the ITEM statement are ignored

See: “PMENU Procedure” in Base SAS Procedures Guide

PROC PMENU <CATALOG=<libref.>catalog> <DESC 'entry-description'>;
PRINTTO Procedure: UNIX

Overview: PRINTTO Procedure: UNIX

UNIX-Specific Behavior for the PRINTTO Procedure

Note: This version is a simplified version of the PRINTTO procedure syntax. For the complete syntax and its explanation, see “PRINTTO Procedure” in Base SAS Procedures Guide.

Use the PRINTTO procedure to direct program output or log output to a file that is different from the default locations. In a UNIX environment, the file specifications for the LOG= or PRINT= options in the PROC PRINTTO statement must be compatible with UNIX locations.

Syntax: PRINTTO Procedure: UNIX

PROC PRINTTO <option>;

Valid values of file-specification

“PRINTTO Procedure” in Base SAS Procedures Guide
PROC PRINTTO Statement: UNIX

Defines destinations for SAS procedure output and the SAS log.

Syntax

PROC PRINTTO <option>;

Optional Argument

option

specifies an option to use with the PRINTTO procedure. The following options are available:

LOG=file-specification

specifies a fully qualified pathname (in quotation marks), an environment variable, a fileref, or a file in the current directory (without extension).

PRINT=file-specification

specifies a fully qualified pathname (in quotation marks), an environment variable, a fileref, or a file in the current directory (without extension). If you specify a fileref that is defined with the PRINTER device-type keyword, output is sent directly to the printer.

See Also

"Overview of Printing Output in UNIX Environments" on page 104

Usage: PRINTTO Procedure: UNIX

Send Program Output to an Alternate Location

The following statements send any SAS log entries that are generated after the RUN statement to the external file that is associated with the fileref myfile:

```
filename myfile '/users/myid/mydir/mylog';
proc printto log=myfile;
run;
```
If `myfile` has not been defined as a fileref, then PROC PRINTTO creates the file `myfile.log` in the current directory.

The following statements send any procedure output that is generated after the RUN statement to the file `/users/myid/mydir/myout`:

```sas
proc printto print="/users/myid/mydir/myout";
run;
```

The following statements send the procedure output from the CONTENTS procedure directly to the system printer:

```sas
filename myfile printer;
proc printto print=myfile;
run;
proc contents data=oranges;
run;
```

To redirect the SAS log and procedure output to their original default destinations, run PROC PRINTTO without any options:

```sas
proc printto;
run;
```

If filerefs `myprint` and `mylog` have not been defined, then the following statements send any SAS procedure output to `myprint.lst` and any log output to `mylog.log` in the current directory:

```sas
proc printto print=myprint log=mylog;
run;
```

If filerefs `myprint` and `mylog` had been defined, the output would have gone to the files that are associated with those filerefs.
Overview: SORT Procedure: UNIX

UNIX-Specific Behavior for the SORT Procedure

Note: This version is a simplified version of the SORT procedure syntax. For the complete syntax and its explanation, see “SORT Procedure” in Base SAS Procedures Guide.

The SORT procedure sorts observations in a SAS data set by one or more character or numeric variables. The procedure then either replaces the original data set or creates a new, sorted data set. By default under UNIX, the SORT procedure uses the ASCII collating sequence.

The SORT procedure uses the sort utility that is specified by the SORTPGM system option. Sorting can be done by SAS or by the `syncsort` utility. You can use all of the options that are available to the SAS sort utility, such as the SORTEQ and NODUPKEY options. In some situations, you can improve your performance by using the NOEQUALS option. If you specify an option that is not supported by the host sort, then the SAS sort is used instead. For more information about all of the options that are available, see “SORT Procedure” in Base SAS Procedures Guide.
Limiting the Amount of Memory Available to PROC SORT

You can use the SORTSIZE= system option in the PROC SORT statement to limit
the amount of memory that is available to the SORT procedure. This option can
reduce the amount of swapping SAS must do to sort the data set.

Note: If you do not specify the SORTSIZE= option, PROC SORT uses the value of
the SORTSIZE system option. The SORTSIZE system option can be defined in the
command line or in the SAS configuration file.

Syntax of the SORTSIZE= Option

The syntax of the SORTSIZE= system option is as follows:

SORTSIZE=memory-specification

Specify memory-specification as one of the following values:

- $n$ specifies the amount of memory in bytes.
- $nK$ specifies the amount of memory in kilobytes.
- $nM$ specifies the amount of memory in megabytes.
- $nG$ specifies the amount of memory in gigabytes.

Default Value of the SORTSIZE= Option

The default SAS configuration file sets this option based on the value of the
SORTSIZE system option. To view the default value for your operating environment,
execute the following code:

```sas
proc options option=sortsize;
run;
```

You can override the default value of the SORTSIZE system option in one of the
following ways:

- by specifying a different SORTSIZE= value in the PROC SORT statement
- by submitting an OPTIONS statement that sets the SORTSIZE system option to
  a new value
- by setting the SORTSIZE system option in the command line during the
  invocation of SAS
Improving Performance with the SORTSIZE= Option

The SORTSIZE system option limits the amount of memory that is available to PROC SORT. In general, you should set the SORTSIZE= option to be no larger than the amount of memory that is available to the SAS process through the MEMSIZE option.

When the SORTSIZE= value is large enough to fit the entire data set in memory, you can achieve optimal sort performance if the amount of physical RAM available is as large as SORTSIZE=. If you do not have enough physical RAM, then your computer starts swapping the extra memory pages to disk and negates the performance gains of using memory.

If the entire data set to be sorted does not fit in the memory space that is allocated by SORTSIZE, SAS creates a temporary utility file to store the data. In this case, SAS uses a sort algorithm that is tuned to sort using disk space instead of memory. These temporary utility files are placed in the SAS Work location. However, these files can be placed in a different file system so that I/O is not impeded by using the UTILLOC system option.

If you can place the SAS data set that you want to sort in physical memory on your machine, then a sort in SAS is very efficient. Set SORTSIZE to be larger than the size of the data file. If you cannot fit the data file in physical memory, then set SORTSIZE to 1G or less. In addition, SORTSIZE should always be set to a value that is at least 8M smaller than MEMSIZE.

TAGSORT Option

The TAGSORT option in the PROC SORT statement is useful when there might not be enough disk space to sort a large SAS data set. When you specify the TAGSORT option, only the sort keys (that is, the variables specified in the BY statement) and the observation number for each observation are stored in the temporary utility files. The sort keys, together with the observation number, are referred to as tags. At the completion of the sorting process, the tags are used to retrieve the records from the input data set in sorted order. Thus, in cases where the total number of bytes of the sort keys is small compared with the length of the record, temporary disk use is reduced considerably.

You must have enough disk space to hold an additional copy of the data set (the output data set) and the utility file that contains the tags. By default, this utility file is stored in the SAS Work library. If this directory is too small, you can change this directory by using the WORK system option. For more information, see "WORK System Option: UNIX" on page 462.

Note: Note that while using the TAGSORT option might reduce temporary disk use, the processing time could be higher. However, on systems with limited available disk space, the TAGSORT option might enable data sets to be sorted in situations where that would otherwise not be possible.
Disk Space Considerations for PROC SORT

You need to consider the following information when determining the amount of disk space needed to run PROC SORT:

input SAS data set
PROC SORT uses the SAS input data set specified by the DATA= option.

Note: The input data option and output data options cannot both point to a CAS table.

output SAS data set
PROC SORT stores the output SAS data set in the location that is specified by the OUT= option. If you use the SAS single-threaded sort, and the OUT= option is not specified, PROC SORT stores the output SAS data set in the Work library.

Note: The input data option and output data options cannot both point to a CAS table.

utility file
The UTILLOC system option affects the storage location of the utility file only when the SAS multi-threaded sort is used. The SAS single-threaded sort still stores its utility file in the Work directory. Generally, for the single-threaded sort, the utility file is slightly larger than the uncompressed input SAS data set because additional sortkey data, derived from the BY variables, is included with each record. The utility file can be significantly larger than the uncompressed input SAS data set when BY variables comprise a large portion of an observation or when you use the SORTSEQ=LINGUISTIC option with character BY variables. The utility file can also double in size in extreme circumstances, such as when you have a very large input data set, very little memory available for sorting, or a large utility file page size.

When the SORT procedure invokes the multi-threaded sort, you can distribute multiple utility files to different locations. The utility file is similar in size to the uncompressed input SAS data set. Usually, only a single utility file of this size is required. However, in extreme circumstances, there might be up to two utility files of this size that are used. PROC SORT distributes the two utility files to the next two and least recently used locations.

Note: You can use the UTILLOC system option to specify a location in which applications can store utility files.

temporary output SAS data set
During the sort, PROC SORT creates its output in the directory specified in the OUT= option. If you do not specify OUT=, the output is created in the directory of the input SAS data set. The temporary data set has the same filename as the original data set, except it has an extension of .lck. After the sort completes successfully, the original data set is deleted, and the temporary data set is renamed to match the original data set. Therefore, you need to have enough available disk space in the target directory to hold two copies of the data set.
You can reduce the amount of disk space that is needed by specifying the OVERWRITE option in the PROC SORT statement. When OVERWRITE is specified, SORT, if possible, deletes the input data set before it attempts to write the replacement output data set. Deleting the input data set first can free storage space. This option should be used only with a data set that is backed up, or with a data set that you can reconstruct. For more information, see “SORT Procedure” in Base SAS Procedures Guide.

Performance Tuning for PROC SORT

How SAS Determines the Amount of Memory to Use

The MEMSIZE system option limits the amount of memory that is available to the SAS process. The SORTSIZE system option limits the amount of memory that is available to PROC SORT. The REALMEMSIZE system option specifies the amount of real (not virtual) memory that is made available to SAS.

Although memory settings below the default values for MEMSIZE and SORTSIZE might adversely affect sorting and SAS performance, making large amounts of memory available might be of no benefit. The key for determining whether additional memory might improve performance is whether the sort fits in memory. If the sorted file requires more memory than is allocated, then a SORTSIZE value in the range of 64–512M is generally the optimal value. SORTSIZE should always be set to a value that is at least 8M smaller than MEMSIZE.

For information about setting the REALMEMSIZE system option, see “REALMEMSIZE System Option: UNIX” on page 433.

Note: If you receive an out of memory error, then increase the value of MEMSIZE. For more information, see “MEMSIZE System Option: UNIX” on page 420.

Guidelines for Setting the REALMEMSIZE System Option

You can use the REALMEMSIZE system option with PROC SORT to determine how much memory to use. It is important that the REALMEMSIZE value reflects the amount of memory that is available on your system. For optimal performance, the maximum value for the memory setting for all of your applications (including file cache), should never exceed the amount of physical RAM on your computer. The default value for REALMEMSIZE is 80% of the MEMSIZE setting. If REALMEMSIZE is set too high, then PROC SORT might use more memory than is actually available. Using too much memory causes excessive paging and adversely impact system performance.

In general, REALMEMSIZE should be set to the amount of physical memory (not including swap space) that you expect to be available to SAS at run time. A good starting value is the amount of physical memory installed on the computer less the amount that is being used by running applications and the operating system. You can experiment with the REALMEMSIZE value until you reach optimum performance for your environment. In some cases, optimum performance can be achieved with a very low REALMEMSIZE value. A low value could cause SAS to use less memory and leave more memory for the operating system to perform I/O caching.
For more information, see “REALMEMSIZE System Option: UNIX” on page 433.

Using Other Options That Affect Performance

The THREADS system option controls whether threaded procedures use threads. It is available as both a system option and as a procedural override in PROC SORT.

The CPUCOUNT option is directly related to the THREADS option and defaults to the number of CPUs on your computer. Depending on your file system and the number of concurrent users, you might benefit from lowering the CPUCOUNT on machines that have many CPUs. When the value of CPUCOUNT equals ACTUAL, SAS returns the number of physical CPUs that are associated with the operating environment where SAS is executing.

The UTILLOC system option allows for the spreading of utility files, and is a good option for balancing I/O.

The DETAILS option, specified in the PROC SORT statement, causes PROC SORT to write messages to the SAS log detailing whether the sort was performed in memory. If the sort was not performed in memory, then the details that are written include the number of utility files and their sizes.

For more information about the THREADS, CPUCOUNT, and UTILLOC system options see SAS System Options: Reference.

Creating Your Own Collating Sequences

If you want to provide your own collating sequences or change a collating sequence provided for you, use the TRANTAB procedure to create or modify translation tables. For more information, see “TRANTAB Procedure” in SAS National Language Support (NLS): Reference Guide. When you create your own translation tables, they are stored in your Sasuser.Profile catalog. Your translation table overrides any translation table with the same name that is stored in the Host catalog.

Note: System managers can modify the Host catalog by copying newly created tables from the Profile catalog to the Host catalog. Then, all users can access the new or modified translation table.

If you are using the SAS windowing environment and want to see the names of the collating sequences that are stored in the Host catalog, issue the following command from any window:

catalog sashelp.host

If you are not using the SAS windowing environment, then issue the following statements to generate a list of the contents in the Host catalog:

proc catalog catalog=sashelp.host;
contents;
run;

Entries of type TRANTAB are the collating sequences.

To see the contents of a particular translation table, use the following statements:

proc trantab table=table-name;
list;
run;

The contents of collating sequences are displayed in the SAS log.
Specifying the Host Sort Utility

Introduction to Using the Host Sort

SAS supports one host sort utility on UNIX called `syncsort`. You can use this sorting application as an alternative sorting algorithm to the SAS sort. SAS determines which sort to use by the values that are set for the SORTNAME, SORTPGM, SORTCUT, and SORTCUTP system options.

Setting the Host Sort Utility as the Sort Algorithm

To specify a host sort utility as the sort algorithm, complete the following steps:

1. Specify the name of the host utility (`syncsort`) in the SORTNAME system option.
2. Set the SORTPGM system option to tell SAS when to use the host sort utility.
   - If you specify SORTPGM=HOST, then SAS always prefers to use the host sort utility.
   - If you specify SORTPGM=BEST, then SAS chooses the best sorting method (either the SAS sort or the host sort) for the situation.

Sorting Based on Size or Observations

The sort routine that SAS uses can be based on either the number of observations in a data set, or on the size of the data set. When the SORTPGM system option is set to BEST, SAS uses the first available and pertinent sorting algorithm based on the following order of precedence:

- host sort utility
- SAS sort utility

The SORTCUT system option is based on the number of observations in a data set. The SORTCUTP system option is based on the size of the data set. SAS looks at the values for the SORTCUT and SORTCUTP system options to determine which sort routine to use. If the number of observations is greater than or equal to the value of SORTCUT, SAS uses the host sort utility. If the number of bytes in a data set is greater than the value of SORTCUTP, SAS uses the host sort utility.

If SORTCUT and SORTCUTP are set to zero, SAS uses the SAS sort utility. If you specify both system options, and either condition is met, SAS uses the host sort utility.

When the following OPTIONS statement is in effect, the host sort utility (`syncsort`) is used when the number of observations is 500 or greater:

```sql
options sortpgm=best sortcut=500;
```

In this example, the host sort utility is used when the size of the data set is greater than 40M:

```sql
options sortpgm=best sortcutp=40M;
```
For more information about these sort options, see “SORTCUT System Option: UNIX” on page 444, “SORTCUTP System Option: UNIX” on page 445, and “SORTPGM System Option: UNIX” on page 449.

Changing the Location of Temporary Files Used by the Host Sort Utility

By default, the host sort utilities use the location that is specified in the -WORK option for temporary files. To change the location of these temporary files, specify a location by using the SORTDEV system option. Here is an example:

```plaintext
options sortdev="/tmp/host";
```

For more information, see “SORTDEV System Option: UNIX” on page 447.

Passing Options to the Host Sort Utility

To specify options for the sort utility, use the SORTANOM system option. For a list of valid options, see “SORTANOM System Option: UNIX” on page 443.

Passing Parameters to the Host Sort Utility

To pass parameters to the sort utility, use the SORTPARM system option. The parameters that you can specify depend on the host sort utility. For more information, see “SORTPARM System Option: UNIX” on page 448.

Specifying the SORTSEQ= Option with a Host Sort Utility

The SORTSEQ= option enables you to specify the collating sequence for your sort. For a list of valid values, see “SORT Procedure” in Base SAS Procedures Guide.

**CAUTION**

If you are using a host sort utility to sort your data, then specifying the SORTSEQ= option might corrupt the character BY variables if the sort sequence translation table and its inverse are not one-to-one mappings. In other words, for the sort to work, the translation table must map each character to a unique weight, and the inverse table must map each weight to a unique character.

If your translation tables do not map one-to-one, then you can use one of the following methods to perform your sort:

- Create a translation table that maps one-to-one. Once you create a translation table that maps one-to-one, you can easily create a corresponding inverse table using the TRANTAB procedure. If your translation table is not mapped one-to-one, then the following note appears in the SAS log when you try to create an inverse table:

  ```plaintext
  NOTE:  This table cannot be mapped one to one.
  ```

  For more information, see “TRANTAB Procedure” in SAS National Language Support (NLS): Reference Guide.
Use the SAS sort. You can specify the SAS sort using the SORTPGM system option. For more information, see “SORTPGM System Option: UNIX” on page 449.

Specify the collation order options of your host sort utility. See the documentation for your host sort utility for more information.

Create a view with a single BY variable. For an example, see “Example: Creating a View with a Single BY Variable” on page 517.

Note: After using one of these methods, you might need to perform subsequent BY processing using either the NOTSORTED option or the NOBYSORTED system option. For more information about the NOTSORTED option, see “BY Statement” in SAS DATA Step Statements: Reference. For more information about the NOBYSORTED system option, see “BYSORTED System Option” in SAS System Options: Reference.

Syntax: SORT Procedure: UNIX

Category: CAS
UNIX specifics: sort utilities available
See: “SORT Procedure” in Base SAS Procedures Guide

PROC SORT <option> <collating-sequence-option>;

<table>
<thead>
<tr>
<th>Statement</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROC SORT</td>
<td>Sort observations in a SAS data set by one or more variables</td>
</tr>
</tbody>
</table>

PROC SORT Statement: UNIX

Sorts observations in a SAS data set by one or more variables, and then stores the resulting sorted observations in a new SAS data set or replaces the original data set.

Syntax

PROC SORT <option> <collating-sequence-option>;;
Optional Argument

**option**

SORTSIZE=memory-specification

specifies the maximum amount of memory available to the SORT procedure. For more information about the SORTSIZE= option, see “SORTSIZE= Option” on page 508.

TAGSORT

stores only the BY variables and the observation numbers in temporary files. The TAGSORT option has no effect on a UNIX host that uses **syncsort**.

For more information about the TAGSORT option, see “TAGSORT Option” on page 509.

DETAILS

specifies that PROC SORT write messages to the SAS log detailing whether the sort was performed in memory. (This option is a statement option.)

If the sort was not performed in memory, then the details that are written to the SAS log include the number of utility files that were used and their sizes.

**Tip** Using the DETAILS option can help determine an ideal SORTSIZE value.

- “UTILLOC= System Option” in *SAS System Options: Reference*
Example: Creating a View with a Single BY Variable SORT Procedure: UNIX

This example uses a simple text file called attendees.txt as input for the IMPORT procedure. The file is a space-delimited text file that includes a list of names and ages. Here are the contents of the attendees.txt file:

Name  Age
Anne  35
ALBERT 10
JUAN  90
Janet 5
Bridget 23
BRIAN 45

The following example shows how to create a view by using a single BY variable. SAS uses the BEST argument in the SORTPGM system option to sort the data. By using BEST, SAS selects either the host sort or the SAS sort. (Sorting can also be performed by a DBMS when you use a SAS/ACCESS engine to define a libref.)

options sortpgm=best msglevel=i;

proc import datafile='./mydata/attendees.txt'
   dbms=dlm
   out=one
   replace;
   delimiter=' '\;
run;

data oneview / view=oneview;
   set one;
   Name1=upcase(name);
run;

proc sort data=oneview out=final(drop=name);
   by Name1;
run;

proc print data=final;
run;

Introduction to the !SASROOT Directory

When SAS is installed, its entire directory structure is located in a directory in your file system. This directory is called SASHOME. The SASHOME directory can be located anywhere in your file system.

- For SAS 9, the default location for SASHOME is /usr/local/SAS.
- For SAS Viya integrated with SAS 9.4M6, the default location for SASHOME is /opt/sas/spre/home.
- For SAS Viya only, the default location for SASHOME is /opt/sas/viya/home.

The traditional !SASROOT directory (SAS Foundation) is automatically installed in a subdirectory that is located in SASHOME.

- For SAS 9, the default directory for !SASROOT is SASHOME/SASFoundation/9.x, where x is the SAS release.
- For SAS Viya, the default directory for !SASROOT is $SASHOME/SASFoundation.

Note: Here, $SASHOME indicates an environment variable that contains the path to the SASHOME directory.

Contents of the !SASROOT Directory

The !SASROOT directory contains the files that are required to use SAS. This directory includes invocation points, configuration files, sample programs, catalogs, data sets, and executable files. You do not need to know the organization of these directories to use SAS.

If all available SAS products are installed on your system, the !SASROOT directory contains the files and directories that are listed in the following tables.

The Utilities Directory in UNIX Environments

The !SASROOT/utilities directory contains the following important subdirectories:

**man**

contains the online manual pages for SAS. “Installing Manual Pages” on page 528 describes how to make these pages accessible to users through the UNIX man command.

**bin**

contains the executable files for administrative tools. “Utilities in the /utilities/bin Directory” on page 528 describes some of the tools in this directory.

**src/auth**

contains source files and documentation for the UNIX Authentication API. The API enables administrators to add custom authentication methods to SAS authentication in UNIX environments. For more information, see “The UNIX Authentication API” on page 538.

The Utilities Directory in UNIX Environments
Installing Manual Pages

To be able to read the manual pages in the utilities/man directory, copy the files to the man1 subdirectory of the location of the other man files for your system. This location is usually /usr/man or /usr/local/man. Execute the UNIX man man command to determine the appropriate pathname for your system. When you have found the correct pathname, use the following command to copy the SAS man files:

```bash
cp -r sasroot/utilities/man/* pathname
```

*pathname* is the directory location of your system man files.

For example, the following command enables you to access online Help by copying the SAS man files from the SASHOME directory to the man1 file in your system’s man directory:

```bash
cp /usr/local/SASHOME/SASFoundation/9.4/utilities/man/* /usr/local/man/man1
```

After you issue this command, you can access online Help with the `man sas` command.

You can also add the directory to your system’s MANPATH environment variable if it has been previously defined, or you can set you own MANPATH environment variable,

Utilities in the /utilities/bin Directory

The following table briefly describes some of the tools in the /utilities/bin directory. You can use the UNIX man command for information about these utilities.

Table A20.1  Tools for the System Administrator

## Tool Name | Description
---|---
sas-services-daemon.init | System V initialization script
sas-services-daemon.service | system configuration file
sastcpd | TCP/IP access daemon
sasumgmt | obtains and transcodes or decodes the user name and password into Unicode. It then calls the SAS authorization service to authenticate the user. It then exits with an exit status that indicates the success or failure of the authentication.
saswujms | Japanese input server
setuid | directory
setuid.sh | script to set some commands to run as root
tkdef.so | the location where SASROOT and TKPATH are patched for SAS 9.4 (other executables are not patched as they were in previous SAS releases)

### SAS Usage Utilities: cleanwork

Deletes any leftover Work directories, utility directories, or both, whose associated SAS process has ended.

**cleanwork directory** `<-n > < -v > < -hostmatch > < -log logfile >`

**directory**

names the directory that contains the Work directory, the Utility directory, or both directories. That is, you can specify multiple directory paths in the cleanwork command. The directory name must match the value specified in the WORK system option or the value specified in the UTILLOC system option.

**Tip** Execute the cleanwork command as the root user. If a different user ID is used, then only files owned by that user ID are removed.

**-n** specifies that no entries should be removed. SAS lists the directories that contain files that can be removed, but those files are not removed.

**-v** specifies verbose output.
-hostmatch
   specifies the name of a host from which you can remove Work directories that
   might still be active in a Network File System (NFS).

-log logfile
   specifies that the output from cleanwork should be sent to a log file. The -log
   option is useful when you run cleanwork from a cron (scheduled) job.

   You provide the name of the log file (logfile) for the cleanwork output. The logfile
   name can include a path or only the filename. If no path is provided, the file is
   generated in the directory from which you called the cleanwork utility. Enclose
   the filename in single quotation marks if you use characters that are considered
   special by the shell.

Details

The cleanwork command removes any subdirectories that were assigned to the
Work library or directories assigned by the UTILLOC system option. The cleanwork
command removes only those files that are associated with defunct SAS processes.
Each subdirectory name has a format of the form:

SAS_workcode_nodename

SAS_utilcode_nodename

code
   is a 12-character code. The first four characters are randomly generated
   numbers. The next eight characters are based on the hexadecimal
   representation of the process ID of the associated SAS process. Files that are
   associated with active processes are not removed.

nodename
   specifies the name of the UNIX system where the SAS process is running.

For example, if you are working on nodename jupiter, then the cleanwork command
removes all directories with inactive processes on jupiter. The cleanwork command
does not remove a directory that is associated with an orphaned process if that
process is still active. In this case, you need to manually kill the process, and then
rerun cleanwork.

See Also

“Work Library” on page 69
manager has access to different information than a quality assurance manager. This is true even though each user accesses the same SAS system. The look and feel of the software might also vary based on the data and tasks that a specific user can access.

Here are the utilities that are used to implement authentication in SAS:

- SASUMGMT
- SASAUTH
- SAS-SERVICES-DAEMON
- SASPERM
- ELSSRV

These utilities are setuid processes that are owned by root. For more information about these processes, see *SAS Intelligence Platform: Application Server Administration Guide*. For more information about setuid processes, see *SAS Intelligence Platform: Installation and Configuration Guide*.

### SASUMGMT Utility

#### Overview

Use the SASUMGMT utility to validate that a user name and password is valid and that these credentials can be used for SAS authentication. Use this utility to debug any issues that pertain to a user's ability to authenticate. You also run this utility to ensure that a user has access to a specific file or directory.

The SASUMGMT utility is used during installation to validate the user names and passwords that are entered during initial server configuration. If these passwords are not verified during the installation process, then server start-up might fail. This situation results in a long process to determine the issue and correct it. Validating the passwords during the initial configuration ensures that all necessary users can authenticate into the server after it is running. During initial configuration, SASUMGMT also ensures that a user has access to the files and directories that they need when they run the server.

The SASUMGMT utility is stored in the !SASROOT directory of a standard SAS installation.

#### Syntax for SASUMGMT

Here is the syntax for SASUMGMT:

```
<sasroot>/utilities/bin/sasumgmt -u <username> -p <plain-text-password>
-u <username> -p {*}<encoded-password>
-u <username> -stdio
-read <pathname>
-write <pathname>
-execute <filename>
-re <filename>
-rw <filename>
-rwe <filename>
```
There are multiple ways to enter the password for a user. You can specify it in plain text, with a provided SAS encoded string, or through standard input. For more information about encrypting password values, see “PWENCODE Procedure” on page 538.

Results of SASUMGMT

The SASUMGMT utility provides the following results. Return codes are shown in parentheses:

- (0) The user name and password were authenticated. (There is no output on the command line.)
- (1) Access denied. The user name and password were not authenticated.
- (2) The password has expired.
- (3) The SASAUTH service is not setuid root as required by the installation.
- (4) The TKSECURE authentication service encountered a problem.
- (5) There was a problem initiating the thread.
- (6) A user name was not supplied.
- (7) A password was not supplied.
- (8) There was failure reading the password from standard input.
- (9) Insufficient arguments were supplied to the program.
- (10) The user name or password could not be transcoded into UNICODE.
- (11) Memory could not be allocated to perform the authentication.
- (12) The password could not be decoded.
- (13) The thread handle could not be obtained.
- (14) The user does not have appropriate access to the pathname.
- (15) The filename was omitted from the argument list when specifying Read or Write permission.

SASAUTH Utility

Overview of SASAUTH

The SASAUTH utility is used by SAS 9 servers to perform authentication for connecting clients. The default authentication method is via the host operating system. Most sites that use host operating system authentication deploy a shadow password file configuration. To read the password entries that contain the password from the shadow password file, the calling user ID must be root. If the SASAUTH executable is not a setuid process that is owned by root, then the system is not able to authenticate users that attempt to access the SAS servers.

The SASAUTH utility is used to authenticate access to a SAS server, such as the workspace server, SAS Metadata Server, SAS Stored Process Server, or SAS/SHARE server.
Changing the Authentication Method

The administrator is allowed to change the authentication from the host operating system to another method of authentication, such as PAM or LDAP. The file sasauth.conf is used by SASAUTH to manage the authentication requirements. The sasauth.conf file must reside in the same directory as SASAUTH.

To change the authentication method, change the line that contains `methods=pw` in the sasauth.conf file. Here are the available methods:

- **methods=pw**
  - specifies to use standard `/etc/password` or `/etc/shadow` authentication. On some hosts, this includes protected password databases or OS-provided enhanced security.

- **methods=pam**
  - specifies to use PAM for authentication. The password database is also used to determine the user’s UID and GID. The pam.conf file must be configured properly for SASAUTH.

- **methods=ldap**
  - specifies to use LDAP authentication. You must define the LDAP parameters.

- **methods=ext**
  - specifies to use a customer authentication method. This method is built using the authentication kit, which is available from SAS Technical Support.

Logging SASAUTH Output

The sasauth.conf file enables the administrator to log SASAUTH operations. To turn on logging, remove the ‘#’ in front of the appropriate log variable and provide a location for the log file. The lines with the log variables look like these:

```bash
#debugLog=/tmp/sasauth-debug.log
#accessLog=/tmp/sasauth-access.log
#errorLog=/tmp/sasauth-error.log
#logOwner=0
debugNoPasswords=true
```

Here are the log file descriptions and definitions for authentication-related variables:

- **debugLog**
  - specifies the path for the debugging log. As a best practice, do not use debugLog regularly in a production environment, because the log can become very large. This file is readable by the root user, unless an alternative file owner is specified for the logOwner variable. (See below.)

- **accessLog**
  - specifies the path for the access log. All authentication operations and the corresponding result (ok, expired, or error) are logged in this file. This file is readable by anyone.

- **errorLog**
  - specifies the path for the error log. If this variable is not specified, errors are sent to syslog.

- **logOwner**
  - specifies the UID of the owner of the debug log file. By default, the debug log owner is the root user (UID=0).
debugNoPasswords

is a Boolean variable that specifies whether to write passwords in the debug log. By default, passwords are not written to the debug log (debugNoPasswords=true).

This figure shows the output from two authentication attempts. The first succeeds, but the second is an unknown user.

Figure A20.1  Sample sasauth-access.log File

```
20140202-09:44:40 Authenticated user user1 (pw).
20140202-09:44:54 Unknown user mickey.
```

This figure shows sample output for the sasauth-debug.log file.

Figure A20.2  Sample sasauth-debug.log File

```
20140202-09:44:40 Adding auth method pw
20140202-09:44:40 Initialized 1 methods.
20140202-09:44:40 Authenticating user user1 via pw
20140202-09:44:40 Authenticating user user1 via password database
20140202-09:44:40 Using crypt()/bignumcrypt()/crypt6() encryption.
20140202-09:44:40 Checking for expiration.
20140202-09:44:40 Getting user's group memberships
20140202-09:44:40 User sas1 in 2 groups.
20140202-09:44:40 Authenticating user user1 (pw).
20140202-09:44:54 Authenticating user mickey via pw
20140202-09:44:54 Authenticating user mickey via password database
20140202-09:44:54 User not in /etc/passwd.
20140202-09:44:54 Unknown user mickey.
20140202-09:44:54 Request failed: 'Unknown user.'
```

SAS-SERVICES-DAEMON Utility

Overview of SAS-SERVICES-DAEMON

The SAS-SERVICES-DAEMON utility is similar to the SASAUTH utility. The SAS-SERVICES-DAEMON utility is used to perform authentication for connecting clients. SAS-SERVICES-DAEMON differs from SASAUTH because it enables multiple authentication requests that are handled concurrently. SAS-SERVICES-DAEMON runs independently of any other SAS processes. SAS-SERVICES-DAEMON should be started as a daemon when SAS starts. It should be started before any SAS processes or SAS servers, and it must be run under the root user ID. However, unlike SASAUTH, SAS-SERVICES-DAEMON does not require the setuid bit to be set.

Note: The SAS-SERVICES-DAEMON utility is supported for Linux environments only.

The SASAUTH utility runs by default. However, you can enable the SAS-SERVICES-DAEMON utility by setting the SAS_USE_SASSD= environment
variable to 1 in the level_env_usermods.sh file. That is, include the following line in the level_env_usermods.sh file:

```bash
export SAS_USE_SASSD=1
```

For more information, see your SAS installation and configuration documentation for UNIX at [support.sas.com](http://support.sas.com).

**Changing the Authentication Method**

The default authentication method is based on the host operating system. Most sites that use host operating system authentication deploy a shadow password file configuration. An administrator is allowed to change the authentication method. The file sas-services-daemon.conf is used by SAS-SERVICES-DAEMON to manage the authentication requirements. The sas-services-daemon.conf file must reside in the same directory as SAS-SERVICES-DAEMON.

To change the authentication method, change the line that contains `methods=pw` in the sas-services-daemon.conf file. Here are the available methods:

```bash
methods=pw
```

specifies to use standard `/etc/passwd` or `/etc/shadow` authentication.

```bash
methods=pam
```

specifies to use PAM for authentication. The password database is used to determine the user’s UID and GID. The SAS-SERVICES-DAEMON PAM configuration file must be named sas-services-daemon. Store this file in `/etc/pam.d`.

**Specifying the Number of Threads**

An administrator can set the number of threads to use for concurrent authentication requests. Set the `numThreads` value in the sas-services-daemon.conf file to change the number of threads that process authentication requests. The default value for `numThreads` is 4 and the maximum value is 32.

**SASPERM Utility**

The SASPERM utility performs host authorization checks against files on disk in the SAS/SHARE Server and SAS Stored Process Server. This process uses the `stat()` system call and the `access()` system call to determine whether a user should have access to a given file. The utility must switch identity to the requesting client to perform these calls as the user that is requesting the access. Therefore, calls to SASPERM must be run as root.

**ELSSRV Utility**

**Overview**

The object spawner uses a setuid root utility called ELSSRV to launch processes under the identity of the requesting client (a standard workspace server) or a multi-
user credential (a load-balanced stored process server and a pooled workspace server). The call to ELSSRV must be as the root user to switch identity to another user.

**Note:** If you run the UNIX `ps -ef` command, the ELSSRV process is displayed as `sasels` on a machine that is not a SAS server and as `saslesrv` on a SAS server. The path of execution is not provided.

In the case of a standard workspace server, the client provides host credentials for the user that requests a SAS process, such as a query or an ETL process, from the spawner. The spawner host authenticates the client and receives confirmation of valid credentials from SASAUTH. In addition, SASAUTH returns the UNIX user ID and the list of groups that are associated with that user. The ELSSRV utility launches the workspace server under the client identity so that the process runs with the host authority of the requesting client. The ELSSRV process also requires the credentials to do a second validation of the user authority to prevent misuse of the ELSSRV process.

In the case of a SAS Stored Process Server or a SAS Pooled Workspace Server, the spawner uses ELSSRV to launch processes under a chosen credential that is stored in metadata and that is associated with the server. For a SAS Stored Process Server, the clients are authenticated by the host before they can run a SAS process on one of the servers. The pooled workspace servers do not require host authentication because processes that run on these servers are in a much more controlled environment. The SAS Stored Process Server host authenticates the connecting clients by using SASAUTH and obtains the clients user ID and associated groups.

**Logging with ELSSRV**

You can use environment variables to enable logging and debugging of the ELSSRV process. For example, logging is useful when a SAS BI Client installation is unable to launch a SAS BI Server or when a server is exiting or timing out for an unknown reason. The `els` log file provides detailed information about what servers are requesting and about the exit status of the servers.

The `ELSDEBUG` environment variable instructs the ELSSRV process to log its activity. This is often useful to debug `systask` commands, launching a SAS server, or using the `&` command or filename pipe.

On a csh shell, you enable the ELSDEBUG environment variable on the command line with this syntax:

```
setenv ELSDEBUG 1
```

On a ksh shell, you enable this ELSDEBUG environment variable on the command line with this syntax:

```
export ELSDEBUG=1
```

The `ELSLOG` environment variable enables you to specify the path and base filename for the output log file. The name of the log file is appended with “.els.<process-ID>”. For example, if you specify your path as `/tmp/techsupport`, then the output file for process 2456 would be `/tmp/techsupport.els.2456`. 

---

*Authentication Utilities*
Restricting Access to Ports

The server communicates the exit status of processes through a socket connection. By default, the port number is obtained from the operating system. To limit the range of the port values that can be selected, use the MINPORT and MAXPORT options. This enables you to set a range of port numbers for the ELSSRV utility. Specify these options as follows:

```
-minport <minimum-port-value>
-maxport <maximum-port-value>
```

If a port cannot be found within this range, then TKELS fails to load and SAS subsequently fails to start. The maximum possible port number is $64^{1024-1}$.

PWENCODE Procedure

Use the PWENCODE procedure to encode a password to be given to SAS authentication. This procedure provides multiple methods to create encrypted values for user passwords. The following example shows results from the SAS002 encryption algorithm. The code to call the PWENCODE procedure specifies `in='my password'`, which is masked in the log. The log shows the resulting encrypted value.

```
1 proc pwencode in=XXXXXXXXXXXX method=sas002;
2 run;
3
```

```
[SAS002]68B279564BD2695538CDCDB301E8A357563480B0
```

The supported encoding methods include:

- SAS001, which uses the Base64 binary-to-text encoding scheme to encode passwords.
- SAS002 (or sasenc), which uses a 32-bit key to encode passwords. This is the default SAS encryption method.
- SAS003, which uses a 256-bit key to encode passwords. This Advanced Encryption Standard is supported in SAS/SECURE.

SAS001 and SAS002 are supplied with Base SAS.

The UNIX Authentication API

The UNIX Authentication Application Programming Interface (API) is a set of predefined routines that provide user authentication, identification, and permissions verification for SAS when running in UNIX environments. The source files provide the ability to add site-specific behavior to the authentication/identification/permissions validations process. Administrators that need to implement custom behaviors should contact SAS Technical Support.
Overview of SAS Versions

Your SAS image is one of thousands of possible executable images of SAS software. Each SAS image has a signature that includes the release level, relevant hot fixes, the product name, and even the development group that provided the image. Included with your software are tools that can identify the specifics about the SAS image that was installed at your site. If you have an issue with SAS, it is very important to be able to provide the specifics of your SAS image to SAS Technical Support.

There are two methods to obtain the image signature for your instance of SAS:

- VERCON utility, which is available from the command line
- TSLVL function, which is available within a SAS program

VERCON Utility

About the VERCON Utility

The VERCON utility is a stand-alone executable that you can run for your SAS image. This utility provides detailed information about the specifics of your installation, including the release, hot fixes, and maintenance images that were used as part of your SAS instance.

Syntax for VERCON

Here is the syntax to call the VERCON utility:

```
<!SASROOT>/utilities/bin/vercon <-l output-file> <- options> image(s)
```

Use the `-l output-file` argument to specify a filename for output. If you do not specify this argument, the default is standard output.

You can specify one or more of the following options. These options are not case sensitive.

- `-b` Print product: dvd/script/scriptname.bld. This can be used with `-i` to print the information about the image.
- `-d` Print the time at which the image was built in date and time format.
- `-f` Do not format the output.
- `-h` Print hot fix information.
- `-i` Print information about the image.
- `-p` Print the product name.
–q Do not print the image name.
–s Print the version information.
–t Print the track name.

At the end of the command, specify one or more images to provide version information for. If there are not too many, specify the images by name, separated by spaces. If the number of images is large, you can request information for all images in a directory that you specify. In this case, specify the directory as `-dir directory`.

**VERCON Examples**

By default, VERCON prints the most relevant information that is embedded for a given image. Here is the default output for VERCON run on the executable tkmemtst.so. The information provided includes the date on which the image was built, the product name, the release track, and the group that provided the image.

*Figure A20.3 Default VERCON Output*

```bash
% vercon tkmemtst.so

[ 1] ./tkmemtst.so PortDate : 9.03.01B0D11092009
    Track : dev/mva-v940
    Epoch Time : 1257879451
    Date : Tue Nov 10 13:57:31 2009
    Product Name : test
    Script Name : tkmemtst
    Script DVD : tktest
```

Here are some additional examples that show different combinations of options and the resulting output. Note in the last example that an error is displayed if the information for a file cannot be extracted.
### TSLVL Function

**About the TSLVL Function**

The TSLVL function runs inside a DATA step in a SAS program. This function returns the same information as the VERCON utility. You provide the image name as the first argument and any options as the second argument. Enter each argument within quotation marks.

Here are the available options that you can request. Options are not case sensitive.

- **A** Additional track information
- **D** Port date (for example, 9.03.01B0D02282010)
- **E** Number of seconds since January 1, 1970 (UNIX date). Note that SAS dates are based on the number of second since January 1, 1960.
- **H** Hot fix information
- **I** Image description
- **M** Maintenance release information
- **P** Product number
- **T** SAS track information

The output for the TSLVL function returns one character string for each requested information item, separated by commas to facilitate parsing the results.
If any information for an image is not available, you might receive the following errors:

- `ImageNotLoaded`—indicates that the requested image is not loaded
- `VersionNotFound`—indicates that version information could not be found
- `NotAvailable`—indicates any other problems obtaining version information

**TSLVL Example**

The following example calls the TSLVL function twice. The first instance results in the release number, SAS 9.4 Technical Support level 1 Maintenance level 5. This was the sixth release of SAS 9.4. The second instance requests the track, the port date, and the UNIX time at which the image was built. This image was built in the main development track for SAS 9.4M5 on April 22, 2018.

```sas
1 2 data x;
 3  y=tslvl('sasxkern');
 4    put y=;
 5  a=tslvl('sasxkern','tde');
 6    put a=;
 7  run;
```

y=9.04 TS1M5
a=dev/mva-v940m5b,9.04.01M5P04222018,1524439845

NOTE: The data set WORK.X has 1 observations and 2 variables.

Text-Editing Commands for SAS Windowing Environment

Commands that are specific to the text editor are called text-editing commands because they perform editing functions in windows. Text-editing commands can be one of two types:

- line commands
- command-line commands

Most line commands rearrange or reformat text. They perform tasks such as moving, deleting, copying, and aligning lines or blocks of text. Command-line commands, in addition to rearranging and reformatting text, perform other tasks such as reversing the effects of commands or changing the default case of text.

This section describes commands that you can use in the UNIX environment, but that are not specific to UNIX. You can use these commands in any operating environment that supports text-editing commands.

Dictionary

AUTOADD Command

Controls automatic line addition.

Category: Text Editing, Command-Line Command

Syntax

**AUTOADD <ON | OFF>**

Without Arguments

The AUTOADD command is toggled ON or OFF. Issue the command once to reverse the current setting. If the current setting is ON, then issuing the AUTOADD command changes the setting to OFF. If the current setting is OFF, then issuing the AUTOADD command changes the setting to ON.
Required Arguments

**ON**
- turns on the AUTOADD command in the window so that lines are added automatically.

**OFF**
- turns off the AUTOADD command in the window so that lines are not added automatically.

Details
The AUTOADD command controls whether blank lines are added as you scroll past existing text. The number of lines that are added is determined by the setting of the VSCROLL command, which determines the default scroll amount forward or backward.

See Also

**Commands:**
- “AUTOFLOW Command” on page 545
- “AUTOSPLIT Command” on page 547
- “AUTOWRAP Command” on page 548

---

**AUTOFLOW Command**

Controls whether text is flowed when it is included, copied, or pasted.

**Category:** Text Editing, Command-Line Command

**Syntax**

**AUTOFLOW <ON | OFF>**

**Without Arguments**

The AUTOFLOW command is toggled on and off. Issue the command once to reverse the current setting. If the current setting is ON, then issuing the AUTOFLOW command changes the setting to OFF. If the current setting is OFF, then issuing the AUTOFLOW command changes the setting to ON.

**Required Arguments**

**ON**
- turns on the AUTOFLOW command in the window so that text flows when it is inserted in the window.

**OFF**
- turns off the AUTOFLOW command in the window so that text retains its previous position when it is inserted in the window.
Details
The AUTOFLOW command controls whether text inserted with the INCLUDE, PASTE, or COPY command automatically flows. When text is flowed, the left and right boundaries are determined by the settings that were specified with previous executions of the INDENT and BOUNDS commands. The AUTOFLOW command controls all text that is inserted in the window. It does not stop at paragraph boundaries.

Comparisons
The AUTOFLOW command controls whether text inserted in the window flows. The TF command flows text that is already in the window.

See Also

Commands:
- “AUTOSPLIT Command” on page 547
- “AUTOWRAP Command” on page 548
- “BOUNDS Command” on page 549
- “INDENT Command” on page 560
- “TF Command” on page 576

AUTOSCROLL Command
Specifies how often the Log and Output windows scroll to display output.
UNIX specifics: valid arguments and default values

Syntax
AUTOSCROLL <n>

Optional Argument

n specifies the number of lines that the window should scroll when it receives a line of data that cannot fit.

Details
The AUTOSCROLL command controls the scrolling of lines as they are written to the Log and Output windows. The default value for AUTOSCROLL in the Log and Output windows is 1. Processing is slower when AUTOSCROLL displays one line at a time. To expedite processing, you can specify a greater AUTOSCROLL value in your autoexec.sas file. Specifying a value of 0 optimizes processing and results in the fastest scrolling (similar to jump scrolling in xterm windows). To add the AUTOSCROLL command to your autoexec.sas file, you must use the DM
command. The following example maximizes scrolling in both the Log and Output windows:

```
dm 'output; autoscroll 0; log; autoscroll 0; pgm;';
```

---

**AUTOSPLIT Command**

Controls whether text is split at the cursor when you press Enter, or when you are at a carriage return.

**Category:** Text Editing, Command-Line Command

**Syntax**

```
AUTOSPLIT <ON | OFF>
```

**Without Arguments**

The AUTOSPLIT command acts is toggled on and off. The first time you issue the AUTOSPLIT command, it reverses the current setting. If the current setting is ON, then issuing the AUTOSPLIT command changes the setting to OFF. If the current setting is OFF, then issuing the AUTOSPLIT command changes the setting to ON.

**Optional Arguments**

- **ON**
  - turns on the AUTOSPLIT command in the window so that when you press Enter, or when you are at a carriage return, text automatically splits at the cursor.

- **OFF**
  - turns off the AUTOSPLIT command in the window so that when you press Enter, or when you are at a carriage return, text does not automatically split at the cursor.

**Details**

The AUTOSPLIT command controls whether text is split at the cursor when you press Enter, or when you are at a carriage return. All text on the line, starting with the character on which the cursor is resting, moves to the left margin of the next line. The cursor is repositioned so that it rests on the first character of the new line.

**Comparisons**

Entering a carriage return with the AUTOSPLIT command turned on is identical to issuing the TS command with the default numeric argument of 1. The results of a carriage return with the AUTOSPLIT command turned on can be reversed by the TC command or undone with the UNDO command.

**See Also**

**Commands:**

- "AUTOSCROLL Command" on page 546
AUTOWRAP Command

Controls whether text is wrapped when it is included, copied, or filed.

Category: Text Editing, Command-Line Command

Syntax

AUTOWRAP <ON | OFF>

Without Arguments

The AUTOWRAP command is toggled on or off. The first time you issue the AUTOWRAP command, it reverses the current setting. If the current setting is ON, then issuing the AUTOWRAP command changes the setting to OFF. If the current setting is OFF, then issuing the AUTOWRAP command changes the setting to ON.

Optional Arguments

ON

turns on the AUTOWRAP command in the window so that text is wrapped when it is inserted in the window, or when it is moved to an external file.

OFF

turns off the AUTOWRAP command in the window. Depending on the line length, text can be truncated as it is inserted in the window, or when it is moved to an external file.

Details

When the AUTOWRAP command is turned on, you can use the INCLUDE or COPY commands. These commands can insert a file, which has a line length that exceeds the boundaries of the window, in a window. The text in the file is not truncated. Instead, lines in the file are split at word boundaries. Conversely, the AUTOWRAP command enables you to use the FILE command to send text, which has a line length that exceeds the boundaries of a file, to an external file. The text in the file is not truncated. Lines are split at word boundaries. When the AUTOWRAP command is turned off, text can be truncated depending on the line length of the text and of the window or file.

See Also

Commands:

- "AUTOFLOW Command" on page 545
- "AUTOSPLIT Command" on page 547
BOUNDS Command

Sets left and right boundaries when text is flowed.

Category: Text Editing, Command-Line Command

Syntax

BOUNDS <left right>

Without Arguments

The BOUNDS command displays a message identifying the current boundary settings.

Optional Arguments

left
  sets the left boundary by column position.

right
  sets the right boundary by column position.

Details

The BOUNDS command resets the left and right boundaries for text. Text is reset by column position and must already be in the window and flowed with the TF command. The BOUNDS command sets the left and right boundaries for text inserted in the window with the INCLUDE, COPY, and PASTE commands when the AUTOFLOW command is turned on. When the AUTOFLOW command is turned on, the left boundary setting is maintained when text is split with the TS command.

For example, specify the following command if you want the text flowed between columns 10 and 60:

```
bounds 10 60
```

Each time text is flowed after this BOUNDS command is issued, the text is flowed between spaces 10 and 60. The text is flowed until you issue another BOUNDS command, or the INDENT command is set to ON.

Setting the INDENT command to ON always overrides the current left boundary setting. To ensure that the left boundary setting is used, set the INDENT command to OFF.

Comparisons

The BOUNDS command affects the behaviors of the TF and TS commands. The BOUNDS command is similar to the INDENT command because both can set the left boundary. However, the BOUNDS command can set the right boundary. When text is flowed, setting the INDENT command to ON always sets the left boundary, which overrides the left boundary that is set by the BOUNDS command.
C Command

Copies one line of text.

Category: Text Editing, Line Command

Syntax

\[ \text{C} \]

intervening text

\[ \text{A} | \text{B} \]

Without Arguments

The C command copies one line of text to a new position anywhere in a window.

Required Arguments

\[ \text{A} \]

marks the target position of the line of text to be copied; in this case, after the position where the A argument is entered. You can place the A argument either before or after the line to be copied.

\[ \text{B} \]

marks the target position of the line of text to be copied; in this case, before the position where the B argument is entered. You can place the B argument either before or after the line to be copied.

Comparisons

The C and CC commands enable you to specify a target position for the line of text anywhere in the window. The R and RR commands repeat the line or block of text immediately after it first appears.

See Also

Commands:

- “CC Command” on page 552
CAPS Command

Changes the default case of text.

Category: Text Editing, Command-Line Command

Syntax

`CAPS <ON | OFF>`

Without Arguments

The CAPS command is toggled on and off. The first time you issue the CAPS command, it reverses the current setting. If the current setting is ON, then issuing the CAPS command changes the setting to OFF. If the current setting is OFF, then issuing the CAPS command changes the setting to ON.

Optional Arguments

**ON**

turns on the CAPS command. The case of characters that you enter after you turn on the CAPS command is uppercase. Character strings for the FIND and CHANGE commands are also translated into uppercase unless they are enclosed in quotation marks.

**OFF**

turns off the CAPS command. The case of characters that you enter after you turn off the CAPS command is unchanged.

Details

The CAPS command changes the case for text not yet entered, or for text that is modified in a window. If you specify CAPS ON and enter text, the text is changed to uppercase as soon as you press Enter. The setting remains in effect for a window until the SAS session ends, or until the setting is changed by another CAPS command. You can use the WSAVE command to save the setting of the CAPS command beyond your current SAS session.

Comparisons

The CAPS ON command is similar to the CU and CCU commands, and to the CL and CCL commands, which change the case of existing text. However, the CAPS command changes the default case of text, not the case of existing text.

See Also

Command:
CC Command

Copies a block of lines of text.

Category: Text Editing, Line Command

Syntax

CC

block of text

CC

intervening text

A | B

Without Arguments

The CC command copies a block of lines of text to a new position anywhere in a window.

Required Arguments

A

marks the target position of the lines of text to be copied; in this case, after the position where the A argument is entered. You can place the A argument either before or after the lines to be copied.

B

marks the target position of the lines of text to be copied; in this case, before the position where the B argument is entered. You can place the B argument either before or after the lines to be copied.

Details

The C and CC commands enable you to specify a target position for the lines of text anywhere in the window. The R and RR commands repeat the block of lines of text immediately after it first appears.

Commands:

- “C Command” on page 550
- “R Command” on page 571
CCL Command
Changes all characters in designated lines of text to lowercase.
Category: Text Editing, Line Command

Syntax
CCL
block of text
CCL

Without Arguments
The CCL command changes to lowercase all characters in a block of lines of text.

Details
The CL and CCL commands change existing text to lowercase. The CAPS OFF command makes the default case of text lowercase, which changes the case of new, inserted text. The CU and CCU commands, which change existing text to uppercase, accomplish the opposite of the CL and CCL commands.

See Also
Commands:
- “CAPS Command” on page 551
- “CCU Command” on page 553
- “CL Command” on page 554
- “CU Command” on page 555

CCU Command
Changes all characters in a designated block of lines of text to uppercase.
Category: Text Editing, Line Command

Syntax
CCU
block of text
CCU

Without Arguments

The CCU command changes to uppercase all characters in a block of designated lines of text.

Details

The CU and CCU commands are similar to the CAPS ON command. The CU and CCU commands change existing text to uppercase. The CAPS ON command makes the default case of text uppercase, which changes the case of new, inserted text. The CL and CCL commands, which change existing text to lowercase, accomplish the opposite of the CU and CCU commands.

See Also

Commands:
- “CAPS Command” on page 551
- “CCL Command” on page 553
- “CL Command” on page 554
- “CU Command” on page 555

CL Command

Changes all characters in a designated line of text to lowercase.

Category: Text Editing, Line Command

Syntax

CL <n>

Without Arguments

The CL command changes to lowercase all characters in a designated line of text.

Optional Argument

n

specifies the number of lines of text to be changed to lowercase. Follow the n argument with a space.

Details

The CL and CCL commands change existing text to lowercase. The CAPS OFF command makes the default case of text lowercase. The case of new, inserted text
is changed. The CU and CCU commands, which change existing text to uppercase, accomplish the opposite of the CL and CCL commands.

---

**CU Command**

Changes all characters in a designated line of text to uppercase.

**Category:** Text Editing, Line Command

**Syntax**

```
CU <n>
```

**Without Arguments**

The CU command changes to uppercase all characters in a designated line of text.

**Optional Argument**

```
<n>
```

specifies the number of lines of text to be changed to uppercase. Follow the `n` argument with a space.

**Details**

The CU and CCU commands are similar to the CAPS ON command. The CU and CCU commands change existing text to uppercase. The CAPS ON command makes the default case of text uppercase, which changes the case of new, inserted text. The CL and CCL commands, which change existing text to lowercase, accomplish the opposite of the CU and CCU commands.

See Also

**Commands:**

CURSOR Command

Moves the cursor to the command line.

Category: Text Editing, Command-Line Command

Syntax

CURSOR

Without Arguments

The CURSOR command moves the cursor to the command line. The CURSOR command is designed to be executed with a function key.

Details

The CURSOR command can be used interchangeably with the Home key.

Comparisons

The CURSOR command has the same results as pressing the Home key.

D Command

Deletes a designated line.

Category: Text Editing, Line Command

Syntax

D <n>

Without Arguments

The D command deletes only the designated line.

Optional Argument

n

specifies the number of lines to delete. Follow the n argument with a space.

See Also

Commands:
DD Command

Deletes a designated block of lines.

Category: Text Editing, Line Command

Syntax

DD

block of lines

DD

Without Arguments

The DD command deletes a block of lines of text.

See Also

Commands:

- “D Command” on page 556

DICT Command

Includes, releases, and creates an auxiliary dictionary.

Category: Text Editing, Command-Line Command

Syntax

DICT INCLUDE dictionary-name | FREE dictionary-name | CREATE dictionary-name <size>

Required Arguments

INCLUDE dictionary-name

makes the auxiliary dictionary that is specified available in the current SAS session. Only a one-level name is accepted. The Sasuser.Profile catalog is checked first for the dictionary. Then, the Sashelp.Base catalog is checked. If the auxiliary dictionary is not found, SAS issues an error message. If the auxiliary dictionary is made available from the Sashelp.Base catalog, no changes to it are saved. If it is made available from the Sasuser.Profile catalog, changes to it are saved.
FREE *dictionary-name*
releases the auxiliary dictionary that is specified. A newly created dictionary is not saved in the Sasuser.Profile catalog until you issue the DICT command with the FREE argument, or you end the current interactive windowing task. If the auxiliary dictionary has been modified, the changes are saved when you issue the DICT command with the FREE argument. These changes are saved unless the auxiliary dictionary was made available from the Sashelp.Base catalog.

CREATE *dictionary-name*
creates a new auxiliary dictionary as specified. The dictionary is initially empty. When the dictionary is released, it is saved in the Sasuser.Profile catalog. Only a one-level name is accepted.

Optional Argument

*size*
specifies the size in bytes of the auxiliary dictionary. The default is 9,808 bytes.

Details

The DICT command includes, releases, and creates an auxiliary dictionary. The SPELL command checks spelling and flags unrecognized words. In addition, the SPELL command can create and update dictionaries.

See Also

Commands:

- “SPELL Command” on page 573

---

**FILL Command**

Places fill characters beginning at the current cursor position.

Category: Text Editing, Command-Line Command

Syntax

FILL *<fill-character>* *<n>*

Without Arguments

The FILL command displays a message identifying the fill character and the number of its repetitions.

Optional Arguments

*<fill-character>*
specifies a customized character that must be enclosed in single quotation marks. The fill character remains in effect until you change it.
specifies the exact number of fill characters. The number remains in effect until you change it.

Details

The FILL command places fill characters beginning at the current cursor position. The fill characters extend to the end of a line, or to the space before the next non-blank character, whichever occurs first. By default, the fill character is usually an underscore or hyphen. If you use the FILL arguments, you can change the fill character and the number of repetitions.

The FILL command is most easily issued with a function key. To place the fill characters at the cursor position, set one of your function keys to issue the FILL command. Move the cursor to a Program Editor field, and then press the function key. The fill characters are displayed.

The following example shows how you can change the default. Issuing the following command makes the default become 10 question marks:

    fill '?' 10

The changed fill character is in effect for the duration of your SAS session, or until you change it. You can use the WSAVE command to permanently save the setting.

---

**I Command**

Inserts one or more blank lines.

**Category:** Text Editing, Line Command

**Syntax**

    I <A | B> <n>

**Without Arguments**

The I command inserts one or more blank lines immediately after the line on which you issued the command.

**Optional Arguments**

**A**

inserts one or more blank lines immediately after the line on which you issued the command. You cannot have any characters between the I command and the A argument.

**B**

inserts one or more the blank lines immediately before the line on which you issued the command. You cannot have any characters between the I command and the B argument.

**n**

specifies the number of blank lines to insert. Follow the n argument with a space. If you use the A or B argument, the n argument is specified last. For example, if
line 00009 contains a PROC PRINT statement, the following I command specifies that you want to insert three blank lines before the line of text:
ib3  9 proc print data=final.educ;

Details
The I command inserts one or more blank lines. By default, the lines are blank. You can define content with the MASK command. The I command is most easily issued with a function key.

Comparisons
You can use the MASK command with the I command. The I command inserts one or more blank lines, which can include content set by the MASK command.

See Also

**Commands:**
- "MASK Command" on page 568

---

**INDENT Command**

Retains left margin indentation when text is flowed.

Category: Text Editing, Command-Line Command

**Syntax**

`INDENT <ON | OFF>`

**Without Arguments**
The INDENT command is toggled on or off. The first time you issue the INDENT command, it reverses the current setting. If the current setting is ON, then issuing the INDENT command changes the setting to OFF. If the current setting is OFF, then issuing the INDENT command changes the setting to ON. When you reissue the INDENT command, it returns to the previous setting.

**Optional Arguments**

**ON**
turns on the INDENT command in the window.

**Tips**
The INDENT ON command indents all lines.

When the INDENT command is turned on and you issue the TF command, all of the lines in the paragraph are indented the same as the first line in the paragraph.
OFF

  turns off the INDENT command in the window.

Details

The INDENT command specifies that the current left margin indentation is used under the following conditions:

- when existing text in a window is flowed with the TF command
- when text is inserted in a window when the AUTOFLOW command is turned on
- when existing text in a window is split with the TS command

Comparisons

The left boundary can be set by both the INDENT and BOUNDS commands. However, when text is flowed, turning the INDENT command on always determines the left boundary, and overrides the left boundary set by the BOUNDS command.

Examples:

Example 1

This example shows four lines of text. The TF command is entered in the number field of the first line. The first line of the paragraph is indented. The INDENT command is set to ON, and the default boundaries are 1 and 50:

```
  tf 01       The purpose of Monday's meeting is to review
              the documentation plan and gather your responses. Please
              send a representative
              if you are unable to attend.
```

Example 2

The following example shows the result of pressing Enter to issue the TF command. The indention is used for all of the lines and the right boundary is 50:

```
  tf 01       The purpose of Monday's meeting is to review
              the documentation plan and gather your responses. Please
              send a representative
              if you are unable to attend.
```

- “TS Command” on page 577
JC Command
Centers a designated line of text.

Syntax

\texttt{JC <n>}

Without Arguments

The JC command centers the designated line of text that contains the line command based on the left and right boundary settings.

Optional Argument

\texttt{n} specifies the column position on which to center the designated line of text. Follow the \texttt{n} argument with a space.

Details

The JC command centers a designated line of text. Unless you specify a numeric argument, centering is based on the current boundary settings set by the BOUNDS command. A numeric argument overrides these boundary settings.

Comparisons

Like the JL, JJL, JR, and JJR commands, the JC and JJC commands align text.

See Also

\textbf{Commands:}

\begin{itemize}
  \item "BOUNDS Command" on page 549
  \item "JJC Command" on page 562

  \item "JJR Command" on page 564
\end{itemize}

JJC Command
Centers each line of text independently in a designated block of text.
Category: Text Editing, Line Command

Syntax

JJC

\textit{block-of-text}

JJC

Details

The JJC command centers a designated block of text. Each line in the block is centered independently. Centering is based on the current boundary settings set by the BOUNDS command.

Comparisons

Like the JL, JJL, JR, and JJR commands, the JC and JJC commands align text.

\section*{JJL Command}

Left-aligns a designated block of text.

Category: Text Editing, Line Command

Syntax

\texttt{JJL <n>}

\textit{block-of-text}

\texttt{JJL <n>}

Without Arguments

The JJL command left-aligns a designated block of text. Alignment is based on the left and right boundary settings.
Optional Arguments

\( n \)
 specifies the column position on which to left-align the designated block of text. By default, the \( n \) argument is the left boundary setting. Follow the \( n \) argument with a space. You can specify the numeric argument in the beginning or ending line of the block command or in both. If it is specified in both, then the first numeric argument is used.

block-of-text
 specifies a block of text to be left aligned.

Details
The JL command left-aligns a designated block of text. Unless you specify a numeric argument, left-alignment is based on the current boundary settings set by the BOUNDS command. A numeric argument overrides these boundary settings.

Comparisons
Like the JC, JJC, JR, and JJR commands, the JL and J JL commands align text.

---

### JJR Command

Right-aligns a designated block of text.

**Category:** Text Editing, Line Command

**Syntax**

\[
\text{JJR} \ <n> \ \text{block-of-text} \ \text{JJR} <n>
\]
Without Arguments

The JJR command right-aligns a designated block of text. Alignment is based on the left and right boundary settings.

Optional Arguments

\[ n \]

specifies the column position on which to right-align the designated block of text. By default, the \( n \) argument is the right boundary setting. Follow the \( n \) argument with a space. You can specify the numeric argument in the beginning or ending line of the block command or in both. If it is specified in both, then the first numeric argument is used.

\[ \text{block-of-text} \]

specifies a block of text to be right aligned.

Details

The JJR command right-aligns a designated block of text. Unless you specify a numeric argument, right-alignment is based on the current boundary settings set by the BOUNDS command. A numeric argument overrides these boundary settings.

Comparisons

Like the JC, JJC, JL, and JJL commands, the JR and JJR commands align text.

JL Command

Left-aligns a designated line of text.

Category: Text Editing, Line Command

Syntax

\[ \text{JL } <n> \]
Without Arguments

The JL command left-aligns the designated line of text. Alignment is based on the left and right boundary settings.

Optional Argument

\( n \)

specifies the column position on which to left-align the designated line of text. By default, the \( n \) argument is the left boundary setting. Follow the \( n \) argument with a space.

Details

The JL command left-aligns a designated line of text. Unless you specify a numeric argument, left-alignment is based on the current boundary settings set by the BOUNDS command. A numeric argument overrides those boundary settings.

Comparisons

Like the JC, JJC, JR, and JJR commands, the JL and JJL commands align text.

- “JR Command” on page 566

### JR Command

Right-aligns a designated line of text.

**Category:** Text Editing, Line Command

**Syntax**

\[ \text{JR} \ <n> \]

Without Arguments

The JR command right-aligns the designated line of text. Alignment is based on the left and right boundary settings.
Optional Argument

\( n \)

- specifies the column position on which to right-align the designated line of text. By default, the \( n \) argument is the right boundary setting. Follow the \( n \) argument with a space.

Details

The JR command right-aligns a designated line of text. Unless you specify a numeric argument, right-alignment is based on the current boundary settings set by the BOUNDS command. A numeric argument overrides these boundary settings.

Comparisons

Like the JC, JJC, JL, and JJL commands, the JR and JJR commands align text.

---

**KEYS Command**

Enables you to assign function keys to tasks.

**Category:** Text Editing, Command-Line Command

**Syntax**

KEYS

**Comparisons**

The KEYS command enables you to access the KEYS window so that you can assign function keys to tasks.
M Command

Moves one line of text.

Category: Text Editing, Line Command

Syntax

M <n>

intervening-text

A | B

Required Arguments

A marks the target position of the line of text to be moved; in this case, after the line where the A argument is entered. You can place the A argument either before or after the line to be moved.

B marks the target position of the line of text to be moved; in this case, before the line where the B argument is entered. You can place the B argument either before or after the line to be moved.

Optional Argument

n specifies the number of lines of text to move. Follow the n argument with a space. Without the n argument, only the line of text that contains the line command is moved.

Details

The M command moves a designated line of text to a new position anywhere in a window.

See Also

Commands:

- "MM Command" on page 569

MASK Command

Defines the contents of one or more new lines.

Category: Text Editing, Line Command
Syntax

MASK

Without Arguments

The MASK command defines, displays, and enables you to edit the contents of one or more new lines that are created by the I command.

Details

The MASK command defines, displays, and enables you to edit the contents of one or more new lines that are created by the I command. The default setting for the new lines are blank lines. To display or edit a new line, type MASK in the number field of the line, and then press Enter. The line with the contents defined by the MASK command is inserted. You can then edit the line. A line with the contents defined by the MASK command is inserted each time you issue the I command.

The contents defined by the MASK command remain in effect for that window throughout your current SAS session unless you change them. To change the contents, type over the text. If you want to return to the default (a blank line), do one of the following tasks:

- blank any characters in the text field of the MASK line.
- issue the CLEAR command with MASK as an argument:

```
clear mask
```

The contents of the MASK line are cleared, and a note appears in the log indicating that the MASK line has been cleared.

You can use the RESET command or the D command to not display the contents of the MASK command. The MASK command remains in effect even when it is not displayed. For example, the MASK command remains in effect under the following conditions:

- when you scroll past the MASK line and it is not displayed
- when you issue the D or RESET command without blanking any characters in the text of the MASK line

In some windows, such as the Program Editor window, you can use the WSAVE command to permanently save the contents of the MASK command.

See Also

**Commands:**

- “D Command” on page 556
- “RESET Command” on page 572

---

**MM Command**

Moves a block of text.

Category: Text Editing, Line Command
Syntax

MM

*block-of-text*

MM

*intervening-text*

A | B

Required Arguments

A marks the target position of the lines of text to be moved; in this case, after the line where the A argument is entered. You can place the A argument either before or after the lines to be moved.

B marks the target position of the lines of text to be moved; in this case, before the line where the B argument is entered. You can place the B argument either before or after the lines to be moved.

See Also

Commands:

- "M Command" on page 568

---

**NUMBERS Command**

Adds or removes line numbers.

Category: Text Editing, Command-Line Command

Syntax

**NUMBERS** \(<\text{ON} | \text{OFF}>\)

Without Arguments

The NUMBERS command is toggled on or off. The first time you issue the NUMBERS command, it reverses the current setting. If the current setting is ON, then issuing the NUMBERS command changes the setting to OFF. If the current setting is OFF, then issuing the NUMBERS command changes the setting to ON.

Optional Arguments

**ON**

turns on the NUMBERS command in the window, so that the lines in the Program Editor are numbered.
OFF

turns off the NUMBERS command in the window, so that the lines in the Program Editor are not numbered.

Details

The NUMBERS command adds or removes line numbers for data lines in windows that allow text editing. When you issue the NUMBERS command to remove line numbers, the line numbers disappear and all text shifts left. When you issue the NUMBERS command to add line numbers, the numbers are displayed on the left, and all of the text shifts right. The alias for the NUMBERS command is NUMS.

R Command

Repeats a designated line.

Category: Text Editing, Line Command

Syntax

\texttt{R \langle n \rangle}

Without Arguments

The R command repeats a designated line one time.

Optional Argument

\texttt{n}

specifies the number of times to repeat the designated line. Follow the \texttt{n} argument with a space.

Details

The R command repeats a designated line immediately after the designated line. The default is one time.

Comparisons

The R and RR commands repeat the line or block of lines immediately after the line with the R or RR command. The C and CC commands enable you to copy one or more lines anywhere in a window.

See Also

Commands:

- “C Command” on page 550
- “CC Command” on page 552
- “RR Command” on page 572
RESET Command

Removes any pending line commands.

Category: Text Editing, Command-Line Command

Syntax

RESET

Without Arguments

The RESET command removes any pending line commands.

Details

The RESET command removes any pending line commands. It also removes any MASK lines that were created when the MASK command was issued. The display of the MASK line, not the setting of the MASK command, is removed. If you do not want to complete a command on a block of lines (such as the MM or CC command), you can issue the RESET command to remove the pending command.

Comparisons

The RESET command has the same result as the D command. The RESET command also removes the display of MASK lines from the MASK command.

See Also

Commands:

- “D Command” on page 556

RR Command

Repeats a block of lines.

Category: Text Editing, Line Command

Syntax

RR <n>

block of text

RR <n>
Without Arguments
The RR command repeats the block of lines one time.

Optional Argument

\( n \)
specifies the number of times to repeat the designated block of lines. Follow the \( n \) argument with a space. You can specify the numeric argument in the beginning or ending line of the block command or in both. If it is specified in both, the first numeric argument is used.

Details
The RR command repeats a designated block of lines immediately after the designated block of lines. The default is one time.

Comparisons
The R and RR commands repeat the line or block of lines immediately after the line with the R or RR command. The C and CC commands enable you to copy one or more lines anywhere in a window.

Commands:
- “C Command” on page 550
- “CC Command” on page 552
- “R Command” on page 571

SPELL Command
Checks spelling and flags unrecognized words.
Category: Text Editing, Command-Line Command

Syntax

SPELL <ALL <SUGGEST>>
SPELL <NEXT | PREV | SUGGEST>
SPELL <REMEMBER <dictionary-name>>

Without Arguments
The SPELL command checks the first word if the cursor is positioned on the command line. Otherwise, the SPELL command checks the word on which the cursor is positioned. Assign a function key to the SPELL command by using the KEYS command. Use the function key to check the spelling of the word on which
the cursor is positioned. If the word is recognized, the message “OK” appears. Otherwise, a message appears that indicates the word is unrecognized.

Optional Arguments

ALL
checks the spelling of all words. If all words are recognized, a message indicates that no unrecognized words have been found.

If a word is unrecognized, the SPELL: Unrecognized Words window appears, listing the unrecognized words and their corresponding line numbers. The window initially displays a blank field for the dictionary that you want to specify. Enter a new dictionary name, or the name of an existing dictionary. Select Tools \Rightarrow Remember to add the unrecognized words to the dictionary.

Tip Specify the SPELL ALL SUGGEST command to display the SPELL: Suggestions window for each unrecognized word that is found.

SUGGEST
invokes the SPELL: Suggestions window, which displays the last unrecognized word and its line number, and suggestions for changing the unrecognized word. In this window, you can select Tools \Rightarrow Remember to add the unrecognized word to a dictionary. The window then closes, you are returned to the previous window, and a message indicates that the word is now recognized.

You can change the unrecognized word by positioning your cursor on a suggestion, and then pressing Enter. The suggested word is highlighted. Select Tools \Rightarrow Replace. When you return to the Program Editor window, you will see that the unrecognized word has been changed. If you want to replace all occurrences of the recognized word, first, position the cursor on the phrase ALL OCCURRENCES, and then press Enter. The phrase ALL OCCURRENCES is highlighted. When you return to the Program Editor window, you can see that all occurrences of the unrecognized word have been changed.

Alias ?

NEXT
finds the next unrecognized word, based on the current cursor position. If all words from the current cursor position to the end of the file are recognized, a message indicates that the end of the file was reached. Otherwise, a message indicates that a word is unrecognized, and the cursor is positioned on the unrecognized word.

PREV
finds the previous unrecognized word, based on the current cursor position. If all words from the current cursor position to the beginning of the file are recognized, a message indicates that the beginning of the file was reached. Otherwise, a message indicates that a word is unrecognized, and the cursor is positioned on the unrecognized word.

REMEMBER dictionary-name
adds the last unrecognized word to an auxiliary dictionary, where dictionary-name is the name of an auxiliary dictionary. A message indicates that the word has been added to an auxiliary dictionary. If you are using only one auxiliary dictionary, you can omit dictionary-name. If no auxiliary dictionary is specified, and dictionary-name is omitted, the unrecognized word is saved in a temporary dictionary in the current SAS session only.
You can highlight a word from the SPELL: Unrecognized Words window or from the SPELL: Suggestions window, and then select Tools ➔ Remember. The word that you added is now recognized.

Details

The SPELL command checks spelling and flags unrecognized words. You can use the SPELL command to do the following tasks:

- See suggestions for unrecognized words.
- Add unrecognized words to an auxiliary dictionary.
- Replace unrecognized words with suggestions.

The SPELL command checks words with a default dictionary. However, you can specify one or more auxiliary dictionaries to use in addition to the default dictionary.

Any dictionary that you create is stored in your Sasuser.Profile catalog. If you update a dictionary using the SPELL REMEMBER command, updates are saved to a temporary dictionary in the current SAS session. The temporary dictionary is created if you do not specify a dictionary name. If you specify a dictionary from the Sashelp.Base catalog, updates are saved in that dictionary.

Comparisons

The SPELL command checks spelling and flags unrecognized words, and the DICT command includes or creates an auxiliary dictionary. The SPELL command can also create and update auxiliary dictionaries. Use the SPELL command to create a permanent auxiliary dictionary. The word list that is used by the SPELL command acts as a record of the words that are contained in the auxiliary dictionary.

Commands:

- "DICT Command" on page 557

TC Command

Connects two lines of text.

Category: Text Editing, Line Command

Syntax

TC

Without Arguments

The TC command connects two lines of text.
Details

The TC command connects two lines of text. To connect two lines of text, type TC in the number field of a line, and press Enter or Return. The text from the second line moves to the first line. No space appears between text on the first line and text on the second line. To create a space between the last word of the first line and the first word of the second line, start the text of the second line in the second column.

The command does not truncate text.

Comparisons

The TC command is the opposite of the TS command, which splits text at the cursor. It is similar to the TF command, except that it breaks text at boundaries instead of flowing text in a paragraph by removing trailing blanks.

See Also

Commands:
- “TF Command” on page 576
- “TS Command” on page 577

TF Command

Flows text to a blank line or to the end of the text.

Category: Text Editing, Line Command

Syntax

TF <A> <n>

Without Arguments

The TF command flows text to the first blank line, or to the end of the text, whichever comes first, based on left and right boundary settings.

Optional Arguments

A

flows text in a paragraph to the end of the text by removing trailing blanks, continuing over, but not deleting, blank lines. This argument, like the numeric argument, must be specified on the same line as the TF command. You cannot have any characters between the TF command and the A argument.

n

specifies a right boundary to temporarily override the right boundary set by the BOUNDS command. Follow the n argument with a space.
TS Command

Splits text at the cursor.

Category: Text Editing, Line Command

Syntax

\textbf{TS} <\textit{n}>

Without Arguments

The TS command splits the line of text at the cursor, and moves the remaining text to a new line.

Optional Argument

\textit{n}

specifies how many lines down to move the remaining text. The default is one line. Follow the \textit{n} argument with a space.

Details

The TS command splits the line of text at the cursor, and moves the remaining text to a new line starting at the left margin. If you specify a numeric argument, the TS command moves the text down the number of lines specified. With the AUTOFLOW command turned on, the TS command uses the left boundary that is specified by the BOUNDS command. If the INDENT command is turned on, the TS command uses the current indentation at the left margin. With the AUTOFLOW command turned off, the left boundary and the current indentation at the left margin are reset.

This example shows the effect of splitting two statements in a SAS program and placing each statement on a separate line. This example shows the text after you type the TS command on line 0001 and position the cursor after the first statement, and before you press Enter or Return:

\begin{verbatim}
ts 01 proc print data=temp; run;
\end{verbatim}

When you press Enter or Return, the following result is displayed:

\begin{verbatim}
00001 proc print data=temp;
00002 run;
\end{verbatim}

Comparisons

The TS command, with its default numeric argument of 1, is the same as entering a carriage return or pressing Enter or Return with the AUTOSPLIT command turned on. The TS command contrasts with the TC command and the TF command. The TC command connects two lines of text. The TF command flows text to a blank line or to the end of the text. With the AUTOFLOW command turned on, the TS command is affected by both the BOUNDS and INDENT commands.

---

**UNDO Command**

Cancels an action.

**Syntax**

**UNDO**

**Without Arguments**

The UNDO command cancels the most recent action in an active window that allows text editing.

**Details**

The UNDO command cancels the most recent action in an active window that allows text editing. The action must be a command that enters or modifies text. If you want to undo more than one action, you must continue to issue the UNDO command. Actions are undone one at a time, starting with the most recent action and moving backward.

---

**Note:** The UNDO command cannot undo the SUBMIT command. It cannot reverse the effects of submitted SAS statements.

---

**Comparisons**

Although you cannot undo the SUBMIT command, you can use the RECALL command to recall submitted statements back to the Program Editor window.

If you use the CC command to copy and paste a block of text, and then you issue the UNDO command, the block of text that you copied and pasted is deleted. If you use the DD command to delete a block of text, and then you issue the UNDO command, the block of text that you deleted is restored.

---

**< Command**

Shifts to the left a designated line of text.
Syntax

< <n>

Without Arguments
The < command shifts a designated line of text one space to the left.

Optional Argument

n  specifies the number of spaces that the designated line of text shifts. Follow the n argument with a space.

Details
The < command shifts a designated line of text one or more spaces to the left. The line shifts the number of spaces that you specify with the n argument, or the line shifts at the left window border, whichever is less. This text-shift command does not lose characters when shifting.

Comparisons
The > and >> commands shift text in the opposite direction from the < and << commands. The ), ), , and (() commands are similar text-shift commands, which, depending on the extent of the shift, can lose characters.

See Also

Commands:
- "<< Command" on page 579

<< Command

Shifts to the left a designated block of text.

Syntax

<< <n>

block-of-text

<< <n>
Without Arguments
The << command shifts a designated block of lines of text one space to the left.

Optional Argument
n
specifies the number of spaces that the designated block of lines of text shifts. Follow the n argument with a space. You can specify the numeric argument in the beginning or ending line of the block command, or in both. If it is specified in both, the first numeric argument is used.

Details
The << command shifts a designated block of lines of text one or more spaces to the left. The block of lines of text shifts the number of spaces that you specify with the n argument, or the block shifts at the left window border, whichever is less. This text-shift command does not lose characters when shifting.

Comparisons
The > and >> commands shift text in the opposite direction from the < and << commands. The ), ), (, and (( commands are similar text-shift commands, which, depending on the extent of the shift, can lose characters.

> Command
Shifts to the right a designated line of text.
Category: Text Editing, Line Command

Syntax
> <n>

Without Arguments
The > command shifts a designated line of text one space to the right.

Optional Argument
n
specifies the number of spaces that the designated line of text shifts. Follow the n argument with a space.

Details
The > command shifts a designated line of text one or more spaces to the right. The line shifts the number of spaces that you specify with the n argument, or the line shifts at the left window border, whichever is less. This text-shift command does not lose characters when shifting.
Comparisons

The < and << commands shift text in the opposite direction from the > and >> commands. The ), ), (, and (( commands are similar text-shift commands, which, depending on the extent of the shift, can lose characters.

See Also

Commands:

- ">> Command" on page 581

>> Command

Shifts to the right a designated block of text.

Category: Text Editing, Line Command

Syntax

```
>> <n>
block of text
>> <n>
```

Without Arguments

The >> command shifts a designated block of lines of text one space to the right.

Optional Argument

$n$

Specifies the number of spaces that the designated block of lines of text shifts. Follow the $n$ argument with a space. You can specify the numeric argument in the beginning or ending line of the block command, or in both. If it is specified in both, the first numeric argument is used.

Details

The >> command shifts a designated block of lines of text one or more spaces to the right. The block of lines of text shifts the number of spaces that you specify with the $n$ argument, or the block shifts at the left window border, whichever is less. This text-shift command does not lose characters when shifting.

Comparisons

The < and << commands shift text in the opposite direction from the > and >> commands. The ), ), (, and (( commands are similar text-shift commands, which, depending on the extent of the shift, can lose characters.
( Command

Shifts to the left one designated line of text.
Category: Text Editing, Line Command

Syntax

( <n>

Without Arguments

The ( command shifts a designated line of text one space to the left.

Optional Argument

n
specifies the number of spaces that the designated line of text shifts. The default is one space. Follow the n argument with a space.

Details

The ( command shifts a designated line of text one or more spaces to the left. If the shift extends past the beginning of the current line, characters are lost.

Comparisons

The ) and )) commands shift text in the opposite direction from the ( and (( commands. The <, <<, >, and >> commands are similar text-shift commands, but they do not lose characters when shifting.

See Also

Commands:

- “> Command” on page 580

(( Command

Shifts to the left a designated block of lines of text.
Category: Text Editing, Line Command
Syntax

\[ (( \langle n \rangle ) \text{ block-of-text} \langle n \rangle ]

Without Arguments

The \((\) command shifts a designated block of lines of text one space to the left.

Optional Argument

\[ \langle n \rangle \]

specifies the number of spaces that the designated block of lines of text shifts. The default is one space. Follow the \(n\) argument with a space. You can specify the numeric argument in the beginning or ending line of the block command, or in both. If it is specified in both, the first numeric argument is used.

Details

The \((\) command shifts a designated block of lines of text one or more spaces to the left. If the shift extends past the beginning of the current line, characters are lost.

Comparisons

The \(\) and \\)) commands shift text in the opposite direction from the \(\) and \((\) commands. The \(<, \ll, >, \) and \(\gg\) commands are similar text-shift commands, but they do not lose characters when shifting.

About EBCDIC and ASCII Data

Overview of EBCDIC and ASCII Data Representation

Extended Binary Coded Decimal Interchange Code (EBCDIC) is an 8-bit character encoding method for IBM mainframe machines. American Standard Code for Information Interchange (ASCII) is a 7-bit character encoding method for most other machines, including Windows, UNIX, and Macintosh machines.

Hexadecimal characters are used to represent one byte or eight bits of data. In a binary system, each bit can have the value 0 or 1. An aggregation of four bits can therefore take on 16 ($2^4$) possible values. This means that two hexadecimal characters can be used to represent one byte of data. In the EBCDIC and ASCII encoding methods, each character is represented by two hexadecimal characters. (This pertains primarily to Western language, single-byte encoding methods. There
are other encoding methods that store a single character in two bytes of storage, such as encoding methods that are used for Japanese or Korean data.)

Each encoding method represents the same data differently, as shown in the following examples:

- On an EBCDIC system, the digit 4 is represented by the hexadecimal value ‘F4’x. On an ASCII system, the digit 4 is represented by the hexadecimal value ‘34’x.

- On an EBCDIC system, the hexadecimal value ‘50’x represents the symbol &. On an ASCII system, the same hexadecimal value represents the letter P.

When SAS reads a file, it expects the data in the file to be in the encoding that matches the ENCODING= option for the SAS session. For example, on a Windows machine, the default encoding for a single-byte SAS session with a US English locale is LATIN1. SAS expects the data in a file on that Windows machine to use a LATIN1 encoding. However, if a file originates on an EBCDIC machine and it is stored on a Windows machine, then SAS would misinterpret the data from this file if no other encoding information is provided. For this reason, specific steps must be performed to convert data that originates on an EBCDIC system before it can be used on an ASCII system (for example, the Windows machine). Here are the two main methods to make EBCDIC data available on an ASCII system:

- On the ASCII system, read the data directly from the EBCDIC system.
- Use an FTP program to move the data, with or without any conversion of the data.

---

**EBCDIC File Structures**

When you decide how to move data from an EBCDIC system to an ASCII system, consider the structure of the EBCDIC source file. On EBCDIC systems, you might have files with fixed-length records or files with variable-length records. Either type of file contains a header with information about the file. The header includes a Record Format attribute that indicates whether the records are fixed length or variable length. The header for a file with fixed-length records includes a Logical Record Length attribute that indicates the length of each record in bytes.

In SAS, the Record Format attribute corresponds to the RECFM= option in a FILENAME statement. To access a file with fixed-length records, specify RECFM=F. To access a file with variable-length records, specify RECFM=V. Similarly, the Logical Record Length attribute corresponds to the LRECL= option.

The Logical Record Length attribute in the header for a file with variable-length records indicates the maximum record length. Each record in a file with variable-length records begins with a record descriptor word (RDW). The RDW is a 4-byte binary integer field. The first two bytes of the RDW indicate the length of the current record. The last two bytes of the RDW contain information that is used by the operating system. The length of the record includes the four bytes of the RDW at the beginning of the record. Because the length of each record is specified in an EBCDIC file (either in the header or in the RDW), there are no end-of-record indicators in EBCDIC files.

A file with variable-length records also contains block descriptor words (BDWs). Like the RDW, the BDW is a 4-byte, binary integer field. The first two bytes indicate the block size, and the last two bytes are used by the operating system. Each block can contain multiple records. If the block size is not specified when the file is created,
the default block size is the logical record length plus 4. Otherwise, the size of a block is the number of bytes that are contained in the block. This value is the sum of the record lengths in the block (obtained from the RDWs) plus 4 (the length of the BDW).

ASCII File Structure

On ASCII systems, a file does not contain a header with information about the file, such as record format or lengths. The RECFM attribute for ASCII files is variable (RECFM=V), and the record length (LRECL) is unlimited. Instead of defining record lengths like EBCDIC files do, ASCII files use end-of-record indicators to flag the end of a record. On a Windows machine, the end-of-record indicators are the carriage return (CR) and line feed (LF) characters. On a UNIX machine, an LF indicates the end of a record. On a Macintosh machine, a CR indicates the end of a record. Other types of machines use different combinations of characters to identify the end of record. For all ASCII machines, the hexadecimal value for CR is '0D'x, and the hexadecimal value for LF is '0A'x.

When SAS reads a file from disk on an ASCII machine, default values for some file attributes must be used because these attributes are not defined. The default RECFM value is V (variable-length record), and the default LRECL value is 32767. This means that SAS scans the input from an ASCII file, parses the data into variable values based on the INPUT statement, and looks for an end-of-record indicator. If the end of a record is not found within the specified number of characters (based on LRECL), then SAS truncates the record and prints a message in the log. For example, suppose LRECL is set to 256, and there is a record that is 300 characters. SAS reads the first 256 characters based on the INPUT statement, and then discards the last 44 characters. A message in the log states that "One or more lines have been truncated." You can override the current LRECL value using the LRECL= option in the INFILE statement.

Numeric Values

When stored as character data, the decimal digits 0 through 9 each occupy one byte of storage. One 8-bit byte includes two 4-bit nibbles. Each nibble can have 16 (2⁴) possible values. The first nibble is the high-order nibble, and the second is the low-order nibble. In EBCDIC and ASCII systems, the high-order nibble has a standard value. Decimal digits are represented in EBCDIC with a high-order nibble of F. Decimal digits are represented in ASCII with a high-order nibble of 3. This means that in an EBCDIC system, the digits 0 through 9 are represented by the hexadecimal values 'F0'x through 'F9'x. In an ASCII system, the digits 0 through 9 are represented by the hexadecimal values '30'x through '39'x. This encoding method treats decimal digits as characters.

As an alternative to storing decimal digits as characters, there are other encoding methods that can be used on an EBCDIC system. For example, a packed-decimal encoding method represents two decimal digits in one byte of storage. A zoned-decimal encoding method represents one decimal digit in one byte of storage, and the sign of the entire value is included within one byte of storage. (The byte that stores the decimal digit and the sign of the entire value can be either the first byte or the last byte, depending on the type of machine.)
You must know the numeric encoding that is used on the source EBCDIC system so that the source data is interpreted correctly on the ASCII system. For SAS, this means that you must specify the correct informats to use for numeric data.

Moving Data from EBCDIC to ASCII Systems

Overview of Accessing EBCDIC Data on ASCII Systems

There are several ways to access EBCDIC data on an ASCII system. For example, some ASCII machines have peripheral devices that can read 3480 or 3490 cartridge tapes that are created on an EBCDIC system. These devices can read the data directly from a tape into an application on an ASCII machine. Alternatively, these devices can copy data from a tape and store it on the ASCII machine’s hard drive.

A more common method of moving and converting data is to use an FTP program to transfer the data. By default, most FTP programs convert EBCDIC data into ASCII when transferring data. If the source data contains only character data (including digits that are encoded as characters), this is the recommended method. During the conversion process, the FTP program creates the appropriate end-of-record indicators for the ASCII system. After conversion, you can use an INFILE statement to access the newly created file on the ASCII system. Use an INPUT statement to specify the correct informat values to use when reading the data in the file.

Note: Even when all of the EBCDIC source data is encoded as character data, there might be some characters that are not interpreted correctly during conversion. The correct interpretation of these characters depends on the encoding method that is used on the EBCDIC machine. As a best practice, verify that your data was converted correctly by viewing the data that SAS reads from a converted file.

When an EBCDIC file contains numeric data that is not encoded as character data, such as when a packed-decimal or zoned-decimal encoding method is used, the default FTP conversion does not work correctly. Some numeric data can resemble standard character data. In this case, FTP conversion incorrectly assigns ASCII characters to EBCDIC numeric data. For more information, see “Example of Incorrect Conversion of Packed-Decimal Numeric Data”.

Note: There is no way to correctly convert packed-decimal encoded data from EBCDIC into ASCII. Other methods to convert the data must be used if a packed-decimal, zoned-decimal, or other numeric encoding method is used on the EBCDIC system. For more information, see “Convert EBCDIC Files with Variable-Length Records” on page 592.

In some instances, a byte of EBCDIC data might be interpreted in ASCII as an end-of-line flag or end-of-file flag. If SAS is reading a file with variable-length records when one of these hexadecimal values is encountered, then you might observe unintended results. Depending on the expected data values based on specified informats, you might observe anything from invalid data errors to unexpected termination of the DATA step.
Example of Incorrect Conversion of Packed-Decimal Numeric Data

This example demonstrates the problems that can result when you convert packed-decimal numeric data as if it were encoded as character data. Suppose an EBCDIC data file contains the numeric value 505, stored as a packed-decimal value ('505C'x). If you looked at the file with an EBCDIC file browser or editor, you would see the characters &*. This is because '50'C'x corresponds to & and '5C'x corresponds to *. The FTP program interprets the & character and converts it to the ASCII value '26'x. The FTP program converts the * character to the ASCII value '2A'x, and the resulting converted value is '262A'x. The correct packed-decimal value in ASCII should be '000505'x. Because the input data does not conform to the expected packed-decimal informat, SAS prints an error to the log that states that the data is invalid. Each time invalid data is encountered, SAS writes an error to the log, and prints the contents of the input buffer and the corresponding DATA step variables.

Convert EBCDIC Files with Fixed-Length Records

FTP the File in Binary

When you convert an EBCDIC file with fixed-length records, use FTP to transfer the file in binary. Then, with a FILENAME or INFILE statement, specify RECFM=F, and assign the same value to LRECL that the file has in the EBCDIC system. Use the formatted input style with the following informats:
- $EBCDICw.$ for character input data
- S370Fxxxw.d for numeric input data

Note: There are many S370Fxxxw.d informats. Select those informats that match the type of data that you have. For more information, see SAS Formats and Informats: Reference for SAS 9.3 and higher, or see SAS Language Reference: Dictionary for earlier versions of SAS.

Because you are transferring the source file in binary, there is no processing to add end-of-record indicators. For this reason, you must specify the exact number of bytes that are specified for the source file in the EBCDIC system. If there are bytes in the source file that would be interpreted as end-of-record indicators or end-of-file indicators in an ASCII context, SAS treats those bytes simply as data.

Example: Convert an EBCDIC File with Fixed-Length Records into an ASCII File

The following code reads a file, fixed.txt, that was previously transferred via FTP in binary from an EBCDIC system to an ASCII system. The source file has fixed-length records that are 60 bytes long. Based on the informat in this example, the last three bytes in each record contain numeric data that was stored using the packed-decimal encoding method.

```sas
filename test1 'c:\fixed.txt' recfm=f lrecl=60;
data one;
infile test1;
input @1  name  $ebcdic20.
    @21 addr  $ebcdic20.
    @41 city  $ebcdic15.
    @56 state $ebcdic2.
    @58 zip   $s370fpd3.;
run;
```

Convert EBCDIC Files with Variable-Length Records

Overview of Converting EBCDIC Files with Variable-Length Records

When you convert an EBCDIC file with variable-length records, you can use an FTP program. The FTP program removes BDWs and RDWs and adds end-of-record indicators that are expected by the ASCII system. The data in the file is converted from EBCDIC to ASCII. If all of the data in the EBCDIC file is encoded as characters, then this process typically works correctly.

Note: Even when all of the EBCDIC source data is encoded as character data, there might be some characters that are not interpreted correctly during conversion. The correct interpretation of these characters depends on the encoding method that is used on the EBCDIC machine. As a best practice, verify that your data was converted correctly by viewing the data that SAS reads from a converted file.
When an EBCDIC file contains numeric data that is not encoded as character data, such as when a packed-decimal or zoned-decimal encoding method is used, the default FTP conversion does not work correctly. For more information, see "Overview of Accessing EBCDIC Data on ASCII Systems" on page 590. To prevent misinterpretation of data during conversion, transfer the file in binary via FTP without converting the data to an ASCII encoding. When the data is transferred in binary and is not converted, be aware that the BDW and RDW information is removed automatically. This removes information that SAS needs to read the data successfully.

Read Files Directly from the EBCDIC System

If you have direct access between the ASCII machine and the EBCDIC machine, then the best practice is to read the file directly. Direct access is enabled via a peripheral device on the ASCII machine that can read an EBCDIC tape. You can access the file via the FTP access method in a FILENAME statement. There are several advantages to this method of accessing EBCDIC data:

- file preprocessing is not required
- copying the source file is not required
- FTP access method works for fixed-length and variable-length records
- DATA step processing works as expected

The main disadvantage is that this method requires more time for processing because you are accessing the data remotely.

This method of accessing EBCDIC data applies if you have a 3480 or 3490 cartridge tape reader attached to your ASCII machine. In this case, you do not need to preprocess the file on an EBCDIC machine. You can read it directly from the tape by setting RECFM=S370VB and using the $EBCDICw. and S370Fxxxw.d informats.

In a FILENAME statement, specify the FTP access method and the source filename, and provide values for the HOST=, USER=, and PASS= options. The HOST= option specifies the name of the EBCDIC machine, USER= specifies the user account that you use to log on, and PASS= specifies the password that you use to log on. The FTP access method uses an FTP program on the ASCII machine to open a connection between the ASCII machine and the EBCDIC machine. The SAS system connects to and logs on to the mainframe machine with the specified user account and password. The FTP program transfers the file.

Note: If you specify the PASS= option, the password is saved as text in your SAS program. The password is not visible in the SAS log. As an alternative to the PASS= option, you can specify the PROMPT option and provide a password at the prompt when you execute the SAS program.

For EBCDIC files with variable-length records, you must also specify the S370V and RCMD= options. The S370V option indicates that the records in the source file have variable lengths. For the RCMD= option, specify RCMD="SITE RDW" to indicate that the FTP process should keep the RDW information during the file transfer.

If you experience connection problems to the EBCDIC machine, you can add the DEBUG option to see the informational messages that are sent to and from the FTP server.
Example: Read an EBCDIC Source File Directly with the FTP Access Method

This example shows how to read an EBCDIC file with variable-length records directly from an EBCDIC machine using the FTP access method. The user is prompted for her MVS logon password. The ZIP code is entered as a 5-digit EBCDIC number, represented by one digit per byte. The comments section is varying in length up to 200 characters. After the data is read, it is printed to verify the contents of the data set.

```plaintext
filename test1 ftp '"SASEBCDIC.VB.TEST1'" host='MVS' user='SASEBCDIC' PROMPT
   s370v rcmd='site rdw';
data one;
infile test1;
   input @1  name     $ebcdic20.
     @21 addr     $ebcdic20.
     @41 city     $ebcdic10.
     @51 state    $ebcdic2.
     @54 zip      s370ff5.
     @60 comments :$ebcdic200.;
runc;
   proc print;
runc;
```

Reformat an EBCDIC File with Variable-Length Records with IEBGENER

Suppose that you do not have direct access between the ASCII machine and the EBCDIC machine. That is, you do not have a peripheral device that reads EBCDIC data on the ASCII machine. In this situation, you can convert the data by reformattting the file on the mainframe machine. By changing the format of the file, you prevent the FTP program from removing the RDW information that SAS requires to read the data correctly. After you reformat the file, you can transfer the file in binary to the ASCII machine.

To reformat the source file, use the IEBGENER program on the EBCDIC machine. Use this program to make an exact copy of the file with altered header information. Specifically, use IEBGENER to change the RECFM value from V (variable-length records in blocks) to U (undefined record length and unblocked). After making this change, the FTP program no longer removes the RDW information during the file transfer.

When you run the IEBGENER program, in addition to the required arguments, specify the following overrides:

```plaintext
   SYSUT1 DCB=(RECFM=U,BLKSIZE=32760)
   SYSUT2 DCB=(RECFM=U,BLKSIZE=32760) DISP=(NEW,CATLG)
```

Note: Do not use the original values of RECFM and BLKSIZE for SYSUT1.

Transfer the new version of the file in binary using an FTP program on the ASCII machine. In SAS, use a FILENAME or INFILE statement to read the transferred file. Set the options appropriately.
Set the RECFM= option to S370V if the record format for the original file was variable (RECFM=V). Set the RECFM= option to S370VB if the record format for the original file was variable and blocked (RECFM=VB). By specifying the RECFM= option as S370V or S370VB, you tell SAS to process the RDW information for each record and enter the correct number of bytes for each record.

Specify the same value for the LRECL= option that is in the original file. If you do not specify a value for the LRECL= option, SAS uses the default LRECL value (32767). Using the default value could cause SAS to truncate data records if they are longer than the default LRECL value.

Use the formatted input style with the informats that are described in “FTP the File in Binary” on page 591.

Example: Read a File with Modified Header Data

This example reads a file that was generated from an EBCDIC file with a header that was modified to change the file format. The modified file was transferred to an ASCII machine for SAS processing. For more information, see “Reformat an EBCDIC File with Variable-Length Records with IEBGENER” on page 594.

The TRUNCOVER option is included in the INFILE statement because the Comment variable can be up to 60 characters (but it is likely shorter). Without the TRUNCOVER option, the INPUT statement could attempt to read past the end of the record. Data from the next record would continue to be assigned to the Comment variable until the variable was full. The LRECL= option is not specified because the default value is sufficient to handle the longest record in the file. After the data is read, it is printed to output for verification.

```sas
filename test1 'c:\vbtest.xfr' recfm=s370vb;
data one;
infile test1 truncover;
input @1 name $ebcdic14.
   @15 addr $ebcdic18.
   @33 zip s370ff5.
   @38 comment $ebcdic60.;
run;

proc print;
run;
```

Read EBCDIC Data from Structured COBOL Files

About Structured COBOL Files

A structured COBOL file is generated using an OCCURS DEPENDING ON clause. This type of file has variable-length records. And, when the file is transferred via FTP in binary, there is no BDW or RDW information. Each record is divided into three parts: a record header (a fixed-length portion of the record), an index variable, and one or more data segments. The documentation for the file provides the length of the record header, the index variable, and a data segment. The record header is the same length for each record. It contains information that pertains to all of the data segments that follow. The index variable provides the number of data
segments for the current record. The remainder of the record contains the data segments.

Because of the structure of the records, SAS is able to read the data in these files. The length of a record is the sum of the header length, the index length, and the product of the index value and the size of each data segment. For each data segment, SAS reads the segment, and then writes a copy of the header and the current data segment to a new observation in a SAS data set.

When you read a structured COBOL file, specify RECFM=N in your FILENAME statement. This tells SAS that you are reading a stream of data that does not conform to a typical file structure. Any restrictions to record length are ignored when SAS reads a data stream because SAS does not attempt to buffer the input. SAS writes a statement to the SAS log to notify you that SAS reads a data stream as unbuffered when RECFM=N.

SAS reads an entire structured COBOL file as a single, long record. Therefore, if you need to skip some data or move past a space, you must use relative column pointers in your INPUT statement. Line holders are ignored because the contents of the file are treated as a single input record. The @column pointers do not work for these files.

**CAUTION**

Do not use @column pointers when you specify RECFM=N. Using @column pointers initiates an infinite loop in which SAS reads and writes the same data repeatedly until you halt the program or until no more disk space is available.

---

**Example: Read Data from a Structured COBOL File**

In this example, an EBCDIC file was transferred via FTP in binary without first processing the file using IEBGENER. The record header (fixed-length) portion of each record is 59 bytes in length and contains a combination of character and numeric data. The index variable is two bytes. There is another space (one byte) to separate the index variable from the remainder of the record. The data segment portion of the record consists of one or more repeats of 13 bytes in length. Each repeat contains a combination of character and numeric data.

```sas
filename test1 'c:\VB.TEST' recfm=n;
data one;
infile test1;
input name $ebcdic20. addr $ebcdic20. city $ebcdic10. st $ebcdic2. +1
   zip s370ff5. +1 idx s370ff2. +1;
do i = 1 to idx;
   input cars $ebcdic10. +1 years s370ff2. ;
   output;
   if i lt idx then input +1 ;
end;
run;
```
Moving Data from ASCII to EBCDIC Systems

Overview

There are several ways to transcode ASCII data to EBCDIC:

- Use FTP to write files (data) directly.
- Use the `dd` command.
- Use the `iconv` command.

Using FTP to Write Files Directly

Overview of Using FTP to Write Files Directly

FTP automatically performs the conversion when the type of file is specified as text (instead of binary). When you have direct access between the ASCII machine and EBCDIC machine, the best practice is to read the file directly. Direct access is enabled via a peripheral device on the ASCII machine that can read an EBCDIC tape. You can access the file via the FTP access method in a `FILENAME` statement. There are several advantages to this method of accessing EBCDIC data:

- No file preprocessing is required.
- You do not need to copy the source file.
- The FTP access method works for fixed-length and variable-length records.
- DATA step processing works as expected.

This method of accessing EBCDIC data applies if you have a 3480 or 3490 cartridge tape reader attached to your ASCII machine. In this case, you do not need to preprocess the file on an EBCDIC machine. You can read it directly from the tape by setting `RECFM=S370VB` and using the `$EBCDICw.` and `S370Fxxxw.d` informats.

In a `FILENAME` statement, specify the FTP access method and the source filename, and provide values for the `HOST=`, `USER=`, and `PASS=` options. The `HOST=` option specifies the name of the EBCDIC machine, `USER=` specifies the user account that you use to log on, and `PASS=` specifies the password that you use to log on. The FTP access method uses an FTP program on the ASCII machine to open a connection between the ASCII machine and the EBCDIC machine. The SAS system connects to and logs on to the mainframe machine with the specified user account and password. The FTP program transfers the file.

Example: Reading an ASCII File from SAS on z/OS

```sql
filename unixin '/net/bin/u/<user>/sample.txt' encoding=latin1;
```
Using the dd Command to Convert and Copy a File

About the dd Command

The dd command reads the InFile parameter or standard input, performs the specified conversion, and then copies the converted data to the OutFile parameter or standard output. The input block size and output block size can be specified to take advantage of raw physical I/O.

Use the cbs parameter value if you are specifying the block, unblock, ascii, ebcidic, or ibm conversion value. If an unblock or ascii value is specified, then the dd command performs a fixed-length to varying-length conversion. Otherwise, it performs a varying-length to fixed-length conversion. The cbs parameter value determines the fixed length.

**CAUTION**

If the specified cbs parameter value is smaller than the smallest input block, the converted block is truncated.

After it finishes, the dd command reports the number of whole and partial input and output blocks. For more information about the dd command, see the dd manual page on your system.

**dd Command Exit Status**

The dd command returns the following exit values:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The input file was copied successfully.</td>
</tr>
<tr>
<td>&gt;0</td>
<td>An error occurred.</td>
</tr>
</tbody>
</table>
Examples: dd Command Conversion

Here are two simple examples:

- To convert an ASCII text file to EBCDIC, enter the following:
  ```
  dd if=txt.ascii of=txt.ebcdic conv=ebcdic
  ```
  This command converts the `txt.ascii` file to EBCDIC representation and stores the EBCDIC version in the `txt.ebcdic` file.
  
  When you specify the `conv=ebcdic` parameter, the `dd` command converts the ASCII `^` (circumflex) character to an unused EBCDIC character (9A hexadecimal) and the ASCII `~` (tilde) character to the EBCDIC `^` character (NOT symbol).

- To use the `dd` command as a filter, enter the following:
  ```
  ls -l | dd conv=ucase
  ```
  This command displays a long listing of the current directory in uppercase.

The performance of the `dd` command and `cpio` command in the IBM 9348 Magnetic Tape Unit Model 12 can be improved by changing the default block size. To change the block size, use the `chdev` command as follows:

```
chdev -l Device_name -a block_size=32k
```

Using the `iconv` Command to Convert a Text File

About the `iconv` Command

Use the `iconv` command to convert the encoding of a text file. Use one of the following examples of syntax:

```
iconv -f FromCode -t ToCode FileName

iconv -l
```

For more information about the syntax and parameters for the `iconv` command, see the `iconv` manual page on your system.

`iconv` Command Exit Status

The `iconv` command returns the following exit values:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Input data was successfully converted.</td>
</tr>
</tbody>
</table>
The specified conversions are not supported, the input file cannot be opened or read, or there is a usage-syntax error.

An unusable character was encountered in the input stream.

Examples: `iconv` Command Conversion

Here are two simple examples:

- To convert the contents of the mail.x400 file from code set IBM-850 and store the results in the mail.local folder, enter the following:

  ```
  iconv -f IBM-850 -t ISO8859-1 mail.x400 > mail.local
  ```

- To convert the contents of a local file to the mail interchange format and send mail, enter the following:

  ```
  iconv -f IBM-943 -t fold7 mail.local > mail.fxrojas
  ```
